Part number: CM020005

Contents

Chapter 1: Introduction

About COMSOL Multiphysics	36
The COMSOL Multiphysics Modules and Interfacing Options	37
COMSOL Documentation and Help	38
About the Documentation Set.	38
The Help Window and Topic-Based Help	40
The Documentation Window	43
Searching Help and Documentation Content	44
The About COMSOL Multiphysics Box	46
Checking for Product Software Updates	47
Typographical Conventions	47
Overview of the Reference Manual	50

Chapter 2: The COMSOL Modeling Environment

The COMSOL Desktop	54
Basic Navigation	57
Adjusting Window Location and Size on the Desktop	58
The COMSOL Desktop Windows	62
The COMSOL Desktop Menus and Toolbars	64
Windows Toolbars and Menus	64
Cross Platform (macOS and Linux) Toolbars and Menus	65
Features Available on Toolbars and From Menus.	66
The Messages Window	71
About the COMSOL Model File Formats.	71
Saving COMSOL Files	73
Saving and Opening Recovery Files	74
The Root Settings and Properties Windows	75
Unit Systems	77
Searching and Finding Text	78
The Application Libraries Window	80
The Applications Folders	82
Running or Opening a Model or Application and Its Documentation	82
Downloading MPH-Files With Solutions	83
Searching the Application Libraries	83
The Application Library Update Window.	84
The Part Library Update Window	85
The Physics Interfaces	86
Introduction to the Physics Interfaces	86
Physics Groups and Subgroups.	86
Adding and Inserting Physics Interfaces	89
Physics Interface Guide	91
Common Physics Interface and Feature Settings and Nodes.	94

Creating a New Model	98
Open a New Window to Begin Modeling	98
The Model Wizard	98
Toolbars and Keyboard Shortcuts	103
Home Toolbar	103
Definitions Toolbar	106
Geometry Toolbar	108
Work Plane Modal Toolbar	112
Materials Toolbar	113
Physics Toolbar	114
OD Component Toolbar	115
Mesh Toolbar	116
Study Toolbar	118
Results Toolbar	119
Plot Group Contextual Toolbar	121
Report Group Contextual Toolbar	123
Template Group Contextual Toolbar	124
View Toolbar	124
Developer Toolbar	125
Keyboard Shortcuts	126

Chapter 3: Building a COMSOL Multiphysics Model

Building Models in the Model Builder	130
The Model Builder	130
About the Sequence of Operations	131
The Global Definitions Node	131
The Component Node	131
Adding Extra Dimensions to a Model	135
Branches and Subbranches in the Tree Structure	136
Settings and Properties Windows for Feature Nodes	139
Displaying Node Names, Tags, and Types in the Model Builder	141
Opening Context Menus and Adding Nodes	143
The Physics Nodes	144
Physics Interface Default Nodes	146
Physics Interface Node Context Menu Layout	146
Physics Exclusive and Contributing Node Types	148
Physics Node Status	149
Dynamic Nodes in the Model Builder	151
Physics Symbols	152
Errors and Warnings	155
Creating and Running Methods in Models	157
Method Calls	158
Creating and Using Settings Forms and Dialogs	158
Comparing Models and Applications	159
Working with Nodes in the Model Builder	161
Moving Nodes in the Model Builder	161
Copying, Pasting, and Duplicating Nodes	161
Undoing and Redoing Operations	162
Going to the Source Node	163

Clearing Sequences and Deleting Sequences or Nodes	163
Disabling or Enabling Nodes	164
Modeling Guidelines	165
Selecting Physics Interfaces	165
Using Symmetries	166
Effective Memory Management	166
Selecting an Element Type	167
Analyzing Model Convergence and Accuracy	168
Achieving Convergence When Solving Nonlinear Equations	168
Avoiding Strong Transients	169
Physics-Related Checks and Guidelines	169
Results With Unphysical Values	170
Multiphysics Modeling Approaches	173
Creating a Multiphysics Coupling	173
Advantages of Using the Multiphysics Coupling Features	175
The Add Multiphysics Window	175
The Multiphysics Branch	176
Uncoupling a Multiphysics Coupling	176
Model Inputs and Multiphysics Couplings	177
Specifying Model Equation Settings	179
Specifying Equation Coefficients and Material Properties	179
Modeling Anisotropic Materials	180
Specifying Initial Values	180
Equation View	181
Physics Nodes — Equation Section	184
Boundary Conditions	186
Boundary Condition Types	186
Physics Interface Boundary Types	188
Continuity on Interior Boundaries	188
Physics Interface Axial Symmetry Node	189
Constraint Reaction Terms	189
Constraint Settings	190
Excluded Surfaces, Excluded Edges, and Excluded Points	191
Weak Constraints	191
Periodic Boundary Conditions	193
Computing Accurate Fluxes	196
Flux Computation Methods	196
Flux Calculation Example — Heat Transfer Model	197
Using Load Cases	199
About Load Cases	199
Defining Load Groups and Constraint Groups	199
Load Group	201
Constraint Group	201
Defining and Evaluating Load Cases	202
Numerical Stabilization	204
About Numerical Stabilization in COMSOL	204
Consistent Stabilization and Inconsistent Stabilization Sections on Settings Windows	204

An Example of Stabilization	205
Stabilization Techniques	207
References for Stabilization Techniques	210
Using Units	211
Using Standard Unit Prefixes and Syntax	211
SI Base, Derived, and Other Units	213
Special British Engineering Units	217
Special CGSA Units	217
Special EMU Units	217
Special ESU Units.	218
Special FPS Units	219
Special IPS Units	219
Special MPa Units.	219
Special Gravitational IPS Units	219
Switching Unit System	220
About Temperature Units	220
About Editing Geometry Length and Angular Units	221
Units and Space Dimensions	221

Chapter 4: Customizing the COMSOL Desktop

Customizing a Model	224
Customizing the Desktop Layout.	224
Changing Fonts and the Desktop Language	225
Editing Node Properties, Names, and Labels	225
Custom Grouping of Nodes	227
Grouping Nodes by Space Dimension and Type	228
Setting the Unit System for Models	230
Checking and Controlling Products and Licenses Used	230
Preferences Settings	232
The Preferences Dialog Box.	232
Importing and Exporting Preferences	233
Advanced Physics, Study, and Results Sections	234

Chapter 5: Global and Local Definitions

Global Definitions, Geometry, Mesh, and Materials	238
Global Definitions	238
Geometry Parts	238
Mesh Parts	239
Global Materials	239
Definitions	240
About Parameters, Variables, Variable Utilities, and Expressions	241
Parameters	242
Parameter Cases	244
Variables	244
Variable Utilities	246

Common Model Inputs	246
Model Input	247
Participation Factors	248
Response Spectrum	248
Common Settings for the Definitions Nodes	249
Operators, Functions, and Constants	251
Unary, Binary, and List Operators and Their Precedence Rules	251
Mathematical and Numerical Constants	252
Mathematical Functions	252
Physical Constants	254
Built-In Operators	255
Predefined and Built-In Variables	274
Predefined Physics Variables	274
Variable Naming Convention and Namespace	274
Variable Classification and Geometric Scope	275
Built-In Global Variables	275
Geometric Variables, Mesh Variables, and Variables Created by Frames	277
Material Group Indicator Variables	282
Shape Function Variables	282
Solver Variables	285
Entering Ranges and Vector-Valued Expressions	285
Summary of Built-In Variables With Reserved Names	287
Mass Properties	292
Introduction	292
Mass Properties	292
Mass Contributions	294
Functions	295
Switch for Functions	295
About User-Defined Functions	295
Common Settings for the Function Nodes	296
Analytic	297
Elevation (DEM)	298
External	299
Gaussian Pulse	299
Image	300
Interpolation	301
MATLAB	306
Piecewise	306
Ramp	308
Random	308
Rectangle	309
Step	309
Thermodynamics Property Package	310
Triangle	310
Waveform	310
Specifying Discontinuous Functions	311
Matrices and Matrix Operations	313
Matrix	313
Matrix Inverse	313

Matrix Diagonalization	314
Matrix Decomposition (SVD)	314
Component Couplings and Coupling Operators	316
About Component Couplings	316
General Extrusion	322
Linear Extrusion	323
Boundary Similarity	323
One-Point Map	324
Two-Point Map	324
Edge Map	325
Identity Mapping	325
General Projection	325
Linear Projection	326
Integration	327
Average	328
Maximum and Minimum	328
Common Settings for Component Couplings	329
Coordinate Systems	331
About Coordinate Systems	331
Base Vector System	332
Boundary System	334
Reverse Normal	335
Domain Normal	335
Combined System	336
Cylindrical System	336
Mapped System	337
Rotated System	338
Spherical System	339
System from Geometry	340
Scaling System	341
Identity and Contact Pairs	342
About Identity and Contact Pairs	342
Identity Pairs	343
Contact Pair	345
Probes	347
About Probes	347
Common Settings for Probes	348
Domain Probe, Boundary Probe, and Edge Probe	349
Domain Point Probe	350
Boundary Point Probe	350
Point Probe Expression	351
Global Variable Probe	351
Infinite Elements, Perfectly Matched Layers, and Absorbing Layers	352
Simulation of Infinite Domains	352
Standard Geometry Configurations	353
Manual Settings for Nonstandard Geometries	356
Note on Availability	357
PML Implementation	357
PMLs in Multiphysics	359

Perfectly Matched Layer	359
Known Issues When Modeling Using PMLs	361
Infinite Element Implementation	362
Infinite Element Domain	363
Known Issues When Modeling Using Infinite Elements.	364
Absorbing Layer	365
References for PMLs and Infinite Element Domains	366
Reduced Models	367
Introduction	367
Reduced Model Inputs	367
Global Reduced Model Inputs	367
Importing Reduced Models	368
Reduced Model	368

Chapter 6: Visualization and Selection Tools

Working with Geometric Entities	372
About Geometric Entities	372
The Graphics Window.	374
Basic Selection Concepts	375
About Highlighted Geometric Entities in the Graphics Window	375
Selection Colors	378
About Selecting Geometric Entities	379
The Selection List Window	383
Selecting and Clearing Selection of Geometric Entities.	385
The Graphics Window Toolbar Buttons and Navigation	387
Using A 3D Mouse from 3Dconnexion	395
Creating Named Selections	397
Introduction	397
Creating Named Selections	399
Copying and Pasting Selection Lists	401
Adjacent	402
Ball	402
Box	404
Cylinder	404
Disk	405
Explicit.	406
Union, Intersection, Difference, and Complement	407
Creating Named Selections in the Geometry Sequence	408
Adjacent Selection (Geometry Sequences)	410
Ball Selection (Geometry Sequences)	410
Box Selection (Geometry Sequences)	411
Cylinder Selection (Geometry Sequences)	412
Disk Selection (Geometry Sequences)	412
Explicit Selection (Geometry Sequences)	413
Union Selection, Intersection Selection, Difference Selection, and Complement Selection (Geometry Sequences)	414
Cumulative Selections	415

User-Defined Views	417
View (1D and 2D)	417
Axis (2D and 2D Axisymmetric)	418
Axis (1D and 1D Axisymmetric)	419
View (3D)	419
Camera	421
About the 3D View Light Sources and Attributes.	423
Directional Light	424
Point Light	426
Spotlight	427
Headlight	428
Hide for Geometry	429
Hide for Physics	430
Hide for Mesh Import	430
Chapter 7: Geometry Modeling and CAD Tools	
Creating a Geometry for Analysis	434
Overview of Geometry Modeling Concepts.	434
Techniques for Creating Geometries	435
Associative Geometry and Selections of Geometry Objects	436
Choosing the Right Space Dimension	436
Removing Interior Boundaries	438
Working with Geometry Sequences	439
The Geometry Nodes	439
The Geometry Toolbar	439
The Geometry Node	442
Plane Geometry	443
Creating a Geometry Sequence	444
Editing and Building Geometry Nodes	446
Exporting a Geometry	447
Measuring Geometry Objects	448
The Form Union/Assembly Node — Uniting the Geometry.	449
Using Geometry Parts	451
Geometry Part Settings	453
Loaded Part Settings	453
Local Parameters	454
Part Libraries	455
Introduction.	455
Using Part Libraries	455
Creating a Part.	458
Geometric Primitives	460
Bézier Polygon.	461
Block	463
Circle	464
Cone	465
Cylinder	467
Eccentric Cone	468
Ellipse	469

Ellipsoid	470
Helix	471
Hexahedron	474
Interpolation Curve	474
Interval	476
Line Segment	477
Parametric Curve	477
Parametric Surface	479
Point	480
Polygon	481
Pyramid	483
Rectangle	484
Sphere	485
Square	486
Tetrahedron	487
Torus	488
Composite Object (Backward Compatibility)	489
 Geometry Operations	 490
Array	493
Chamfer	494
Compose	495
Convert to Curve	496
Convert to Point	497
Convert to Solid	498
Convert to Surface	499
Copy	500
Cross Section	501
Deformed Configuration	502
Delete Entities	502
Difference	503
Edit Object	504
Extrude	506
Fillet	507
If, Else If, Else, End If	508
Import	509
Intersection	511
Mirror	512
Move	513
Parameter Check	514
Part Instance	515
Partition Objects	516
Partition Domains	518
Partition Edges	519
Partition Faces	520
Revolve	521
Rotate	522
Scale	523
Split	524
Sweep	525
Tangent	527
Union	528
Work Plane	529
Using Work Planes	534

Virtual Geometry and Mesh Control Operations	537
Collapse Edges	538
Collapse Faces	538
Collapse Face Regions	539
Form Composite Domains	539
Form Composite Edges	539
Form Composite Faces	540
Ignore Edges	540
Ignore Faces	541
Ignore Vertices	541
Merge Edges	542
Merge Vertices	542
Mesh Control Domains	542
Mesh Control Edges	543
Mesh Control Faces	543
Mesh Control Vertices	543
Remove Details	544
Geometry Modeling Examples	546
Creating a 2D Geometry Model	546
Creating a 3D Geometry Model	551
Forming Composite Edges and Faces by Ignoring Vertices and Edges	559
Merging Vertices by Collapsing Edges	563

Chapter 8: Meshing

Creating a Mesh for Analysis	568
Meshing Concepts	568
Mesh Elements for 1D, 2D, and 3D Geometries	569
Free (Unstructured) Meshing	570
Structured Meshes	571
About Swept Meshes	571
Mesh Control Entities	573
The Mesh Toolbar	573
Adding, Editing, and Building Meshing Sequences	575
Mesh (Node)	575
Using Mesh Parts	576
Mesh Part Settings	577
Meshes Generated by Adaptation	577
The Mesh Statistics Window	577
Meshing Techniques	579
Choosing a Meshing Sequence Type	579
Mesh Element Quality and Size	580
Avoiding Inverted Mesh Elements	582
Troubleshooting Boundary Layer Mesh Generation	583
Troubleshooting Free Tetrahedral Mesh Generation	584
Meshing Operations and Attributes	585
Adapt	586
Boundary Layers	589
Boundary Layer Properties	590

Convert	591
Corner Refinement	591
Copy Domain	592
Copy Edge	594
Copy Face	595
Copy	596
Distribution	597
Edge	598
Edge Groups	599
Edge Map	599
Free Quad	599
Free Tetrahedral	600
Free Triangular	602
Mapped	603
One-Point Map	604
Reference	605
Refine	605
Scale	606
Size	607
Size Expression	609
Swept	612
Two-Point Map	614
Importing and Exporting Meshes	615
About Mesh Export, Import, and Operations on Imported Meshes	615
Exporting Meshes	615
Importing Meshes	616
Creating Geometry from Mesh	617
Operations on Imported Meshes	618
Using Operations on an Imported Mesh	618
Ball	621
Box	621
Create Vertex	622
Cylinder	622
Delete Entities	623
Detect Faces	623
Finalize	624
Import	624
Join Entities	626
Logical Expression	627
Meshing Examples	628
Generating a 3D Swept Mesh	628
Using Mesh Control Entities to Control Element Size	630
Using Structured and Unstructured Mesh with Boundary Layers	631

Chapter 9: Materials

Materials Overview	636
About Materials and Material Properties	636
About the Material Databases	637
About Using Materials in COMSOL Multiphysics	638

Working with Materials	642
The Material Browser Window	642
The Add Material Window	643
Materials	645
The Settings Window for Material	646
Property Groups	650
Material Link	653
Switch for Materials	653
Layered Material	654
Layered Material Link	658
Layered Material Stack	660
Layered Material Link (Subnode)	662
Single Layer Material	662
Material Properties Reference	664
About Model Inputs	664
About the Output Material Properties	664
Acoustics Material Properties	666
Electrochemistry Material Properties	667
Electromagnetic Models	668
Equilibrium Discharge	669
Gas Models	670
Piezoelectric Models	670
Piezoresistive Models	670
Semiconductors Material Properties	671
Solid Mechanics Material Properties	675
Solid Mechanics Material Properties: Nonlinear Structural Materials Module	676
Solid Mechanics Material Properties: Fatigue Module	680
Solid Mechanics Material Properties: Geomechanics Material Model	681
Thermal Expansion Material Properties	682
External Material Properties	682
User-Defined Materials and Libraries	683
Importing a Material Library	683
Creating a New Material Library and Adding and Editing Materials	683
Restoring a Deleted User-Defined Library	686
Using Functions in Materials	687
Adding a Function to the Material	687
Defining an Analytic Function	687
Working with External Materials	690
The External Material Model	690
Using External Materials in Physics Interfaces	690
Built-in Material Function Interface Types	692
Library of Utility Functions for Solid Mechanics	697
How to Compile and Link an External Material Model	698
Known Issues for External Materials	699
External Material	699
Module-Specific Material Databases	702
AC/DC Materials Database	702
Batteries and Fuel Cells Materials Database	703
Bioheat Materials Database	704

Building Materials Database	704
Equilibrium Discharge Materials Database	705
Liquids and Gases Materials Database	705
MEMS Materials Database	706
Nonlinear Magnetic Materials Database	707
Piezoelectric Materials Database	710
Piezoresistivity Materials Database	711

RF Materials Database	712
Semiconductor Materials Database	712
Thermoelectric Materials Database	712
References for the Materials Databases	712

Chapter 10: The AC/DC Interfaces

The Electromagnetics Interfaces	718
Fundamentals of Electromagnetics	
Maxwell's Equations.	719
Constitutive Relations	719
Potentials.	720
Material Properties	721
About the Boundary and Physics Interface Conditions	721
Phasors	722
Effective Nonlinear Magnetic Constitutive Relations.	723
Electromagnetic Forces	723
References for Electromagnetic Theory	723
Theory of Electrostatics	
Charge Relaxation Theory	724
Electrostatics Equations	725
The Electrostatics Interface in Time Dependent or Frequency Domain Studies	726
Theory of Electric Currents	
Electric Currents Equations in Steady State	727
Theory of Magnetic Fields	
Magnetostatics Equation	728
Frequency Domain Equation	728
Transient Equation	729
Maxwell's Equations.	729
Magnetic and Electric Potentials	729
Gauge Transformations	730
Selecting a Particular Gauge	730
The Gauge and Equation of Continuity for Dynamic Fields	730
Time-Harmonic Magnetic Fields	730
The Electrostatics Interface	
Domain, Boundary, Edge, Point, and Pair Nodes for the Electrostatics Interface	733
Charge Conservation	735
Initial Values.	735
Space Charge Density	735

Zero Charge	735
Ground	736
Electric Potential	736
Surface Charge Density	736
External Surface Charge Accumulation	737
Electric Displacement Field	737
Periodic Condition	737
Thin Low Permittivity Gap	738
Line Charge	738
Line Charge (on Axis)	739
Line Charge (Out-of-Plane)	739
Point Charge	740
Point Charge (on Axis)	740
Change Cross Section	741
Change Thickness (Out-of-Plane)	741
Charge Conservation, Piezoelectric	741
The Electric Currents Interface	743
Domain, Boundary, Edge, Point, and Pair Nodes for the Electric Currents Interface	744
Current Conservation	745
Initial Values.	746
External Current Density	747
Current Source	747
Electric Insulation.	747
Boundary Current Source	748
Normal Current Density	748
Distributed Impedance.	748
Contact Impedance	749
Sector Symmetry.	750
Line Current Source	750
Line Current Source (on Axis).	751
Point Current Source	751
Point Current Source (on Axis)	752
Piezoresistive Material	752
The Magnetic Fields Interface	753
Domain, Boundary, Point, and Pair Nodes for the Magnetic Fields Interface.	754
Ampère's Law	755
Ampère's Law, Magnetostrictive	757
Initial Values.	757
External Current Density.	758
Velocity (Lorentz Term)	758
Magnetic Insulation	759
Magnetic Field	759
Surface Current Density	760
Magnetic Potential	760
Perfect Magnetic Conductor	760
Line Current (Out-of-Plane)	761
Line Current (on Axis).	761

Chapter II: The Pressure Acoustics Interface

Fundamentals of Acoustics	764
Acoustics Explained	764
Examples of Standard Acoustics Problems	764
Different Acoustic Interfaces	765
Mathematical Models for Acoustic Analysis	766
The Pressure Acoustics, Frequency Domain Interface	768
Domain, Boundary, Edge, Point, and Pair Nodes for the Pressure Acoustics, Frequency Domain Interface	770
Pressure Acoustics	771
Sound Hard Boundary (Wall)	771
Initial Values	772
Monopole Source	772
Dipole Source	772
Normal Acceleration	772
Sound Soft Boundary	773
Pressure	773
Impedance	773
Symmetry	773
Plane Wave Radiation	774
Spherical Wave Radiation	774
Cylindrical Wave Radiation	774
Incident Pressure Field	774
Interior Sound Hard Boundary (Wall)	775
Periodic Condition	775
Axial Symmetry	775
Continuity	776
Theory for Pressure Acoustics, Frequency Domain	777
Frequency Domain Study	777
Eigenfrequency Study	778
References for the Pressure Acoustics, Frequency Domain Interface	778

Chapter 12: The Chemical Species Transport Interfaces

Theory for Transport of Diluted Species	782
Mass Balance Equation	782
Equilibrium Reaction Theory	783
Convective Term Formulation	784
Solving a Diffusion Equation Only	784
Mass Sources for Species Transport	785
Adding Transport Through Migration	786
Supporting Electrolytes	787
Crosswind Diffusion	787
Danckwerts Inflow Boundary Condition	788
References	788
The Transport of Diluted Species Interface	790
The Transport of Diluted Species in Porous Media Interface	793
Domain, Boundary, and Pair Nodes for the Transport of Diluted Species Interface	794
Transport Properties	795

Turbulent Mixing	796
Initial Values	797
Mass-Based Concentrations	797
Reactions	797
No Flux	798
Inflow	798
Outflow	799
Concentration	799
Flux	799
Symmetry	800
Flux Discontinuity	800
Partition Condition	800
Periodic Condition	801
Line Mass Source	801
Point Mass Source	802
Open Boundary	802
Thin Diffusion Barrier	802
Thin Impermeable Barrier	802
Equilibrium Reaction	803
Surface Reactions	803
Surface Equilibrium Reaction	804
Fast Irreversible Surface Reaction	804
Porous Electrode Coupling	804
Reaction Coefficients	805
Electrode Surface Coupling	805
Porous Media Transport Properties	805
Adsorption	807
Partially Saturated Porous Media	807
Volatilization	809
Reactive Pellet Bed	810
Reactions	811
Species Source	812
Hygroscopic Swelling	812
Fracture	813
The Reacting Flow, Diluted Species Multiphysics Interface	814
The Reacting Laminar Flow, Diluted Species Interface	814
The Reacting Flow, Diluted Species Coupling Feature	815
Physics Interface Features	816

Chapter 13: The Fluid Flow Interface

Theory of Laminar Flow	818
General Single-Phase Flow Theory	818
Compressible Flow	820
Weakly Compressible Flow	820
The Mach Number Limit	820
Incompressible Flow	821
The Reynolds Number	821
Theory for the Wall Boundary Condition	822
Prescribing Inlet and Outlet Conditions	822
Normal Stress Boundary Condition	823

Pressure Boundary Condition	824
Mass Sources for Fluid Flow.	825
Numerical Stability — Stabilization Techniques for Fluid Flow	826
Solvers for Laminar Flow	828
Pseudo Time Stepping for Laminar Flow Models	829
Discontinuous Galerkin Formulation	830
Particle Tracing in Fluid Flow	830
References for the Single-Phase Flow, Laminar Flow Interfaces	831

Glossary of Terms	1562
--------------------------	-------------

Introduction

Welcome to the COMSOL Multiphysics® simulation software! This book details features and techniques that help you throughout all COMSOL Multiphysics modeling in version 5.4 using the COMSOL Desktop® environment. For example, detailed information about how to build geometries in COMSOL Multiphysics, how to create a mesh for the analysis, how to create parameters and variables used within a model, how to add the physics interfaces and material properties, and how to solve and display the results are all explained. The full set of documentation shows you, step by step, how to tap into the functions and capabilities in the COMSOL Multiphysics software. This introductory chapter provides an overview of COMSOL Multiphysics and its product family, documentation set, and other resources.

Version 5.4 introduces the *COMSOL Compiler* for creating standalone apps and contains further enhanced *Application Builder* and *COMSOL Server™* products for creating and deploying custom apps based on COMSOL Multiphysics.

In this chapter:

- [About COMSOL Multiphysics](#)
- [COMSOL Documentation and Help](#)
- [Overview of the Reference Manual](#)

About COMSOL Multiphysics

COMSOL Multiphysics is a powerful interactive simulation environment used to model and solve all kinds of scientific and engineering problems. The software provides a powerful integrated desktop environment with a *Model Builder* that gives you a full overview of the model and access to all functionality. With COMSOL Multiphysics you can easily extend conventional models for one type of physics into multiphysics models that solve coupled physics phenomena — and that do so simultaneously. Accessing this power does not require an in-depth knowledge of mathematics or numerical analysis.

Using the built-in *physics interfaces* and the advanced support for material properties, you can build models by defining the relevant physical quantities — such as material properties, loads, constraints, sources, and fluxes — rather than by defining the underlying equations. You can always apply these variables, expressions, or numbers directly to solid and fluid domains, boundaries, edges, and points independently of the computational mesh. The COMSOL Multiphysics software then internally compiles a set of equations representing the entire model.

You access the power of COMSOL Multiphysics as a standalone product through a flexible graphical user interface (GUI), in applications created using the Application Builder and deployed using the COMSOL Compiler or COMSOL Server™, or by script programming in Java® or the MATLAB® language (this requires a LiveLink™ for MATLAB® license).

Using these physics interfaces, you can perform various types of studies including:

- Stationary and time-dependent (transient) studies
- Linear and nonlinear studies
- Eigenfrequency, modal, and frequency response studies

When solving the models, the COMSOL Multiphysics software assembles and solves the problem using a set of advanced numerical analysis tools. The software runs the analysis together with adaptive mesh refinement (if selected) and error control using a variety of numerical solvers. The studies can make use of multiprocessor systems and cluster computing, and you can run batch jobs and parametric sweeps.

The COMSOL Multiphysics software creates *sequences* to record all steps that create the geometry, mesh, physics, studies and solver settings, and visualization and results presentation. This makes it easy to parameterize any part of the model; simply change a node in the model tree and rerun the sequences. The program remembers and reapplies all other information and data in the model.

REAL-WORLD APPLICATIONS

Partial differential equations (PDEs) form the basis for the laws of science and provide the foundation for modeling a wide range of scientific and engineering phenomena. You can use the COMSOL Multiphysics software in many application areas, including:

- Acoustics
- Bioscience
- Chemical reactions
- Corrosion and corrosion protection
- Diffusion
- Electrochemistry
- Electrodeposition
- Electromagnetics
- Fatigue analysis
- Fluid dynamics
- Fuel cells and batteries
- Geophysics and geomechanics
- Heat transfer
- Layered shells and composite materials
- Microelectromechanical systems (MEMS)
- Microfluidics
- Microwave engineering
- Multibody dynamics
- Optics
- Optimization and sensitivity analysis
- Particle tracing
- Photonics
- Piezoelectric devices
- Pipe flow
- Plasma physics
- Porous media flow
- Quantum mechanics
- Radio-frequency components
- Ray tracing and ray optics
- Rotordynamics
- Semiconductor devices
- Structural mechanics
- Transport phenomena
- Wave propagation

Many real-world applications involve simultaneous couplings in a system of PDEs — *multiphysics*. For instance, the electric resistance of a conductor often varies with temperature, and a model of a conductor carrying current should include resistive-heating effects. The [Multiphysics Modeling Approaches](#) section discusses multiphysics modeling techniques. Predefined multiphysics interfaces provide easy-to-use entry points for common multiphysics applications.

In its base configuration, COMSOL Multiphysics offers modeling and analysis power for many application areas. For several of the key application areas there are also optional add-on modules. These application-specific modules use terminology, solution methods, and plot types specific to the particular discipline, which simplifies creating and analyzing models. The modules also include comprehensive Application Libraries with example models that show the use of the product within its application areas.

The COMSOL Multiphysics Modules and Interfacing Options

The optional modules, including interfacing options such as the CAD Import Module and bidirectional interfaces such as the LiveLink™ products, are optimized for specific application areas and offer discipline-standard terminology and physics interfaces. For some modules, additional material libraries, specialized solvers, element types, and visualization tools are also available.

For up-to-date module availability, product descriptions, and a specification chart, go to www.comsol.com/products.

COMSOL Documentation and Help

About the Documentation Set

The full documentation set that ships with COMSOL Multiphysics consists of the following titles:

- *Introduction to COMSOL Multiphysics* — information about version 5.4 and how to build models using the desktop environment, including quick references to keyboard shortcuts and common commands and functions.
- *COMSOL License Agreement*.
- *COMSOL Multiphysics Installation Guide* — besides covering various installation options, it describes system requirements and how to configure and run the COMSOL Multiphysics software on different platforms, including client-server architectures as well as shared-memory and distributed (cluster) parallel versions.
- *COMSOL Multiphysics Reference Manual* — this book, which covers the functionality of COMSOL Multiphysics across its entire range from geometry modeling to results evaluation and visualization, including the physics interfaces for physics and equation-based modeling. It serves as a tutorial and a reference guide to use COMSOL Multiphysics. This book reviews geometry, mesh, solver, and results functionality and provides detailed information about the settings and options. Additionally, it describes some advanced functionality and settings in COMSOL Multiphysics and provides background material and references.
- *COMSOL Multiphysics Programming Reference Manual* — this book provides details about features and techniques that help you control COMSOL Multiphysics using its application programming interface (API). The COMSOL API can be used from the Application Builder, in a standalone Java® application, and from MATLAB® using the LiveLink™ for MATLAB® interface. For the Application Builder, the *Application Programming Guide* provides information about using the COMSOL API and the API of the Application Builder components to create methods for custom applications.
- The *Introduction to the Application Builder* and the *Application Builder Reference Manual* provide documentation related to the Application Builder and how to create and deploy simulation apps and how to use the COMSOL Compiler to create standalone runnable apps. See also the *COMSOL Server Manual* for configuring a server and clients for COMSOL Multiphysics applications.
- *COMSOL Server Manual* — information about setting up, configuring, and running a COMSOL Server for running and deploying applications within an organization.
- The *Physics Builder Manual* provides documentation related to the Physics Builder for creating custom physics interfaces.
- The *Essentials of Postprocessing and Visualization* and *Specialized Techniques for Postprocessing and Visualization* provide tips and information that help you get the most out of the postprocessing and visualization tools in COMSOL Multiphysics.
- *COMSOL Multiphysics Release Notes* — information about new functionality and changes in the 5.4 release and about compatibility with earlier versions of COMSOL Multiphysics.

In addition, each of the optional modules includes a manual as described in [The COMSOL Multiphysics Modules and Interfacing Options](#). The documentation for the optional CAD Import Module and LiveLinks to CAD packages is available in separate manuals, and the documentation for the optional Material Library in the *Material Library User's Guide*.

The *COMSOL LiveLink™ for MATLAB® User's Guide* shows how to access the capabilities of COMSOL from the MATLAB programming environment.

DIFFERENT INSTRUCTIONS FOR DIFFERENT OPERATING SYSTEMS

The Windows® platform uses a ribbon layout, a style familiar to Microsoft® Office users and integrated into many other Windows software designs. The ribbon-style layout is intuitive and makes it easy to locate similar and frequently used features. For the Linux® and macOS platforms, there are extended toolbars that provide almost identical single-click access to most functionality in the software.

The use of the ribbon for Windows users means that there are slightly different instructions about how to access some features compared to macOS or Linux users. When specific instructions are included about where to find a particular feature, the instructions distinguish between the operating systems using different icons.

- Where there are no differences, the icons are not used.
- Where there are minor differences in appearance or accessibility, but the functionality is the same, no icons are used.
- In general, instructions for all platforms imply that the feature is available from a named toolbar. For example, the **Home** toolbar, **Physics** toolbar, **Mesh** toolbar, or **Geometry** toolbar. See [Toolbars and Keyboard Shortcuts](#) for information about each toolbar.

A *ribbon tab*, *ribbon group*, or *modal ribbon tab*, are available in the Windows version. See [Figure 2-1](#) for an example of the Windows **Home** toolbar.

The *Model Toolbar* and *Contextual Toolbar* are available in the cross-platform version, primarily for macOS and Linux users. See [Figure 2-11](#) for an example of these toolbars.

ABOUT THE SCREENSHOTS USED IN THIS MANUAL

The screenshots used throughout this reference manual are captured using the Windows platform except when there are clear differences other than fonts or cosmetic appearance.

ADDITIONAL INTERNET RESOURCES

A number of internet resources have more information about COMSOL, including licensing and technical information. The electronic documentation, topic-based (or context-based) help, and the application libraries are all accessed through the COMSOL Desktop.

If you are reading the documentation as a PDF file on your computer, the [blue links](#) do not work to open an application or content referenced in a different guide. However, if you are using the Help system in COMSOL Multiphysics, these links work to open other modules, application examples, and documentation sets.

CONTACTING COMSOL BY EMAIL

For general product information, contact COMSOL at info@comsol.com.

COMSOL ACCESS AND TECHNICAL SUPPORT

To receive technical support from COMSOL for the COMSOL products, please contact your local COMSOL representative or send your questions to support@comsol.com. An automatic notification and a case number are

sent to you by email. You can also access technical support, software updates, license information, and other resources by registering for a COMSOL Access account.

COMSOL ONLINE RESOURCES

COMSOL website	www.comsol.com

Support Knowledge Base	www.comsol.com/support/knowledgebase

The Help Window and Topic-Based Help

The **Help** window is useful as it is connected to many of the features in the COMSOL Desktop. This concept is called *topic-based help* or *context help*. You can also search and access all the HTML documentation content from this window.

The **Help** system automatically starts a web server using port 8090 on the computer where COMSOL Multiphysics is installed. Depending on the security settings, you might get a question to allow that port to be used the first time the help system is started.

The operating system might also issue a firewall security warning. To use Help, allow COMSOL Multiphysics access through the firewall.

To learn more about a node in the Model Builder, or a window on the Desktop, click to highlight a node or window, then press F1. The **Help** window opens and displays the topic information about the selected feature.

OPENING THE HELP WINDOW AND THE TOPIC-BASED HELP

There are several ways to open the **Help** window:

- Press F1.
- In the main toolbar, click **Help** ().
- In the upper-right corner of the COMSOL Desktop, click the () button.
- From the main menu, select **File>Help** (Windows) **Help>Help** (Linux and macOS).
- Right-click any node in the **Model Builder** and select **Help**.

ABOUT USING THE F1 KEY TO ACCESS CONTEXT HELP

To display topic-based (context) information in the **Help** window, on the COMSOL Desktop:

- Click to highlight a node in the Model Builder tree. For example, the **Component** or **Geometry** node.

- Click a window tab, for example, **Model Builder**, **Add Study**, or **Messages**.
- For Windows users, hover over ribbon buttons or menu items to display a *tooltip*. While the tooltip is showing, you can press F1 to display more detail.

At the top of the **Help** window you find the tools and search functionality listed in the table below. Also, above the help text, a clickable breadcrumb trail shows the location of the displayed contents in the COMSOL documentation set. Click any part of the trail to move to that level in the COMSOL documentation.

	In some cases you need to refocus the context help on its target before pressing F1. Try clicking to highlight a node, a window, or the button or click to focus on the Help window, hover over a toolbar button (Windows only) and press F1.
---	---

TABLE I-I: THE HELP AND DOCUMENTATION TOOLBARS

BUTTON	NAME	DESCRIPTION
		Click the Home button or select the COMSOL Documentation top node in the table of contents tree to return to the COMSOL Documentation window home page. Not available when showing context help in the Help window.
	Show Table of Contents/ Show Topic	When a help topic page is shown in the Help window, click Show Table of Contents to open a tree-based menu of the COMSOL documentation. When you select a node in the table of contents tree the corresponding topic is shown on the topic page. Alternatively, click again (Show Topic) to return to the topic page.
	Search	On the Help window, click to open the search engine to look for contents in the COMSOL documentation. Search results are shown sorted by product. On the Documentation window, enter search terms in the field and choose the Search scope — All documents, Selected only, or Application libraries . See Searching Help and Documentation Content for more information about search terms you can use.
	Back	Navigates backward to the previous page in the Help or Documentation window's browser history.
	Forward	Navigates forward in the browser history, but only to the end of the current list.
	Sticky Help	On the Help window, click the Sticky Help button to lock the current help window (the icon is highlighted ) , which can be useful to keep some help topic or model instruction active, or to release the window and view topic-based (context) help when a node or window is clicked.
	Show in External Browser	On the Help window, click the Show in External Browser button to show the current help topic in an external web browser.
	Previous Section	Navigates backward to the previous section in the documentation.
	Next Section	Navigates forward to the next section in the documentation.

CHANGING THE DEFAULT DOCUMENTATION AND HELP SETTINGS

To edit the following settings, open [The Preferences Dialog Box](#) and click **Help**.

Locate the **Target** area and choose **Documentation window** (the default) from the **Show documentation in** list to show the help contents in the **Documentation** window that is included in the COMSOL Desktop environment (default), or select **External browser** to display the help contents in a separate web browser. For further details on how to access and use the documentation, see the section [The Documentation Window](#) below. Similarly, using the **Show help in** list, you can choose between **Help window** (default) and **External browser** to show topic-based help in the **Help**

window inside the COMSOL Desktop or in an external web browser, respectively. When showing topic-based help in an external browser, you need to press F1, choose **Help>Help**, or select the **Help** context menu item (when applicable) to trigger an update of the browser's contents. The **PDF-file target** setting controls what happens when you click a PDF link on the COMSOL Documentation entry page. Choose **In place** to display PDF documents using the native browser's PDF display settings, or choose **New window** to launch them in the default system application for PDF-files. On Windows, the native browser is always Microsoft Edge or Internet Explorer.

In the **Source** area, set the **Location** to **Local** to display help using locally installed help files or to **Online** to access help from the COMSOL web site. For the **Local** option, edit the **Documentation root directory** file path as required. The default file paths are based on the platform:

- On Windows C:\Program Files\COMSOL\COMSOL54\Multiphysics\doc, or generically COMSOL54\doc.
- For macOS and Linux, under the main COMSOL installation directory: COMSOL54/Multiphysics/doc.

Proxy Server Settings

If you connect to the internet through a web proxy, you can use the controls in the **Proxy server settings** area to specify the proxy server settings to use when communicating with the COMSOL website for displaying online help in integrated mode as well as for performing updates of the COMSOL Application Library and the COMSOL Part Library (see [The Application Library Update Window](#) and [The Part Library Update Window](#) for further details about these services).

The **Configuration** list has the following options:

- **No proxy server:** Connect to the update server directly, bypassing any proxies. This is the default setting.
- **Use system settings:** Use the system-wide proxy server settings defined on your computer.
- **Manual:** Choose this alternative if you want to specify a proxy server by entering the name (or IP address) and port number in the **Server** and **Port number** fields. The default port number is 443, which is the default for HTTP secure (HTTPS). If the proxy server requires authentication, you are asked to provide username and password the first time in each COMSOL session you access documentation or update the COMSOL Application Library or Part Library.

Selecting a Web Browser

In the **General** section of the **Preferences** dialog, under **Web browser** (Windows and Linux only), you can choose which browser the COMSOL Multiphysics software should use to show pages on the COMSOL website and documentation when using the web browser mode. The following settings are available:

- On Windows: Choose the **Program** setting **System default** to use the default system web browser. Alternatively, choose **Custom** and then give the path to an **Executable** location for a different browser installed on your computer.
- On Linux: Type the path to the web browser directly in the **Executable** field, or click the **Browse** button and then point to the executable file on the file system.

On macOS, this setting is not available, and COMSOL Multiphysics always uses the system's default web browser.

The Documentation Window

 Win	To open the Documentation window: <ul style="list-style-type: none">• Press Ctrl+F1.• From the File menu, select Help>Documentation.
 Mac  Linux	To open the Documentation window: <ul style="list-style-type: none">• Press Ctrl+F1• In the main toolbar, click the Documentation () button.• From the Help menu, select Documentation.

In the Documentation window (or a browser window, depending on your preference settings), you can navigate to PDF or HTML versions of the documentation (availability is based on your license), as well as search all the documentation, save or open PDFs, or view the HTML content in this window. There are different ways to access the same information using either the left-hand side ([Figure 1-1](#)) or right-hand side ([Figure 1-2](#)) of the window.

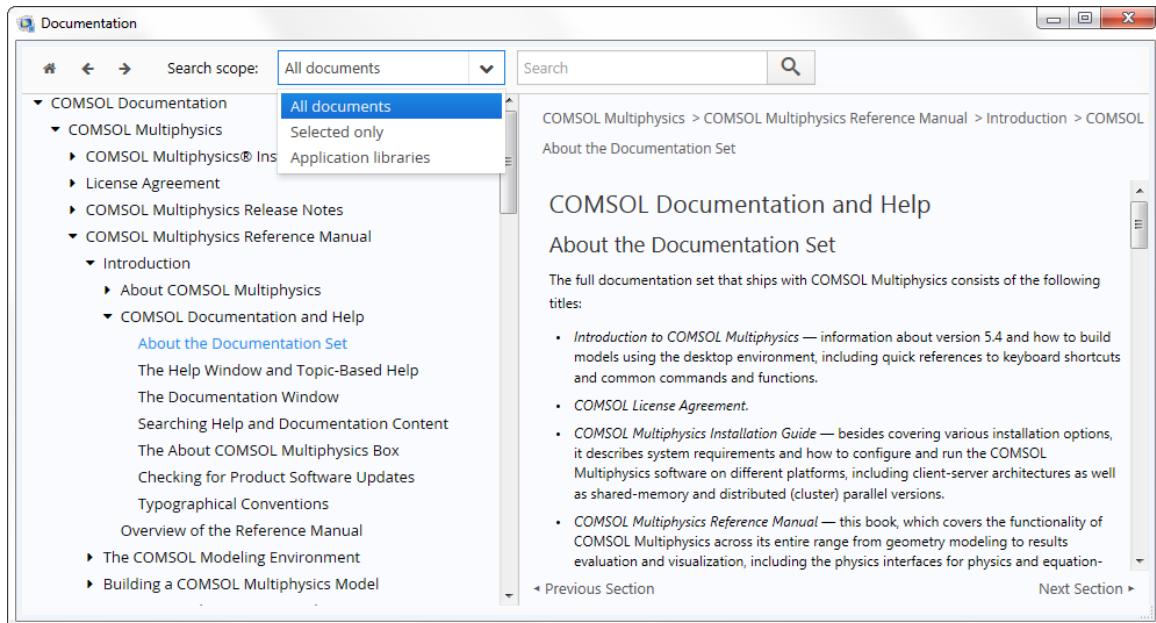

Figure 1-1: Based on your license, links to the HTML versions of the product documentation are accessed and can be browsed in the tree. When you click a topic in the tree the information displays to the right. You can also adjust the search scope.

COMSOL Documentation

COMSOL Multiphysics	
Installation Guide	[HTML PDF]
COMSOL Software License Agreement	[HTML PDF]
COMSOL Release Notes	[HTML PDF]
Introduction to COMSOL Multiphysics	[PDF]
Introduction to Application Builder	[PDF]
Application Builder Reference Manual	[HTML PDF]
Application Programming Guide	[PDF]
Essentials of Postprocessing and Visualization	[PDF]
Specialized Techniques for Postprocessing and Visualization	[PDF]
Reference Manual	[HTML PDF]
Physics Builder Manual	[HTML PDF]
Programming Reference Manual	[HTML PDF]

Figure 1-2: Based on your license, links to PDF and HTML versions of the product documentation are accessed from this window. When you click HTML it jumps to the first page of the documentation for that product; when you click PDF you can Open or Save a full PDF version of that document.

- [The Help Window and Topic-Based Help](#)
- [Table 1-1](#) for a list of the Documentation toolbar buttons.

Searching Help and Documentation Content

After you open [The Help Window and Topic-Based Help](#), click the Search button () to open the search engine and search the HTML content. Search results are shown sorted by product. You can also search in the contents of [The Documentation Window](#).

SEARCHING THE DOCUMENTATION

On the **Documentation** window, you can adjust the **Search scope** (see [Figure 1-1](#)). Enter a search term in the **Search expression** field and then select **All documents**, **Selected only**, or **Application libraries** from the list to narrow or expand the search scope as needed. For **Selected only** ([Figure 1-3](#)), first click a branch in the tree (for example, **COMSOL Multiphysics Reference Manual**) and then the search includes all the documents below the selected node until the beginning of the next branch. In this example it searches until the end of the Troubleshooting License Errors section.

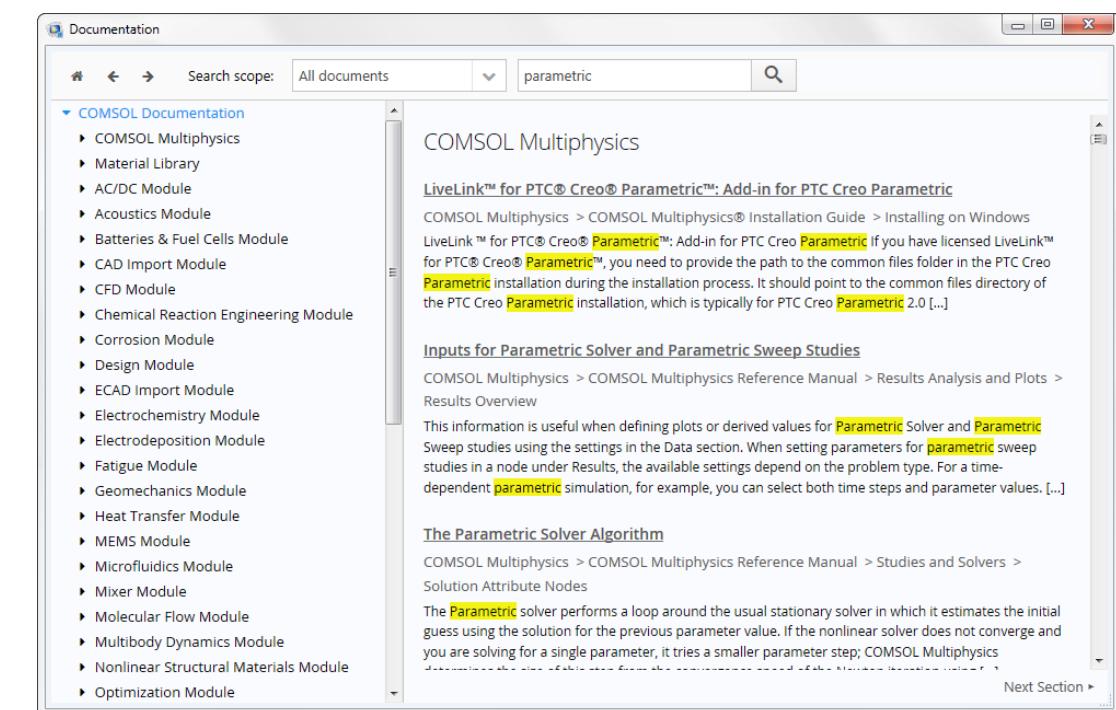

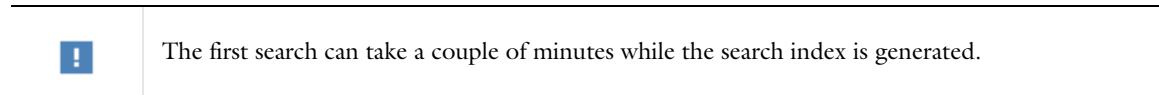

Figure 1-3: When searching in the Documentation window, choose a Search scope to search only a selected portion of the documentation, all the documentation, or only the Application Libraries.

SEARCH PARAMETERS FOR HELP AND THE DOCUMENTATION

Some examples of search parameters you can use:

TABLE I-2: SEARCH PARAMETERS FOR THE COMSOL HELP SYSTEM

OPERATOR	EXAMPLE	SEARCH RESULT EXAMPLE
&&, AND	block && cone block AND cone	Results include all instances of the words.
OR,	block OR cone block cone	Results include any of the listed words.
+, -	+block -cone	Search for one term (+block) but not the other term (-cone).
~, ~	"plot line"~10	Search for the words enclosed in the quotation marks (plot line) within (~) a certain number of words (10) from each other.
~	excentric~	Search for something "almost" spelled in a particular way. For example, excentric. The results include eccentric cone.

TABLE I-2: SEARCH PARAMETERS FOR THE COMSOL HELP SYSTEM

OPERATOR	EXAMPLE	SEARCH RESULT EXAMPLE
?	h?t	Use in a search query to mean exactly one character. For example, search for all instances of hat, hit, or hut where ? represents a, i, or u, or any other letter between h and t.
*	strain* strain*d	The asterisk (*) is a wildcard character. Search for any word that starts with “strain”. Results include strain-based, strain-rate, or strain, for example. The asterisk represents any number of characters. If the asterisk is used in the middle of the word, it searches for one letter between “n” and “d”. The result in this example is strained. You can use the asterisk before and after the word in order to search for it in the middle of a longer word or expression, For example, *setdefaultgeometry* finds ModelUtil.setDefaultGeometryKernel.
enclosed quotation marks “ ”	“time dependent study”	Use quotation marks around a text string to search for exactly that phrase; that is, to search for the words in the order given within the quotation marks.

The About COMSOL Multiphysics Box

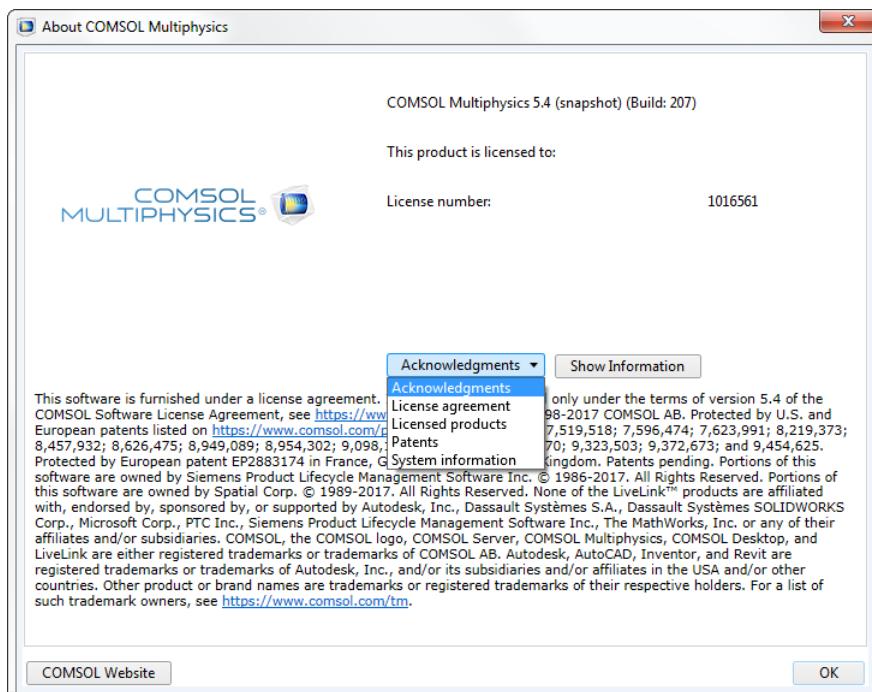

Figure 1-4: The About COMSOL Multiphysics dialog box with the Acknowledgments list.

To open the **About COMSOL Multiphysics** (≡) window:

- For Windows users, select it from the **File** menu.
- For macOS and Linux (cross platform) users, choose it from the **Help** menu.

In addition to copyright and patent information, the **About COMSOL Multiphysics** dialog box has the following information:

- The **Version number**
- The user or company **This product is licensed to**
- The **License number**

Select an option from the list below and then click **Show Information** to open a separate window of the same name containing this information:

- Select **Acknowledgments** to show information about third-party software components, including license notices required by the software component authors. Then click **Show Information**.
- Select **License agreement** to show the COMSOL Multiphysics software license agreement. Then click **Show Information**.
- Select **Licensed products** to show the licensed COMSOL products, including the number of used licenses and the total number of licenses for each product. Then click **Show Information**.
- Select **Patents** to show the patents that the COMSOL software products are protected by. Then click **Show Information**.
- Select **System information** to show a list of system properties, which can be useful for troubleshooting purposes, for example. Then click **Show Information**.
- Click **COMSOL Web Page** to open your web browser on the main COMSOL web page.

You can also get information about the licensed products from the **Licensed and Used Products in Session** window.

[The Root Settings and Properties Windows](#)

Checking for Product Software Updates

COMSOL provides product software updates that improve the software and correct any issues found.

To check if a product update is available, from the **File** menu select **Help>Check for Product Updates** ().

The program then checks if an update that is applicable, but not yet installed, is available from the COMSOL website.

If an update is available, an **Update** dialog box appears; click **Download** to download the update directly, or click **Browse Update** to open the COMSOL website where you can read about and download the update.

If no updates are available, the **Update** dialog box reports that your COMSOL installation is up to date. Open [The Preferences Dialog Box](#) and click **Updates** to select the **Check for updates at launch** check box to make the program check for updates each time you launch the COMSOL Multiphysics program.

Typographical Conventions

All documentation uses a set of consistent typographical conventions that make it easier to follow the discussion, understand what you can expect to see on the graphical user interface (GUI), and know which data must be entered into various data-entry fields.

In particular, these conventions are used throughout the documentation:

CONVENTION	EXAMPLE
text highlighted in blue	Click text highlighted in blue to go to other information in the PDF. When you are using the help desk in COMSOL, links to other modules, application examples, and documentation sets also work.
boldface font	A boldface font indicates that the given word(s) appear exactly that way on the COMSOL Desktop (or, for toolbar buttons, in the corresponding tooltip). For example, the Model Builder window is often referred to, and this is the window that contains the model tree. As another example, the instructions might say to click the Zoom Extents button (⊕), and this means that when you hover over the button with your mouse, the same label displays on the COMSOL Desktop.
<i>italic</i> font	An <i>italic</i> font is the introduction of important terminology. Expect to find an explanation in the same paragraph or in the Glossary. The names of other documents in the COMSOL documentation set are also in <i>italic</i> font.
Forward arrow symbol >	The forward arrow symbol > means you select a series of menu items or nodes in a specific order. For example, Component>Mesh is equivalent to: Under the Component node, click the Mesh node.
code (monospace) font	A code (monospace) font means you make a keyboard entry in the COMSOL Desktop. You might see an instruction such as “Enter (or type) 1.25 in the Current density field.” The monospace font is also used to indicate programming code and variable names.
Italic code (monospace) font	An italic code (monospace) font indicates user inputs and parts of names that can vary or be defined by the user.
Arrow brackets <> following the code (monospace) or code (italic) fonts	The arrow brackets included in, for example, programming examples (after a monospace code or an italic code font) mean that the content in the string can be freely chosen or entered by the user, such as a feature Name or Label. For example, <code>model.geom(<label>)</code> , where <label> is the geometry's label. When the string is predefined by COMSOL Multiphysics, no bracket is used and this indicates that this is a finite set, such as a feature type.

KEY TO THE GRAPHICS

Throughout the documentation, icons are used to help organize the information. These icons vary in importance, but it is recommended that you read these text boxes.

ICON	NAME	DESCRIPTION
	Caution	A Caution icon indicates that the user should proceed carefully and consider the next steps. It might mean that an action is required, or if the instructions are not followed, that there will be problems with the model solution.
	Important	An Important icon indicates that the information provided is key to the model building, design, or solution. The information is of higher importance than a note or tip, and the user should endeavor to follow the instructions.
	Note	A Note icon indicates that the information can be of use to the user. It is recommended that the user reads the text.
	Tip	A Tip icon is used to provide information, reminders, shortcuts, suggestions for improving model design, and other information that might be useful.
	See Also	The See Also icon indicates that other useful information is located in the named section. If you are working online, click the hyperlink to go to the information directly. When the link is outside of the current PDF document, the text indicates this, for example, “See The Laminar Flow Interface in the <i>COMSOL Multiphysics Reference Manual</i> .” Note that if you are in the online help, the link works.

ICON	NAME	DESCRIPTION
	An example from the Application Libraries	The icon is used in the documentation to indicate examples that demonstrate the use of some functionality. In some cases, an example is only available if you have a license for a specific module. The Application Library path describes how to find the actual file in COMSOL Multiphysics, for example: If you have the RF Module, see <i>Radar Cross Section: Application Library path RF_Module/Scattering_and_RCS/radar_cross_section</i>
	Space Dimension	Another set of icons is used in the Model Builder — the component space dimension is indicated by 1D axial symmetry , 2D , 2D axial symmetry , and 3D icons. The 1D and 0D icons are not used but the space dimension is indicated. These icons are also used in the documentation to list the differences to a physics interface, node, or theory section, which are based on space dimension.
	Windows	This icon means that the information is specific to a Microsoft Windows operating system.
	macOS	This icon means that the information is specific to a macOS operating system. This may also be referred to as cross-platform when describing how to access a feature or menu on the COMSOL Desktop.
	Linux	This icon means that the information is specific to a Linux operating system. This may also be referred to as cross-platform when describing how to access a feature or menu on the COMSOL Desktop.

Overview of the Reference Manual

This *COMSOL Multiphysics Reference Manual* provides comprehensive information about all modeling steps using the COMSOL Multiphysics software. See the individual module manuals for information specific to a specialized module (see [The COMSOL Multiphysics Modules and Interfacing Options](#) for a link to the COMSOL website).

As detailed in the section [COMSOL Documentation and Help](#) this information can also be searched from the [Help](#) system in COMSOL Multiphysics.

TABLE OF CONTENTS, GLOSSARY, AND INDEX

To help you navigate through this guide, see the [Contents](#), [Glossary](#), and [Index](#).

ENVIRONMENT

The [COMSOL Modeling Environment](#) chapter provides an overview of the COMSOL modeling environment as controlled by the COMSOL Desktop and the tools and windows it provides in the Windows version as well as the cross-platform version. Topics include [The COMSOL Desktop](#), [The Application Libraries Window](#), [The Physics Interfaces](#), [Creating a New Model](#) with the Model Wizard, and a key to the icons including links in the [Toolbars](#) and [Keyboard Shortcuts](#) section.

MODELING

[Building a COMSOL Multiphysics Model](#) explains a range of methods and topics including information about the following: details about an introduction to [The Model Builder](#), [The Component Node](#), [The Physics Nodes](#), [Selecting Physics Interfaces](#), [Analyzing Model Convergence and Accuracy](#), [Specifying Model Equation Settings](#), [Boundary Conditions](#), [Using Units](#), [Numerical Stabilization](#), and much more.

CUSTOMIZING THE COMSOL DESKTOP

In the [Customizing the COMSOL Desktop](#) chapter, the settings are described related to [Customizing a Model](#), changing [Preferences Settings](#), and details about the [Advanced Physics](#), [Study](#), and [Results Sections](#).

DEFINITIONS

The [Global and Local Definitions](#) chapter describes the global and local (component) definitions features. Depending on the geometric scope, you add the nodes described in this section to either the Global Definitions node or under the Definitions node for a particular component. Topics include [Operators](#), [Functions](#), and [Constants](#), [Predefined and Built-In Variables](#), [Mass Properties](#), [Functions](#), [Component Couplings and Coupling Operators](#), [Coordinate Systems](#), [Identity and Contact Pairs](#), [Probes](#), and [Infinite Elements](#), [Perfectly Matched Layers](#), and [Absorbing Layers](#).

VISUALIZATION AND SELECTION

The [Visualization and Selection Tools](#) chapter describes the tools used to visualize and control how you view models and select parts of the model geometry in the Graphics window and the Settings windows. Important topics include [Working with Geometric Entities](#), [Creating Named Selections](#), and [User-Defined Views](#).

GEOMETRY

The [Geometry Modeling and CAD Tools](#) chapter covers geometry modeling in 1D, 2D, and 3D with examples of solid modeling, boundary modeling, Boolean operators, and other CAD tools in COMSOL. In addition, it shows how to use the tools for exploring geometric properties, such as volumes and surfaces. There is also information

about using external CAD data. Topics include [Creating a Geometry for Analysis](#), [Working with Geometry Sequences](#), [Geometric Primitives](#), [Geometry Operations](#), and [Virtual Geometry and Mesh Control Operations](#).

MESH

The [Meshing](#) chapter summarizes how to create and control your mesh for 1D, 2D, and 3D geometries in the COMSOL Multiphysics software. It also explains these topics, which include: [Creating a Mesh for Analysis](#), [Meshing Techniques](#), [Meshing Operations and Attributes](#), and [Importing and Exporting Meshes](#).

MATERIAL

The [Materials](#) chapter introduces you to the material databases included with the COMSOL products. Topics include a [Materials Overview](#), [Working with Materials](#), [Material Properties Reference](#), [User-Defined Materials](#) and [Libraries](#), [Using Functions in Materials](#), and [Module-Specific Material Databases](#).

AC/DC

The [AC/DC Interfaces](#) chapter explains the physics interfaces available for modeling electromagnetics, which you find under the AC/DC branch () when adding a physics interface. It also contains sections about general fundamentals and theory for electric fields.

ACOUSTICS

The [Pressure Acoustics Interface](#) chapter describes how to use the Pressure Acoustics, Frequency Domain interface, found under the Acoustics branch () when adding a physics interface, for modeling and simulation of acoustics and vibrations.

CHEMICAL SPECIES TRANSPORT

The [Chemical Species Transport Interfaces](#) chapter explains how to use the Transport of Diluted Species interface, found under the Chemical Species Transport branch () when adding a physics interface, to model and simulate mass transfer by diffusion and convection based on Fick's law of diffusion.

FLUID FLOW

The [Fluid Flow Interface](#) chapter explains how to use the Laminar Flow interface, found under the Fluid Flow>Single-Phase Flow branch () when adding a physics interface, to model and simulate fluid mechanics for laminar, incompressible fluids.

HEAT TRANSFER

The [Heat Transfer Interfaces](#) chapter describes the different types of Heat Transfer interfaces (Heat Transfer in Solids and Heat Transfer in Fluids), and the Joule Heating interface, all found under the Heat Transfer branch () when adding a physics interface.

SOLID MECHANICS

The [Solid Mechanics](#) chapter explains how to use the Solid Mechanics interface, found under the Structural Mechanics branch () when adding a physics interface, to simulate and analyze applications involving solid mechanics. The physics interface is used for stress analysis and general solid mechanics simulation.

EQUATION-BASED MODELING

The [Equation-Based Modeling](#) chapter describes the use of the mathematics interfaces, found under the Mathematics branch () when adding a physics interface, which are used for equation-based modeling. With those interfaces you can solve various types of PDEs using different formulations. You can also solve ODEs and other global equations, add events and curvilinear coordinates, compute sensitivities, and add moving interfaces and deforming meshes.

SENSITIVITY ANALYSIS

The [Sensitivity Analysis](#) chapter describes how to perform sensitivity analysis using the Sensitivity interface, found under the Mathematics>Optimization and Sensitivity () branch when adding a physics interface.

DEFORMED MESHES

The [Deformed Geometry and Moving Mesh](#) chapter explains how to use the modeling physics interfaces that control mesh deformation. These are found under the **Mathematics>Deformed Mesh** () branch when adding a physics interface. It also contains fundamentals about deformed meshes and information about the Eulerian and Lagrangian formulations of the physics, the frame types that support these formulations, and the arbitrary Lagrangian-Eulerian (ALE) method.

STUDIES AND SOLVERS

The [Studies and Solvers](#) chapter lists the various types of solvers and studies in the COMSOL Multiphysics software and explains the study steps and solver configurations. It also describes the major solvers and settings as well as batch jobs, parametric sweeps, and cluster computing. See also the *Optimization Module Manual* for other supplementary information.

RESULTS AND VISUALIZATION

The [Results Analysis and Plots](#) chapter helps you analyze results in COMSOL Multiphysics and describes numerous result-evaluation and visualization tools, including advanced graphics, data display, and export functions. Topics include [Results Overview](#), [Data Sets](#), [Plot Groups and Plots](#), [Derived Values](#), [Evaluation Groups](#), and [Tables](#), [Exporting Data and Images](#), [Reports](#), and [Printing and Capturing Screenshots](#).

RUNNING COMSOL MULTIPHYSICS

[Running COMSOL Multiphysics](#) is an overview of the different ways that you can run the COMSOL Multiphysics software in addition to running the COMSOL Desktop on a dedicated computer, including client-server and distributed-memory architectures and cloud-based computing.

The COMSOL Modeling Environment

The COMSOL Desktop® provides a complete and integrated modeling environment for creating, analyzing, and visualizing multiphysics models. This chapter provides an overview of the COMSOL Multiphysics® modeling environment as controlled by the COMSOL Desktop and the tools and windows it provides.

In this chapter:

- [The COMSOL Desktop](#)
- [The Application Libraries Window](#)
- [The Physics Interfaces](#)
- [Creating a New Model](#)
- [Toolbars and Keyboard Shortcuts](#)

The COMSOL Desktop

This section is an overview of the major components in the COMSOL Multiphysics environment. These components are integrated into the *COMSOL Desktop*, which you can personalize to your own modeling needs and preferences. Primarily consisting of the *Model Builder* nodes, *Settings* windows, and *Graphics* windows, other dockable windows can be opened, closed, and organized according to the modeling settings you need to access and the GUI configuration you want to work in. You can save these configurations, and the last opened configuration is always displayed when you open COMSOL again.

- [Creating a New Model](#)
- [Building a COMSOL Multiphysics Model](#)
- [Customizing the COMSOL Desktop](#)
- [The Model Builder](#)

The COMSOL Desktop in the cross-platform version, primarily for the Linux and macOS operating systems, looks slightly different than for the Windows operating system (shown in [Figure 2-1](#)). The primary difference is that the Main Menu and Main Toolbar are used instead of ribbons. Otherwise, the default windows (Model Builder, Graphics, Settings, Log, Progress, and Messages) are in the same location on the default desktop layout. See [The COMSOL Desktop Menus and Toolbars](#) for more details.

You can also launch the cross-platform version on Windows using `comsolxpl.exe`.

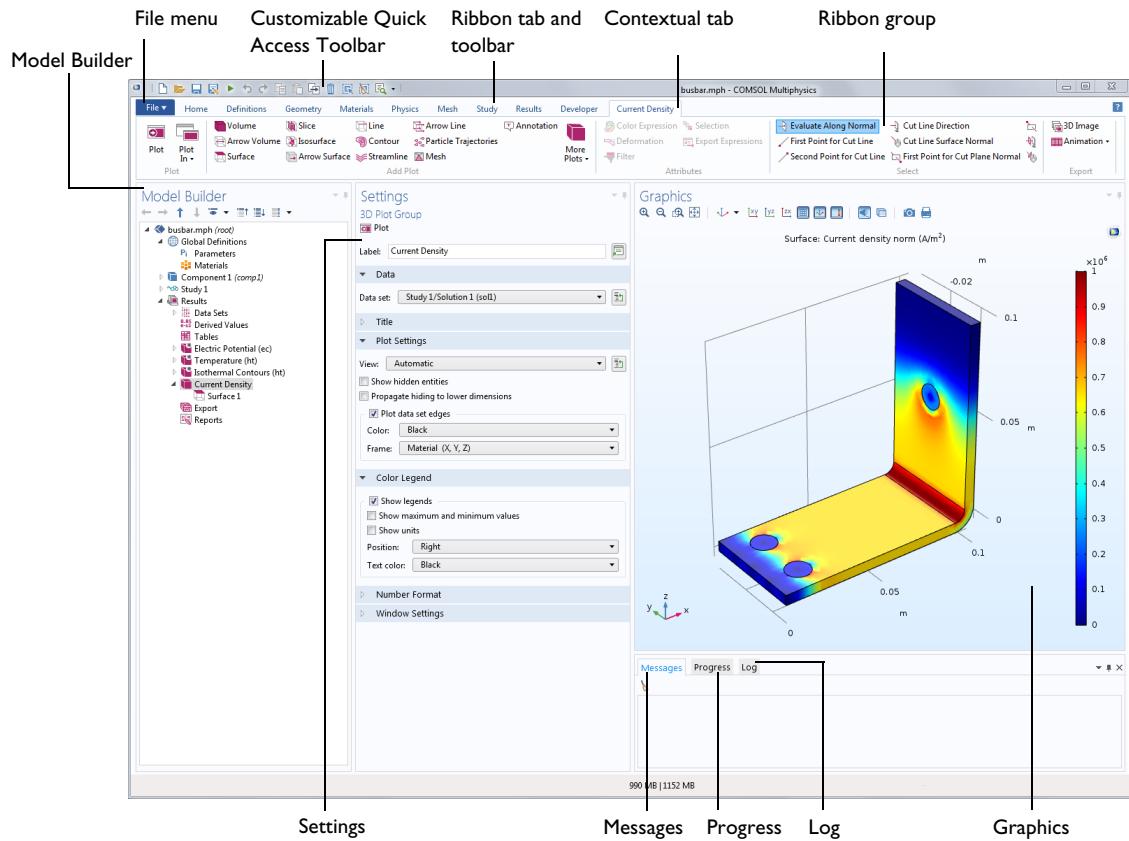

Figure 2-1: The default COMSOL Desktop with its major windows in a widescreen layout. The ribbon tabs and groups are available for Windows users. For macOS and Linux users the layout is similar but you access some options from the main menu or contextual toolbars.

Win

A ribbon tab, ribbon group, or modal ribbon tab, are available in the Windows version. In general, these are referred to as *toolbars*. See [Figure 2-1](#) for an example of the Windows **Home** toolbar. Also see [Figure 2-2](#) for an example of how the ribbon changes when a window is resized.

Mac

Linux

The *Model Toolbar* and *Contextual Toolbar* are available in the cross-platform version, primarily for macOS and Linux users. See [Figure 2-11](#) for an example of these toolbars.

ABOUT CHANGES TO THE RIBBON DISPLAY (WINDOWS USERS)

When the complete COMSOL Desktop is resized, the toolbar collapses and the buttons are grouped into menus. In Figure 2-2, all the groups in the **Home** toolbar are collapsed into menus. As the window is widened, the ribbon groups expand again to include the options as buttons or other submenus.

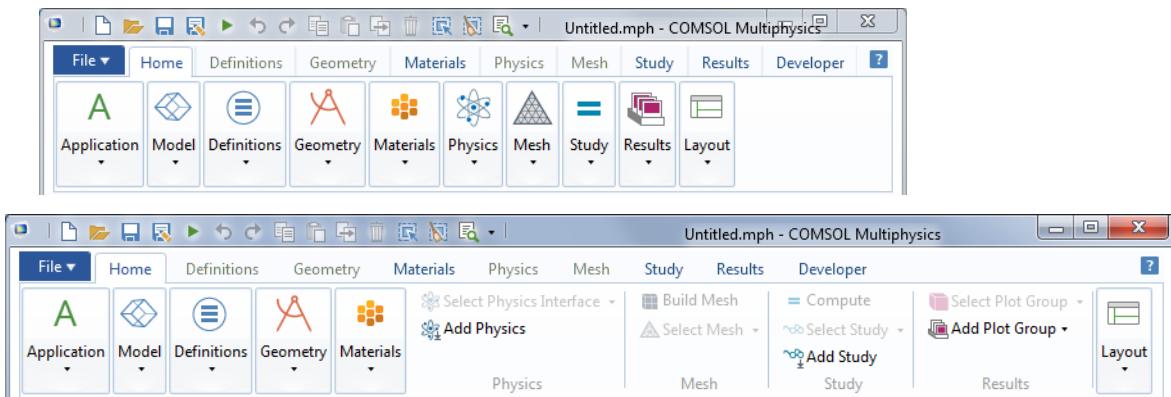

Figure 2-2: When the COMSOL Desktop is resized, the ribbon toolbar buttons are grouped together with the ribbon tab group name. In this example for the **Home** toolbar, all the buttons are available from a menu, such as **Definitions**, **Geometry**, **Material**, **Physics**, and so forth (top). As the window is widened, the menus expand accordingly (bottom).

OPENING THE APPLICATION BUILDER FROM THE COMSOL DESKTOP

When you are on the COMSOL Desktop you can toggle between the Application Builder and COMSOL Multiphysics. In the **Home** toolbar click **Application Builder**  to open the Application Editor and modify the user interface of the application and to create and edit code for the application. You can also press **Ctrl+Alt+A**.

Conversely, when you are in the Application Builder, you can click **Model Builder**  in the **Home** toolbar to return to COMSOL Multiphysics. You can also press **Ctrl+Alt+M**.

OVERVIEW

The rest of this section introduces you to the features of the COMSOL Desktop, explains some basic navigation, and provides you with an overview of the windows, toolbars, and menus available. In this chapter you will also learn about the model file formats, the options to save files, and the units systems available for modeling.

- [Basic Navigation](#)
- [Adjusting Window Location and Size on the Desktop](#)
- [The COMSOL Desktop Windows](#)
- [The COMSOL Desktop Menus and Toolbars](#)
- [Windows Toolbars and Menus](#)
- [Cross Platform \(macOS and Linux\) Toolbars and Menus](#)
- [Features Available on Toolbars and From Menus](#)
- [The Messages Window](#)
- [About the COMSOL Model File Formats](#)
- [Saving COMSOL Files](#)
- [Saving and Opening Recovery Files](#)
- [The Root Settings and Properties Windows](#)
- [Unit Systems](#)

After this introductory overview, [The Application Libraries Window](#) section explains how to work with the application libraries included with the COMSOL Multiphysics products. [The Physics Interfaces](#) section lists the interfaces available with a basic COMSOL Multiphysics license. This prepares you to start creating a new model.

The next section, [Creating a New Model](#), shows you how to use the Model Wizard to begin building a new model by choosing a physics interface and study combination.

The last section, [Toolbars and Keyboard Shortcuts](#), is a quick reference to all the features found on the toolbars. It includes links to the information contained throughout this reference manual.

Basic Navigation

Basic navigation on the COMSOL Desktop extensively involves the nodes in the Model Builder as well as moving between windows and sections on **Settings** windows.

WORKING WITH NODES IN THE MODEL BUILDER

The following methods are available to select nodes, expand and collapse branches, open the **Settings** window, or move up and down the nodes in the model tree:

- Click a node in the Model Builder to highlight it and to open the associated **Settings** window. See [Settings and Properties Windows for Feature Nodes](#). You can also adjust how you are [Displaying Node Names, Tags, and Types in the Model Builder](#).
- Once a node is highlighted, there are many things you can do; for example, you can copy, duplicate, delete, and move most nodes around. See [Copying, Pasting, and Duplicating Nodes](#), [Moving Nodes in the Model Builder](#), and [Clearing Sequences and Deleting Sequences or Nodes](#).
- Right-click a node to open a context menu. See [Opening Context Menus and Adding Nodes](#).
- Group related nodes together, for better overview and structure for the model tree. See [Custom Grouping of Nodes](#).
- When a node is highlighted, use the up arrow key on the keyboard to move to the node above; to move to the node below, use the down arrow key.
- To expand a branch to display all nodes in the branch, click the small left-pointing white triangle next to the branch icon in the model tree, or press the right arrow key. To collapse a branch to display only the main branch node, click the small downward-right pointing black triangle next to the branch icon in the model tree, or press the left arrow key. See [The Model Builder Toolbar](#) for information about how to collapse or expand all branches.
- A highlighted node is also dynamic and its appearance can change based on where in the modeling process you are. See [Dynamic Nodes in the Model Builder](#) for a list of these visual cues.

[The COMSOL Desktop Menus and Toolbars](#)

MOVING BETWEEN WINDOWS AND SECTIONS ON THE COMSOL DESKTOP

Keyboard shortcuts are quick ways to navigate between the windows on the COMSOL Desktop and to switch focus between windows and **Settings** window sections:

- Press Ctrl+Tab to switch focus to the next window on the desktop.
- Press Ctrl+Shift+Tab to switch focus to the previous window in the desktop.
- Press Ctrl+Alt+left arrow to switch focus to the **Model Builder** window.
- Press Ctrl+Alt+right arrow to switch focus to the **Settings** window.

- Press Ctrl+Alt+up arrow to switch focus to the previous section in the **Settings** window.
 - Press Ctrl+Alt+down arrow to switch focus to the next section in the **Settings** window.
-

The section [Keyboard Shortcuts](#) lists additional shortcuts for all operating systems.

- [The COMSOL Desktop](#)
 - [The Model Builder](#)
 - [Creating a New Model](#)
-

Adjusting Window Location and Size on the Desktop

MOVING AND RESIZING THE WINDOW

- To move a window, click-and-drag the window tab (the tab is where the window name displays, **Model Builder** for example) to where you want it.
 - To resize a window, hover your mouse over the window borders until a double arrow displays. Click-and-drag the borders between windows until the layout appears as you want it to be.
-

At any time, in the **Home** toolbar, **Layout** group, click the **Reset desktop** button.

CLOSING A WINDOW

Not all windows in the COMSOL Desktop are closable. Windows that you can close have an **X** to the right of the window tab. Click that **X**, right-click the window and choose **Close**, or press Ctrl+F4 (Command+W on macOS). You can reopen a closed window by choosing it from the **Windows** menu (on the **Home** toolbar in the Windows® version), for the **Properties** and **Statistics** window, by right-clicking a node and choosing **Properties** or **Statistics** (for mesh statistics), respectively.

Figure 2-3: Click the X to close the **Properties** window. The **Settings** window cannot be closed.

FLOATING/DETACHING A WINDOW

Win

To detach a window to move and resize it, right-click the window tab and select **Float**. Right-click the window and choose **Dock** to return it to its default location on the Desktop.

Mac

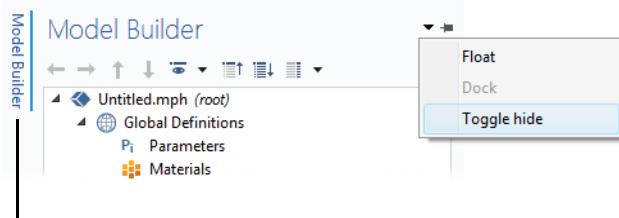

To detach a window to move and resize it, right-click the window tab and select **Detached**. Right-click and select the option again to dock it to the COMSOL Desktop, or drag and drop it back to where you want it.

Linux

HIDING OR PINNING A WINDOW TO THE SIDE OF THE DESKTOP (WINDOWS USERS)

To hide a window, right-click the window and select **Hide**. The window is minimized along the side of the Desktop (see [Figure 2-4](#)). Hover over the name to view a hidden/minimized window. To restore a hidden window, either right-click the window, or from the list, select **Float** or **Dock**.

Pinning a window performs the same action as hiding it. Click the **Toggle hide** button  in the top-right corner of any window to hide and pin it to the side of the COMSOL Desktop. To return the window to its unhidden state, hover over the window name to open it, then click the **Toggle hide** button (now laying on its side, see [Figure 2-4](#)) to restore the window to its default location.

When you hide a window, it is minimized along the side of the Desktop. Hover over the name to view the window.

Figure 2-4: A hidden window is minimized along the side of the Desktop. Hover over the window name to view it. You can then choose to Float or Dock the window (either right-click the window or choose options from the menu), or click the Toggle hide icon to restore it to the default location on the Desktop.

USING THE POSITION GUIDES (WINDOWS USERS)

When customizing your COMSOL Desktop, or when you want to return a floating window to the Desktop (Dock it), there are several visual guides available to assist.

Click and hold the mouse on a window to reposition or dock it on the Desktop. This displays the positioning guides ([Figure 2-5](#) and [Figure 2-6](#)). Drag the window over any of the guides to highlight the area where the window is to be placed on the desktop ([Figure 2-6](#)). The center guide has five options. There are two vertical positioning guides,

one on the left and one on the right of the Desktop and two horizontal positioning guides, one on the top and one on the bottom of the Desktop.

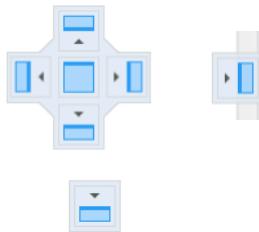

Figure 2-5: Examples of the positioning guides.

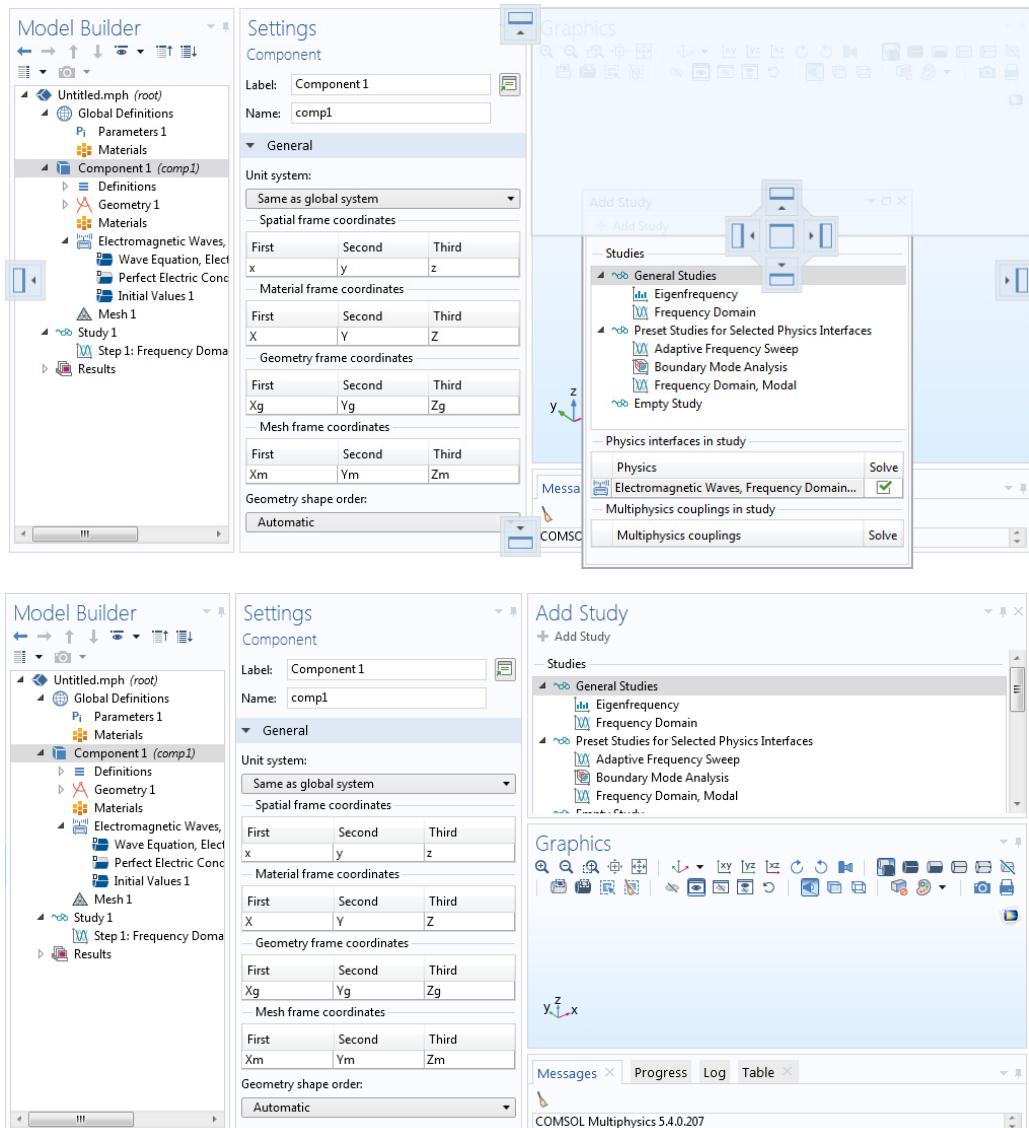

Figure 2-6: The positioning guides display (top image) when you click and hold the mouse pointer on a window. Drag the window over any of the guides to see the highlighted light blue area, which indicates the destination for the window. Release the mouse button and the window drops into place (bottom image).

RESIZABLE TABLES AND TEXT AREAS (WINDOWS USERS)

Some tables and text areas are resizable so that you can drag the area to extend it if it contains a lot of text. A border that you can drag to resize a table or text area is indicated by a thicker line:

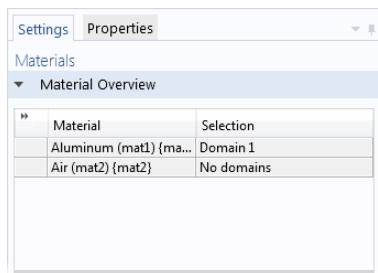

Figure 2-7: You can click and drag the thicker bottom border to resize the Material Overview table.

You can also click on the **>>** button in the top-left corner to expand the table to show its contents. If you click at the border between two columns in a table, you can then drag to resize the column to the left of the border, or double-click to resize that column to fit its contents.

SELECTING, COPYING, AND PASTING IN TABLES

In tables of parameters or variables, for example, you can select a row by clicking in one of the cells, and you can select multiple rows by Shift-clicking to select a range of rows or Ctrl-clicking to select a deselect a single row. Pressing **Ctrl+A** when you are editing a cell selects all text in the cell. If you are not editing a cell, the pressing **Ctrl+A** select the entire table. You can right-click selected rows in a table and choose **Select All**.

You can also right-click to **Cut**, **Copy**, and **Paste** the selected table rows. Alternatively, you can use the corresponding keyboard shortcuts **Ctrl+X**, **Ctrl+C**, and **Ctrl+V**, respectively.

MOVING, MINIMIZING, AND MAXIMIZING WINDOWS (MACOS AND LINUX)

- Right-click the window tab and select **Move>View** (to move a separate window). Move the mouse to where you want the window to display and left-click to confirm the move.
- Right-click the window tab and select **Move>Tab Group** (to move several tabbed windows) from the list. Move the mouse to where you want to the group of windows to display and left-click to confirm the move.
- To resize a window, hover the mouse over the left, right, top, or bottom boundaries of the window until a double arrow displays. Drag the mouse to resize the window. Or right-click the window tab and select **Size>Left**, **Right**, **Top**, or **Bottom**. A blue line highlights the choice; drag to resize.
- To maximize and restore a window's original position, double-click a window tab to maximize it; double-click again to restore it.
- Click the **Minimize** or **Maximize** button in the top-right corner or right-click the window tab and select **Minimize** or **Maximize** from the list.

At any time, click the **Reset desktop**  button in the main toolbar. The section [Keyboard Shortcuts](#) has additional shortcuts for all operating systems.

VERTICAL OR HORIZONTAL WINDOW ORIENTATION (MACOS AND LINUX)

After a window is minimized along the side of the COMSOL Desktop, you also have the option to change the window **Orientation** to **Vertical** (the default) or **Horizontal** when you click the window icon (see [Figure 2-8](#)).

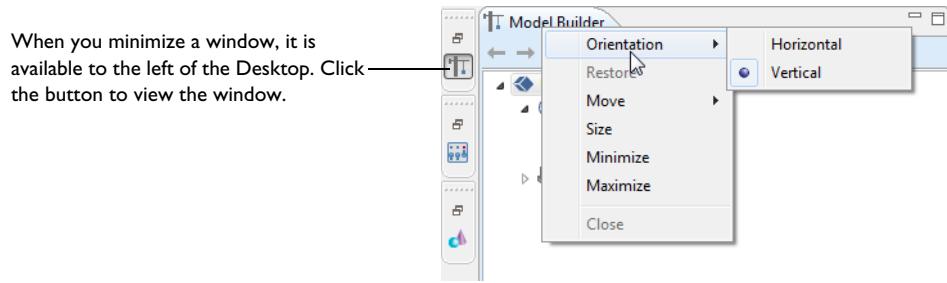

Figure 2-8: A minimized window is accessible to the left of the Desktop. Click the window icon to view it. You can then right-click the window to Move, Size, Minimize or Maximize the window. You can also change the Orientation of a minimized window to be Horizontal or Vertical when you click and view it on the Desktop in its minimized state.

- [The COMSOL Desktop](#)
- [The Model Builder](#)
- [Creating a New Model](#)

The COMSOL Desktop Windows

The COMSOL Desktop windows, including those shown in [Figure 2-1](#), are integral to building your model. The windows listed in [Table 2-1](#) are described throughout the documentation and the table includes links to this information. You can open windows that are currently not open in the COMSOL Desktop by choosing them from the **Windows** menu. The **Model Builder**, **Settings**, **Graphics**, and **Statistics** (for mesh statistics) windows cannot be closed and are therefore not available in the **Windows** menu.

TABLE 2-1: COMSOL DESKTOP WINDOWS

WINDOW NAME AND LINK	DESCRIPTION
BUILDING A MODEL	
The Model Wizard	Start building a model by choosing the Component space dimension, physics interfaces, and study.
The New window	Open the New window to begin modeling using the Model Wizard to start with a Blank Model. See Open a New Window to Begin Modeling .
The Model Builder	Control the modeling procedure using the model tree. This window has all the functionality and operations for building and solving models and displaying the results.
The Graphics Window	This window is a graphical view of the geometry, mesh, and results of the model. It also has useful tools to change the view and select multiple geometric entities, for example.
The Material Browser Window	Browse the material libraries and load materials into your models.
The Add Material Window	Add predefined materials.
Part Libraries	The Part Libraries contain collections of geometry parts, which serve as more advanced geometric primitives specially created for an application area.
The Add Physics Window	Add physics interfaces.
The Add Multiphysics Window	Add applicable multiphysics couplings.

TABLE 2-1: COMSOL DESKTOP WINDOWS

WINDOW NAME AND LINK	DESCRIPTION
The Settings and Properties windows	When a node is clicked in the Model Builder a corresponding Settings window opens with the same name as the node. It is a window with settings that define operations and properties specific to that node. The Properties window is accessed from the context menu and displays other node properties. See Settings and Properties Windows for Feature Nodes .
The Selection List Window	Choose objects, for example, while working with complex geometries and when you need to easily locate a geometric entity that is not easily viewed.
The Message window for geometry measurements	A tool used to measure geometry objects and entities. See Measuring Geometry Objects .
The Find Results window	Displays search results from searches performed using the Find tool. See Searching and Finding Text .
The Recovery Files window	Displays any existing recovery files and provides tools for opening, saving, and deleting recovery files. See Saving and Opening Recovery Files .
RESULTS AND ANALYSIS	
The Add Study Window	Add a study or studies to models.
The Plot Windows	Plot windows are also graphics windows. These plot windows display convergence results and monitor probe values while solving, for example.
The Table window	Displays the results from integral and variable evaluations defined in Derived Values nodes or by Probes and stored in Table nodes. It also displays results from nodes under an Evaluation Group node. See The Table Window and Tables Node .
The Messages Window	Contains information useful after an operation is performed.
The Progress Window	Displays the progress of the solver or mesher during the process, including a progress bar and progress information for each solver or mesher.
The Log Window	Contains information from previous solver runs, including convergence information, solution time, and memory use.
The Debug Log window	Contains debug information for model methods. See the Application Builder documentation for more information about debugging methods.
The External Process Window	Follow external processes (such as distributed batch jobs) that have been started. The window updates when you are attached to the external processes.
The Mesh Statistics Window	This window includes information about the minimum and average mesh element quality and a mesh element quality histogram, which shows the relative frequency of mesh elements with different quality values.
Comparing Models and Applications	This window includes the resulting differences from a comparison of models or applications.
APPLICATION EXAMPLES	
The Application Libraries Window	Displays all the models and applications included with an installation. The folders contain models and applications specific to the installed module.
The Application Library Update Window	A service that provides new and updated models and applications for each of the application libraries of the COMSOL products that your license includes.
HELP AND DOCUMENTATION	
The Help Window and Topic-Based Help	Provides access to context help in the COMSOL Desktop.
The Documentation Window	Navigate to PDF or HTML versions of the documentation (availability is based on your license), as well as Search, Bookmark, Print Topics, and Link with Contents.
The Root Settings and Properties Windows	The Root node is the topmost level of the Model Builder tree. When you click this node, the Root window opens and includes detailed information about the model file.

- [Creating a New Model](#)
- [The COMSOL Desktop](#)
- [COMSOL Documentation and Help](#)
- [Toolbars and Keyboard Shortcuts](#)

The COMSOL Desktop Menus and Toolbars

The menus and toolbars available from the COMSOL Desktop vary slightly between operating systems. However, the variations are subtle and the overall functionality remains the same.

The sections [Windows Toolbars and Menus](#) and [Cross Platform \(macOS and Linux\) Toolbars and Menus](#) show examples of the main terms and locations of the toolbars and menus.

The Model Builder toolbar is the same for all platforms and is described in this section.

The [Features Available on Toolbars and From Menus](#) section details the available features and functions.

THE MODEL BUILDER TOOLBAR

The Model Builder toolbar is the same for all operating systems. It is located at the top of the window as shown in [Figure 2-9](#). The actions listed in [Table 2-2](#) are used to navigate the Model Builder tree.

Figure 2-9: The Model Builder toolbar for Windows (left) and macOS and Linux (right).

- [The COMSOL Desktop](#)
- [Creating a New Model](#)
- The [Toolbars and Keyboard Shortcuts](#) section has detailed information about the contextual toolbars available on the COMSOL Desktop.

Windows Toolbars and Menus

The available ribbon toolbar options are dynamic, based on where in the model you are working and what is logically available for a specific task. When a blank model is created, only the default tabs are included (Model, Definitions, Study, and Results). The Physics, Geometry, and Mesh tabs are added once a model and physics interface are added to the Model Wizard, as shown in [Figure 2-10](#).

The top of the COMSOL Desktop includes a customizable Quick Access Toolbar. Underneath this are ribbon tabs and ribbon groups, which together, are referred to as *toolbars*. The **Home** toolbar is a collection of frequently used features from all the other toolbars. For documentation purposes, a toolbar uses the same name as the tab. For

example, the **Home** toolbar, **Physics** toolbar, **Geometry** toolbar, or **Study** toolbar. See [The Model Builder Toolbar and Features Available on Toolbars and From Menus](#) for a detailed list of all the features available.

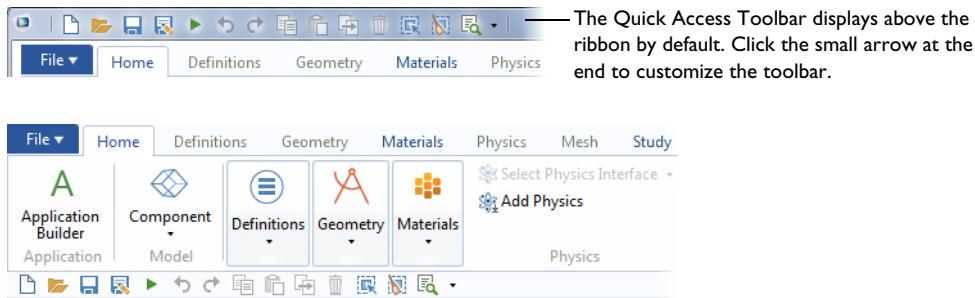

Figure 2-10: The Quick Access Toolbar can be positioned above or below the ribbons. You can also customize the toolbar to include or exclude a variety of buttons.

CUSTOMIZE THE QUICK ACCESS TOOLBAR

The Quick Access Toolbar has several default buttons that can be displayed above or below the ribbon. Click the small arrow at the end of the toolbar to open the **Customize the Quick Access Toolbar** list. You can either edit which of the default buttons display directly from the list, or click **More Commands** to **Add** and **Remove** (or double-click to add or remove) the buttons as detailed in the section [Features Available on Toolbars and From Menus](#). This can also be done in [The Preferences Dialog Box](#) in the **Quick Access Toolbar** section.

DISPLAY THE QUICK ACCESS TOOLBAR ABOVE OR BELOW THE RIBBON

Right-click a ribbon to select **Show Quick Access Toolbar Above the Ribbon** or **Show Quick Access Toolbar Below the Ribbon**. These options are also available from the Customize Quick Access Toolbar menu. See [Figure 2-10](#).

Select **Minimize the Ribbon**. To restore the ribbon, right-click anywhere in the top of the window and click **Minimize the Ribbon** to deactivate it (remove the check mark).

MINIMIZE (HIDE) THE RIBBON

Right-click anywhere on a ribbon and choose **Minimize the Ribbon** to hide the ribbon on the Desktop. To access the ribbon features, click the ribbon tab name (for example, **Model**, **Definitions**, or **Study**). The ribbon features are then available. To restore the ribbon to the top of the Desktop, right-click in the tab name area and click to remove the check mark next to **Minimize the Ribbon**.

Cross Platform (macOS and Linux) Toolbars and Menus

For cross-platform users (primarily macOS and Linux), the **Main Toolbar** is similar to the Quick Access Toolbar for Windows. In addition, there is a **Model Toolbar** and a variety of **Contextual Toolbars** available. These are a mixture of drop-down menus and buttons for frequently used actions. For documentation purposes, a toolbar uses the same name as the contextual toolbar. For example, the **Physics** toolbar, **Geometry** toolbar, or **Study** toolbar. See [The Model Builder Toolbar and Features Available on Toolbars and From Menus](#) for a detailed list of all the features available.

The Contextual Toolbar changes when you click a **Definitions**, **Geometry**, **Mesh**, **Study**, or **Results** node in the **Model Builder**. The Model Toolbar and Contextual Toolbar are similar to the ribbon toolbars for a Windows operating system.

You can also launch the cross-platform version on Windows using `comsolxp1.exe`.

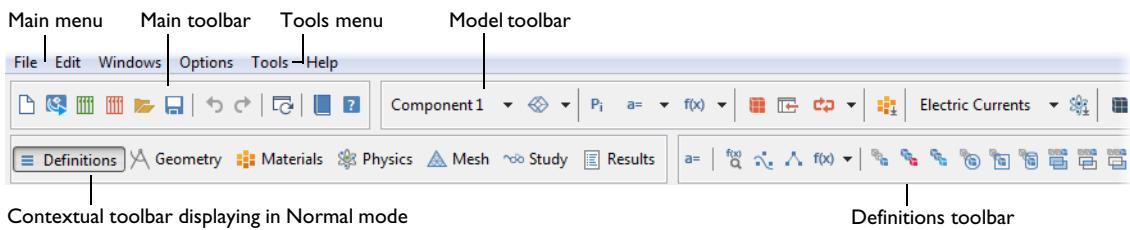

Figure 2-11: The menu and toolbar options for cross-platform users (usually macOS and Linux operating systems). Only part of the Model Toolbar and Contextual Toolbars are shown. When one of the buttons is clicked on this toolbar, the associated toolbar opens, in this example for the Definitions node. This toolbar also opens when the Definitions node is clicked in the Model Builder.

DISPLAY OR HIDE THE TOOLBARS FROM THE TOOLS MENU

From the **Tools** menu, you can choose to display or hide each toolbar. Select **Main Toolbar**, **Model Toolbar**, or **Contextual Toolbar** to turn that toolbar on or off in the COMSOL Desktop. For the **Toolbar Button Label**, you can also choose to **Show Icon Only** or **Show Icon and Text**. When **Show Icon and Text** is on it adjusts what is available on the toolbar as some buttons in the Model Toolbar display the text, while others have the label when you hover over the button. Finally, choose the **Toolbar Display Mode** as **Normal** or **Compact**. **Compact** compresses some buttons in the Contextual Toolbar and Model Toolbar under menus.

If you are using a **Regular Screen Layout** and want to view all available buttons, the optimal settings are to set the **Toolbar Button Label** to **Show Icon Only** and the **Toolbar Display Mode** to **Compact**.

OTHER USEFUL FUNCTIONS AVAILABLE FROM THE WINDOWS MENU

From the **Windows** menu there are also other useful functions:

- Open a variety of useful windows. See [The COMSOL Desktop Windows](#) for a list and links to applicable sections.
- From the **Model Builder Node Label** submenu, choose a way to label the nodes in the Model Builder. See [Displaying Node Names, Tags, and Types in the Model Builder](#).
- From the **Desktop Layout** submenu, choose a **Widescreen** or **Regular Screen** layout, or **Reset the Desktop**. See [Customizing the Desktop Layout](#).

Features Available on Toolbars and From Menus

The features listed in [Table 2-2](#) are often accessed from multiple locations. In general, the button or menu option is located as follows, with some minor differences between Windows and the cross-platform (macOS and Linux) systems and as described in [Windows Toolbars and Menus](#) and [Cross Platform \(macOS and Linux\) Toolbars and Menus](#).

- The **File** menu. See [Figure 2-10](#) (Windows) and [Figure 2-11](#) (macOS and Linux).
- The **Model Builder** toolbar. See [Figure 2-9](#).
- The **Quick Access Toolbar** (Windows only; see [Figure 2-10](#)). Customize the toolbar to access some of the buttons listed in the table.

- **Main Menu** and a **Main Toolbar** (macOS and Linux, see [Figure 2-11](#)).
- Additional menus along the top of the Desktop: **Edit**, **Windows**, **Options**, **Tools**, and **Help** (macOS and Linux, see [Figure 2-11](#)).

TABLE 2-2: FEATURES AVAILABLE ON VARIOUS TOOLBARS AND FROM MENUS

ICON	NAME	DESCRIPTION OR LINK TO MORE INFORMATION
Creating Models		
	New (Ctrl+N)	<p>Open the New window to begin modeling using the Model Wizard or start with a Blank Model. See Creating a New Model.</p> <p>For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users) or the Main Toolbar (cross-platform users).</p> <p>Additional options are available when check boxes are enabled on the Preferences dialog box under Physics Builder.</p>
	Blank Model	Start a new blank model without any settings. This command is available after choose File>New . It is also available on the Quick Access Toolbar (Windows users).
Working in the Application Builder		
	Application Builder (Ctrl+Alt+A)	Toggle between the Application Builder and COMSOL Multiphysics Model Builder windows. For Windows users this is available in the Home toolbar and the Developer toolbar.
	Data Access	Add data and properties that can be modified from a running application. For Windows users this is available in the Developer toolbar. See Data Access in the <i>Application Builder Reference Manual</i> .
	Record Method	Record changes to the embedded model to a new method. For Windows users this is available in the Developer toolbar. See Recording Code in the <i>Application Builder Reference Manual</i> .
	Test Application (Ctrl+F8)	Launch the application in a separate window. For Windows users this is available in the Developer toolbar and on the Quick Access Toolbar. See Testing the Application in the <i>Application Builder Reference Manual</i> .
	Run Application	Run an application as a standalone application using a custom user interface. For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users).
	Compiler	Compile an application to run separately from COMSOL Multiphysics or COMSOL Server as a standalone executable app. Requires a license for COMSOL Compiler.
Opening and Saving Files		
	Open (Ctrl+O)	<p>Open an existing file located on the computer.</p> <p>For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users) or the Main Toolbar (cross-platform users).</p>
	Recent files	<p>From the File menu, select a recent file to open. For Windows users, the file is selected from the Recent submenu. For cross-platform users, the most recent files are listed at the bottom of the list.</p> <p>Windows users can also customize the Quick Access Toolbar to access this button.</p>
	Find	<p>Displays search results from searches performed using the Find tool. Press Ctrl+F.</p> <p>Windows users can also customize the Quick Access Toolbar to access this button. See Searching and Finding Text.</p>

TABLE 2-2: FEATURES AVAILABLE ON VARIOUS TOOLBARS AND FROM MENUS

ICON	NAME	DESCRIPTION OR LINK TO MORE INFORMATION
	Application Libraries	<p>Open The Application Libraries Window.</p> <p>For Windows users, this is available in the Home toolbar's Windows menu or from the File menu. You can also customize the Quick Access Toolbar and then click the button.</p> <p>For cross-platform users, this is available from the File menu.</p>
	Open Recovery File	<p>COMSOL Multiphysics can store recovery files each time you start a solver. This is a preference setting that is initially active by default. For all users, this is available from the File menu. It is also available on a customized Quick Access Toolbar (Windows users).</p> <p>See Saving and Opening Recovery Files.</p>
	Save (Ctrl+S)	<p>Save the current file. For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users) or the Main Toolbar (cross-platform users).</p> <p>See Saving COMSOL Files.</p>
	Save As	<p>Choose to save in one of the COMSOL file formats. The Save As window opens, and from the Save as type list select: COMSOL Application (*.mph) (the default), Model file for Java (*.java), Model file for MATLAB (*.m), or Model File for Visual Basic (*.vba).</p> <p>For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users).</p> <p>See About the COMSOL Model File Formats.</p>
	Revert to Saved	<p>Opens the last saved version of the file and reinitializes the GUI. For all users, this is available from the File menu. It is also available on a customized Quick Access Toolbar (Windows users) or the Main Toolbar (cross-platform users).</p> <p>See Reverting to the Last Saved File.</p>
	Compact History	<p>The files for Java and for MATLAB contain the entire model history, including settings that are no longer part of the model or application. For all users, this is available from the File menu. It is also available on a customized Quick Access Toolbar (Windows users).</p> <p>See Compacting the History.</p>
	Run Application	<p>Run an application created using the Application Builder.</p> <p>For all users, this is available from the File menu. It is also available on the Quick Access Toolbar (Windows users) or the Main Toolbar (cross-platform users).</p>

COMSOL Multiphysics Server

	Connect to Server	<p>To connect to a server from the COMSOL Desktop. For all users, this is available from the File>COMSOL Multiphysics Server menu. It is also available on a customized Quick Access Toolbar (Windows users).</p> <p>See Connecting to a COMSOL Multiphysics Server.</p>
	Disconnect from Server	<p>To close the connection to the server or MATLAB. For all users, this is available from the File>COMSOL Multiphysics Server menu. It is also available on a customized Quick Access Toolbar (Windows users).</p> <p>See Disconnecting from a COMSOL Multiphysics Server.</p>
	Import Application from Server	<p>To import a particular application when working with MATLAB, Excel, or the COMSOL API. For all users, this is available from the File>COMSOL Multiphysics Server menu. It is also available on a customized Quick Access Toolbar (Windows users).</p> <p>See Working with MATLAB, Excel, or the COMSOL API.</p>

TABLE 2-2: FEATURES AVAILABLE ON VARIOUS TOOLBARS AND FROM MENUS

ICON	NAME	DESCRIPTION OR LINK TO MORE INFORMATION
	Remove Applications from Server	To delete applications (remove them from the server) that you have created using ModelUtil. For all users, this is available from the File>COMSOL Multiphysics Server menu. It is also available on a customized Quick Access Toolbar (Windows users). See Working with MATLAB, Excel, or the COMSOL API .
Model Builder Toolbar		
	Previous Node (Alt+Left)	Navigate back to the node previously selected or to the next node in the sequence. See also Keyboard Shortcuts .
	Next Node (Alt+Right)	
	Show	Click to select an option from the list. See Advanced Physics, Study, and Results Sections .
	Collapse All	Click to collapse or expand all nodes in the model tree, except the top nodes on the main branch.
	Expand All	
	Model Builder Node Label	Choose to display any combination of Name, Tag, or Type. See Displaying Node Names, Tags, and Types in the Model Builder and Settings and Properties Windows for Feature Nodes .
Undo, Redo, Copy, Paste, Duplicate, and Delete		
	Undo (Ctrl+Z)	Undo and Redo the last operation for some operations (such as adding, disabling, moving, and deleting nodes in the Model Builder) as well as changing values in the Settings window.
	Redo (Ctrl+Y)	For Windows users, this is available on the Quick Access Toolbar. For cross-platform users, this is available in the Main Toolbar or from the Edit menu. See Undoing and Redoing Operations .
	Copy	Copy, paste, and duplicate some features. Also right-click a node to select one of these options from the context menu.
	Paste	For Windows users, this is available on the Quick Access Toolbar. For cross-platform users, this is available in the Main Toolbar or from the Edit menu.
	Duplicate	See Copying, Pasting, and Duplicating Nodes .
	Delete (Del)	Delete some nodes while building a model, or delete a selected geometry object. Also press the Del key or right-click a node to select this option from the context menu. For Windows users, this is available on the Quick Access Toolbar. For cross-platform users, this is available in the Main Toolbar or from the Edit menu. See Clearing Sequences and Deleting Sequences or Nodes .
	Select All	To select all or clear the selection of all geometric entities in the Graphics window, click the Select All or Clear Selection buttons, respectively.
	Clear Selection	For Windows users, this is available on the Quick Access Toolbar. For cross-platform users, this is available from the Edit menu. See Selecting and Clearing Selection of Geometric Entities .

	About COMSOL Multiphysics	For Windows users, this is available from the File>Help menu. For cross-platform users, this is available from the Help menu. See The About COMSOL Multiphysics Box .

The Messages Window

The **Messages** window () displays by default and contains information useful to you after an operation is performed.

The information in this window includes:

- Details about opening and saving model files such as MPH-files.
- Information about geometry objects imported from CAD files.
- On the **Mesh** and **Geometry** toolbars, click the **Measure** () button to view information about:
 - The geometry finalization (forming a union or an assembly) and about the number of geometric entities (domains, boundaries, and so on) in the finalized geometry.
 - The number of mesh elements and degrees of freedom in the model.
- Solution times.
- Error messages. The messages are in chronological order and can be scrolled through.

By default, the messages are preceded by a timestamp, providing the current date and time for the message. To turn off the timestamps, open the **Preferences** dialog box and clear the **Add timestamps to messages** check box on the **General** page under **Log and messages**.

To open the **Messages** window:

- From the **Home** toolbar (Windows users) select **Windows>Messages**.
- From the main menu (macOS and Linux users) select **Windows>Messages**.
- To clear the window of all messages, click the **Clear** button ().

	<ul style="list-style-type: none"> • Meshing • Geometry Modeling and CAD Tools • Studies and Solvers
--	---

About the COMSOL Model File Formats

Below find a list of the COMSOL file formats: MPH-files for applications and models, model files for Java, model files for MATLAB, and model files for VBA.

THE ROOT NODE

When you first open or create a new model, the *Root node* (❶) is the topmost level of the tree. By default, unnamed files are called `Untitled.mph`. The filename changes when the file is saved for the first time, but the root node *Name* does not change for this top level node. See [The Root Settings and Properties Windows](#) for details about the settings available when this node is clicked.

COMSOL MPH-FILES

The default standard file format with the extension `.mph`. The files contain binary and text data. The mesh and solution data are stored as binary data, while all other information is stored as plain text.

You can quickly save and load MPH-files. All models and applications in the COMSOL Application Libraries in the modules are saved as MPH-files.

The MPH-files in the COMSOL Application Libraries can have two formats:

- *Solved MPH-files* include all meshes and solutions. In the **Application Libraries** window these files appear with the icon ❷. If the MPH-file's size exceeds 25MB, a tooltip with the text "Large file" and the file size appears when you position the cursor at the node in the **Application Libraries** tree.
- *Compact MPH-files* include all settings but have no built meshes and solution data to save space (a few compact MPH-files have no solutions for other reasons). You can open these to study the settings and to mesh and re-solve it. It is also possible to download the full versions — with meshes and solutions — of most of these through Application Library Update (see [The Application Library Update Window](#)). In the **Application Libraries** window these appear with the icon ❸. If you position the cursor at a compact file in the Application Libraries window, a **No solutions stored** message appears. If a full MPH-file is available for download, the corresponding node's context menu includes a **Download File With Solution** icon (❹).

File Locking

Only one user can open and edit an MPH-file at the same time. If you try to open an MPH-file that is already open in another user's COMSOL Desktop, that MPH-file is locked, and you get an option to open the MPH-file in a read-only mode (click **Open As Read-Only**). That means that you can edit the model but you cannot save it unless you save the MPH-file under another name. When an MPH-file is locked, COMSOL creates a separate lock file with the same filename as the MPH-file plus the extension `.lock`, stored in the same directory as the locked MPH-file. If a lock file remains after all COMSOL Desktop sessions have ended (which can happen if the COMSOL Desktop session is ended in a nonstandard way), you can reset the lock when trying to open the file the next time by clicking **Reset Lock and Open**.

Linux and macOS do not support operating system locking of files. On those platforms, locking is supported to help users avoid editing the same COMSOL Multiphysics model file, but it is possible to ignore the file locking and delete the lock files.

MODEL FILES FOR JAVA

Editable script files that contain sequences of COMSOL commands as Java code (see the *COMSOL Multiphysics Programming Reference Manual* for more information about these commands). You can compile these Java files and run them as separate applications. Edit the files in a text editor to add additional commands. For parts of the model that appears under a component (such as the geometry, physics, and mesh), the default format is to include the component level in the Java code. If you want do not want to include the component level, clear the **Use component syntax** check box on the **Methods** page in the **Preferences** dialog box.

When saving a Model Java-file history for running a method call in the COMSOL Desktop, it contains the history produced while running the method call and not the method itself.

MODEL FILES FOR MATLAB

Model files for MATLAB are editable script files (M-files), similar to the model files for Java, for use with MATLAB. A model file for MATLAB contains a sequence of COMSOL commands as an M-file. You can run these model files in MATLAB like any other M-file scripts. You can also edit the files in a text editor to include additional COMSOL commands or general MATLAB commands.

Running model files in the M-file format requires LiveLink™ for MATLAB®.

MODEL FILES FOR VBA

Model files for VBA are editable script files (VBA-files), similar to the model files for Java, for use with VBA (Visual Basic for Applications) in Microsoft Excel®. A model file for VBA contains a sequence of COMSOL commands as a VBA-file (extension .vba). You can use these files from Excel® to access settings and data in COMSOL models.

Using model files in the VBA format requires LiveLink™ for Excel®.

- [The Application Libraries Window](#)
- [Saving COMSOL Files](#)
- [Reverting to the Last Saved File](#)
- [Printing and Capturing Screenshots](#)
- [Saving and Opening Recovery Files](#)

Saving COMSOL Files

The following options are selected from different menus and toolbars as described in [The COMSOL Desktop Menus and Toolbars](#).

SAVING A NEW MODEL OR APPLICATION

If this is the first time saving a model or application, or if you want to update the file and keep the current name and format, in general, these are the ways to save a model:

- Click the **Save** button () on the Quick Access Toolbar or Main Toolbar.
- Press Ctrl+S.
- Select **File>Save**.

If you save a model that was previously saved in an earlier version of COMSOL Multiphysics, you get a question about if you want to continue to save the model file, thereby overwriting the original file with a new file that has been converted so that it can only be opened in version 5.4. Select the **Do not show this message again** check box if desired. There is also a preference setting on the **Files** page in the **Preferences** dialog box. Under **Saving COMSOL application files**, clear the **Warn before overwriting a file saved by an older version of COMSOL** check box (selected by default) to turn off this question.

CREATING A COPY USING SAVE AS

If the model has been saved before and you want to create a copy you can choose to save in one of the COMSOL file formats (see [COMSOL MPH-Files](#), [Model Files for Java](#), and [Model Files for MATLAB](#)).

Select **File>Save As**. The **Save As** window opens, and from the **Save as type** list select **COMSOL Application (*.mph)** (the default), **Model file for Java (*.java)**, **Model file for MATLAB (*.m)**, or **COMSOL File for VBA (*.vba)**.

In all cases, navigate to the location where you want to save the model, enter a **File name**, and then click **Save**.

You can add the author to the header of model files for Java and for MATLAB that are saved. Open [The Preferences Dialog Box](#) and under **General>History export**, select the **Include author** check box.

REVERTING TO THE LAST SAVED FILE

To open the last saved version of the file and reinitialize the GUI, select **File>Revert to Saved** (). For Windows users, you can also customize the Quick Access Toolbar and then click the **Revert to Saved** button.

COMPACTING THE HISTORY

The COMSOL files for Java and for MATLAB contain the entire history of the model, including settings that are no longer part of it. To compact the history so that the files only include the settings that are part of the current model, select **File>Compact History**. For Windows users, you can also customize the Quick Access Toolbar and then click the **Compact History** () button.

Compacting the history works best if you make sure that the geometry is built before running **File>Compact History**.

WHEN SAVING, OPTIMIZING FOR SPEED OR FILE SIZE

You can choose to save COMSOL files (MPH-files) that are optimized for speed (the default, using uncompressed files that are faster to save) or optimized for file size (using compressed files). In the **Preferences** dialog box (see [Preferences Settings](#)), click **Files** and choose **Speed** or **File size** from the **Optimize for** list under **Saving COMSOL application files**.

- [About the COMSOL Model File Formats](#)
- [Windows Toolbars and Menus](#)
- [The Root Settings and Properties Windows](#)
- [Printing and Capturing Screenshots](#)

Saving and Opening Recovery Files

The COMSOL Multiphysics software can store recovery files each time you start a solver. This setting is initially active by default. If the server has lost contact with the client, a recovery file is also saved or kept.

If any recovery files exist, the **Recovery Files** window is open when you start the COMSOL Desktop. You can also open the **Recovery Files** window from the **Windows** menu.

The update of the recovery file occurs at the following events:

- After completing the solution for each time step specified as the output times in the **Times** field for a time-dependent simulation.

- After completing each parameter step in a parametric simulation.
- After completing each successful Newton iteration for a nonlinear stationary simulation.

The recovery files are COMSOL MPH-files that represent the state at the time that they were saved. They make it possible to recover from a solver error, which can be especially useful for long time-dependent or parametric runs.

You can control the use of recovery files using the buttons at the top of the Recovery Files window:

- Click the **Open** button () to open a selected recovery file. Opening the recovery files this way ensures that the recovery file can be deleted without compromising the open model. It does not remove the recovery file when the open model is saved though
- Click the **Save and Open** () button saves the recovery file to a Model MPH-file and open it. It also removes the recovery file.
- Click the **Save As** button () to save the recovery file to a Model MPH-file and remove the recovery file.
- Click the **Delete** button () or press Delete to remove the selected recovery files.

The COMSOL Multiphysics software keeps track of the computed time steps or parameter steps in the recovery file, so right-click the **Study** node and select **Continue** () to continue the computation from the point where it was stored in the recovery file. If you are solving a stationary nonparametric problem, the last converged Newton iteration is stored in the recovery file; selecting **Continue** causes the software to resume solving from this stored state.

You can make changes to these default settings in [The Preferences Dialog Box](#) in the **Files** section.

- The **Save recovery file** check box is selected by default to save recovery files to disk during the solution process for time-dependent, parametric, and nonlinear solvers.
- In the **Folder for recovery files** field, you can specify a different folder from the default to, for example, use a folder on the server where there is more disk space for storing large recovery files. Click **Browse** to browse to a recovery file folder.
- In the **Folder for temporary files** field you can specify a different folder than the default to, for example, use a folder where there is more disk space for storing large temporary files. Click **Browse** to browse to a folder for temporary files.
- If you run the COMSOL Multiphysics software in a client-server configuration, you can specify a **Folder for temporary files on client** and a **Folder for temporary files on server**.

Studies and Solvers

The Root Settings and Properties Windows

The Root node is the topmost level of the Model Builder tree and the Explorer tree in the Application Builder. When you click this node, the **Settings** window for the **Root** node (, or in the Application Builder) opens and includes detailed information about the model file. To open the corresponding **Properties** window, right-click the **Root** node and choose **Properties** from the context menu.

ROOT SETTINGS WINDOW

Some of the fields can be edited directly in this window, while others display system information that cannot be changed, or information that changes as updates are made throughout the model (for example, adding a node that requires an additional module license).

- **Protection:** Click **Set Password** next to **Editing not protected** or **Running not protected** to enter a password in the **Protect Edit with Password** or **Protect Running with Password** dialog boxes. To change the password, click **Change**

Password to enter the previous password and a new password in the **Protect Edit with Password** or **Protect Running with Password** dialog boxes. Note that, for the password that protects editing, lost passwords cannot be recovered.

- **Used Products:** The information included here is based on the purchased license or modules. See [Checking and Controlling Products and Licenses Used](#). Also see [The About COMSOL Multiphysics Box](#).
- **Presentation:** In this section you can specify a title and a description of the model. By default, these texts are used on the title page of a report; see [The Title Page](#). Under **Computation time**, you can enter an expected computation time in the **Expected** field. Also, the time after **Last** is the last measured computation time (if available). To illustrate the model you can also set an image as a thumbnail that displays in this section, when opening a file in the **Application Libraries** window, and as the default report title page image. See the section [Setting and Clearing the Thumbnail Image](#) for details about how to do this.
- **Unit System:** The default unit system is SI units. Or select any other option from the list. See [Unit Systems](#) and [Setting the Unit System for Models](#) to change the setting globally or locally.
- **Graphics:** For specifying the color theme used for selection colors, use the **Color theme** list, where you can select from all available color themes. The default is to use the default color theme — for example, **Default from preferences (Default)**. You specify the default color theme in the **Preferences** dialog box, in the **Color theme** list on the **Graphics and Plot Windows** page. See [Selection Colors](#) for more information about selection colors.

For the **Font** settings, the default is to use the font family that is set in the **Preferences** dialog box — on the **Graphics and Plot Windows** page under **Default font** — with a default font size. Depending on the operating system and the installed fonts on the computer, you can select from a number of other font families from the **Family** list. The default font is indicated in the default settings for **Family (Default from preferences (Vera))**, for example. For the font size, the **Default size** setting in the **Size** list uses the font size that is used in the graphics and plots, which is a system-dependent value. You can also choose another font size between 6 and 24 points or type a font size in the **Size** combined field and list. The font and the font size affect text in the Graphics window and other plot windows in the COMSOL Desktop and in Graphics form objects in the Application Builder. See [Changing the Font for Plot Labels and Titles](#) to make global changes.

- **Applications** (this section is only available from the Application Builder window): Select the **Ask to save application when closing** check box to ask users if they want to save changes in an application when closing it. Also, from the **When starting with COMSOL Multiphysics** list, you can control the behavior when a user starts COMSOL Multiphysics with the option to open an application or when a user double-clicks an MPH-file in Windows: Select **Edit application** (the default) to open the COMSOL Desktop for editing the application, or select **Run application** to launch and run the application directly.

Select the **Ignore license errors during launch** check box to make it possible to start the application even if not all required licenses are available. It is, however, still not possible to use products when the license is not available, so available API methods will typically have to be used in the application to limit the application's functionality depending on what licenses are available.

ROOT PROPERTIES WINDOW

To access the **Properties** window, right-click the **Root** node and choose **Properties** from the context menu.

	You can change a filename by saving the file, but the root node <i>Name (root)</i> cannot be changed for this top level node. This is different than for other nodes in the tree, where the name can be edited. See Displaying Node Names, Tags, and Types in the Model Builder for information. Also see Settings and Properties Windows for Feature Nodes .
---	---

- **File:** The file location where a file is saved. This field cannot be edited, but is automatically updated when the file is saved to a new path. Also see [Documentation and Application Libraries Root Directories](#).

- **Version:** Includes the version and build of the COMSOL Multiphysics instance that you are running. This information is system generated.
- **Created** and **Last modified:** These sections cannot be edited and are automatically generated based on the computer system or network time and date settings.
- **Saved with license:** The license number of the installed software that the model or application was saved with is included here. Also see [The About COMSOL Multiphysics Box](#).
- **Application version:** Enter a tracking version number for the model or application (for example, **Internal Draft V1**, **Sales Demonstration V2**, or **Version B**).

Unit Systems

The COMSOL Multiphysics software supports the following unit systems:

METRIC UNIT SYSTEMS

- SI units, the International System of Units (SI, Système International d’Unités). This is the default unit system (sometimes also called MKS). For a list of SI units in COMSOL Multiphysics, see [SI Base, Derived, and Other Units](#).
- CGSA units. The CGS system uses centimeter, gram, and second as basic units of length, mass, and time, respectively. The remaining basic units are identical to the SI units. The CGS unit system gives nice values for small lengths, masses, forces, pressures, and energies when working on a microscale and with weak electromagnetic forces. The derived units of force, pressure, and energy have well-known and widely used names: dyne, barye, and erg, respectively. CGSA adds *ampere* as the basic unit for electric current. For a list of CGSA units, see [Special CGSA Units](#).
- Electromagnetic units (EMU). This system is based on Ampère’s law, which defines the unit of electric current once you select an appropriate value for the constant *C*. When dealing exclusively with magnetic effects, it is convenient to set *C* = 1. If CGS units are used for the remaining basic dimensions, the current unit is called an *abampere*, and the corresponding coherent unit system is called electromagnetic units. Unique names for derived units have been introduced by prefixing the SI name with *ab-*. For a list of EMU units, see [Special EMU Units](#).
- Electrostatic units (ESU). Based on Coulomb’s law for the force between point charges, ESU uses a unit of charge called the *statcoulomb* with CGS units for length, mass, and time. From there, the *statampere*, or *franklin*, and other derived units of the electrostatic unit system follow. For a list of ESU units, see [Special ESU Units](#).
- MPa units. For stationary structural mechanics, where the density does not appear in the equations, it can be convenient to use a system where newton and megapascal (hence the name “MPa system”) are naturally derived units of force and pressure, respectively. Keeping the SI unit for time, the basic units of length and mass become millimeter and tonne. Except for the force and pressure units, other derived units are nameless. For a list of MPa units, see [Special MPa Units](#).

ENGLISH UNIT SYSTEMS

- Foot-pound-second unit system (FPS units). The original foot-pound-second system seems to be the absolute system using the pound as a unit of mass. This version of the FPS system is in agreement with the IEEE standard (the pound is a unit of mass and not of force). The natural derived unit of force is the *poundal*. For a list of FPS units, see [Special FPS Units](#).
- British engineering units. An alternative to the standard FPS system is the British engineering unit system (also called gravitational foot-pound-second system or foot-slug-second system). Here, the pound force is the natural unit of force, which causes the introduction of the mass unit *slug* such that a pound force is a slug-foot per second squared. For a list of British engineering units, see [Special British Engineering Units](#).

- Inch-pound-second unit system (IPS units). It is possible to define varieties of the FPS and British engineering systems based on the inch instead of the foot as basic unit of length. This gives rise to two distinct inch-pound-second systems: the *absolute IPS system* (just called IPS) and the *gravitational IPS system*. For a list of IPS units, see [Special IPS Units](#).
- Gravitational IPS units. This alternative IPS unit system considers the pound a unit of weight rather than a unit of mass. For a list of Gravitational IPS units, see [Special Gravitational IPS Units](#).

OTHER

- None. No units appear in the settings, which can be useful in nondimensionalized (de-dimensionalized or dimensionless) models.

- [Using Units](#)
- [Setting the Unit System for Models](#)

Searching and Finding Text

Press Ctrl+F to open a **Find** tool that you can use to search for variables or text in all of the model or, for application development, only in methods. In the **Find** tool, click **All** to search the entire model, including user interface components, variable definitions, model entity tags, identifiers, and labels. You can specify to search using an **Exact match**, a **Regular expression**, or a **Case sensitive** search by selecting the corresponding check boxes. Windows users can also customize the Quick Access Toolbar to access this button (🔍).

Click **Methods** to find and optionally replace a text string in methods developed for an application. See the Application Builder documentation for details.

Click **Advanced** to access some advanced search tools. See [Advanced Search Options](#) below.

Click the **Find** button to launch the search. The search results for each search appears in a separate **Find Results** window, where each occurrence of the search string appears in a row. Double-click the row to open the node or method and highlight the search result in the Settings window or method where it occurs. The **Node** column lists the node where the search string appears; the **Type** column lists the type of the search results, such as **Setting**, **Description**, or **Method**; and the **Text** column shows the text in which the search string appears.

ADVANCED SEARCH OPTIONS

Click **Advanced** to enable a more specific search method where individual types of candidates can be searched for. In the **Find** field, type a search query in the same way as on the **All** page using an **Exact match**, a **Regular expression**, or a **Case sensitive** search, if desired. In the **Filter** section, below the **Find** field, use the **Include** list to specify what to include: **Node tags**, **Node labels**, **Node names**, **Node types**, **Descriptions**, and **Settings**. The **Include** list specifies what you search for, so selecting **Node tags**, for example, only matches the query in the **Find** field against node tags. The option **Descriptions** searches for any fixed text in the COMSOL Desktop but not text that can be changed such as lists. The **Settings** option searches for values of a setting (for example, text in a text field or in a list). In addition, it is possible to add a name query in the **Name filter** field. Any nonempty entry here will only include settings with a specific name, which is the description of the setting. This query is also affected by the settings for the **Exact match**, **Regular expression**, and **Case sensitive** check boxes. Select the **Include API names in search** check box to allow the search filter to match against the API names. It is only applicable when searching for **Node types** and **Settings** and checks the API names of the following search candidates:

- The query in the **Name filter** field is matched against the API name of a setting (for example, the **Axis type** list in a **Block** geometry feature has **axistype** as its API name).
- The query in the **Find** field is matched against the API value of list settings (for example, the option **x-axis** in the **Axis type** list has the API value **x**).

- A search for the value of a check box (typically **on** or **off**) is ignored in normal searches but is active when including API names. The **Find** field can then match values that are on or off for most check boxes.
- For the **Node types** option in the **Include** list, which otherwise searches for the descriptive string of the type but now also includes the API name of the type (for example, the **Work Plane** geometry feature has the API type **WorkPlane**).

ADDITIONAL SEARCH TOOLS FOR THE PHYSICS BUILDER

When searching in the Physics Builder, you can also control the scope of the search in the **Find** tool. In addition to physics builder files, it can also search in linked files. A linked file can either be a file in an **Import** node under the **External Resources** branch (downward search), or a file listed in the **External Resources** links in the table of the root node's Setting window (upward search). The search can look for files in the upward direction by selecting the **Follow link sources** check box, and it can look for files in the downward direction by selecting the **Follow imports** check box. A **Depth** value can be used to limit the search. Under the **Links** tab there is a specialized search that finds links to a selected node. It supports the **Follow link sources** option, and only need to search upward one level. It is not applicable for nodes that cannot be a target of a link.

The Application Libraries Window

The **Application Libraries** window (Figure 2-12) contains sets of models and applications that you can use for a variety of purposes: for learning how to build COMSOL models, as starting points for your own models and applications, and as demonstrations of specific functionality. Each add-on module includes its own application library with information about how to use the module within its application areas. Each file includes full documentation and a brief description, including the solution times and information about the computer used for solving the model.

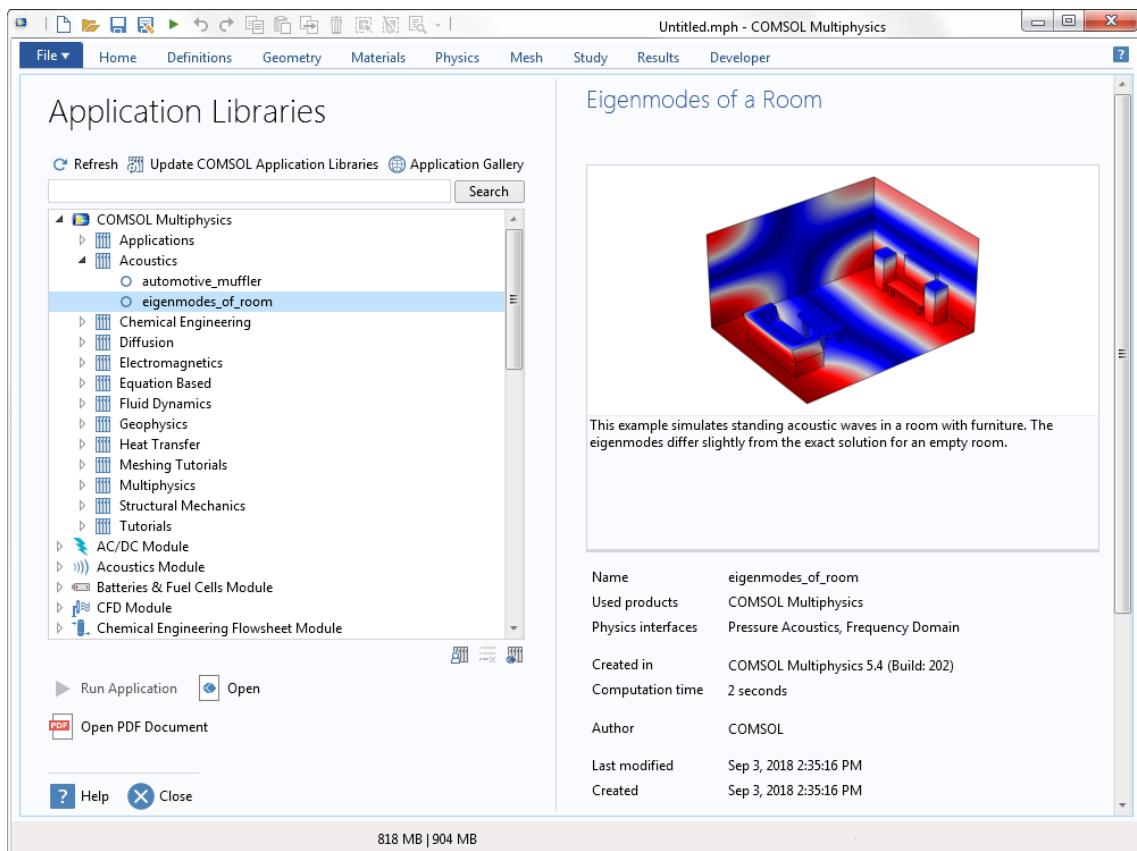

Figure 2-12: The Application Libraries window with Eigenmodes of a Room highlighted in the tree. Specific information about the model or application is displayed to the right, including its name and the computation time.

Browse through the **Application Libraries** tree to see what is available for your license. Click to highlight the file in the tree and read the information about it to the right, or search for a specific application. The information for each application includes:

- The COMSOL products used.
- The physics interfaces used.
- The version that the application was created in.
- The computation time. If you hover over the computation time, a tooltip displays information about the computer used for the computation (CPU, clock rate, and number of cores) and, if applicable, the solution times for each study step.
- The dates and times for when the application was created and last modified.

Win Mac Linux	<p>To open the Application Libraries window ():</p> <ul style="list-style-type: none"> From the Home toolbar, Windows menu, select Application Libraries. You can also customize the Quick Access Toolbar and then click the Application Libraries button on the toolbar. See Windows Toolbars and Menus. From the File menu select Application Libraries.
	<p>To open the Application Libraries window ():</p> <ul style="list-style-type: none"> In the Main toolbar, click the Application Libraries button. Select Windows>Application Libraries.

The following sections describe what is available and what you can do from the **Application Libraries** window:

- [The Applications Folders](#)
- [Running or Opening a Model or Application and Its Documentation](#)
- [Downloading MPH-Files With Solutions](#)
- [Searching the Application Libraries](#)
- [The Application Library Update Window](#)

You can also set the root directory and create and remove a user-defined library as described next.

APPLICATION LIBRARY PREFERENCES

The following settings can be modified using the buttons at the bottom of the **Application Libraries** tree on the **Application Libraries** page in [The Preferences Dialog Box](#) and — if the **Allow managing libraries in the Application Libraries window** check box on that page is selected (the default) — also in the **Application Libraries** window itself.

Add User Application Library

Click the **Add User Application Library** button () to add customized folders. In the **Add User Application Library** dialog box, navigate to a location on your computer and select an existing directory or click **Make New Folder** to create a custom folder. Click **OK** to save the changes and exit, or **Cancel** to exit without saving.

It is not possible to add an application library identical to, containing, or being contained in, an already used application library.

Optionally, you can replace the standard folder icon () with custom icons of your choice that reflect the content of your library folders. To use a custom icon for a folder, create a PNG-file with an image size of 16-by-16 pixels and save it in the folder under the name `folder.png`.

Set the COMSOL Application Libraries Root

Click the **Set COMSOL Application Libraries Root Directory** button () to edit or set the root folder. This redirects the COMSOL software to a different folder where customized applications can be stored.

In the **Set COMSOL Application Libraries Root Directory** dialog box, navigate to the new root folder location or click **Make New Folder**. Click **OK** to save the changes and exit, or **Cancel** to exit without saving.

Remove Selected Library

This button is enabled after a user application library folder has been created. Select a user application library root folder in the **Application libraries** tree and then click the **Remove Selected** () button to remove the library from the tree.

The Applications Folders

In the **Applications** library folders you find runnable applications with custom user interfaces tailored with the Application Builder to simplify solving a specific problem using COMSOL Multiphysics. To run an application, click the () **Run Application** button. If, instead, you want to explore how the application is constructed, click () **Open**. For applications in this folder, clicking the () **Open PDF document** button launches the PDF document that you can access from the running application. If no such document is available, this button is not activated. For further details, see the next section.

Running or Opening a Model or Application and Its Documentation

There are two file formats to choose from in the tree, full and compact, and these are further defined by the type of application. Some applications might have been delivered with an MPH-file that contains no stored meshes or solutions. Such compact files are indicated by the icon  . Full models are indicated by the icon  . See [Downloading MPH-Files With Solutions](#).

RUNNING AN APPLICATION

You can run an application built with the Application Builder by clicking  **Run application**. This button is not activated for models.

OPENING A MODEL OR APPLICATION

Once you have located the file you want to open — for example, you used a search and it is successful (see [Searching the Application Libraries](#)), or you browsed the Application Libraries tree — then to open the file:

- Double-click the name in the tree.
- Select the name, then click  **Open**.
- Right-click the name, then from the context menu select  **Open**.

It is possible to open and postprocess models that include functionality that you have blocked or that your license does not include. Nodes with functionality that requires a license for a product that is blocked or not available get a **License Error** subnode (), where you find information about the missing but required product license. Unless you disable or remove such nodes, it is not possible to re-solve such models.

OPENING A PDF DOCUMENT

To read the documentation in PDF format, including step-by-step instructions:

- Click to highlight the name in the tree, then click  **Open PDF Document**.
- Right-click the name, then from the context menu select  **Open PDF Document**.

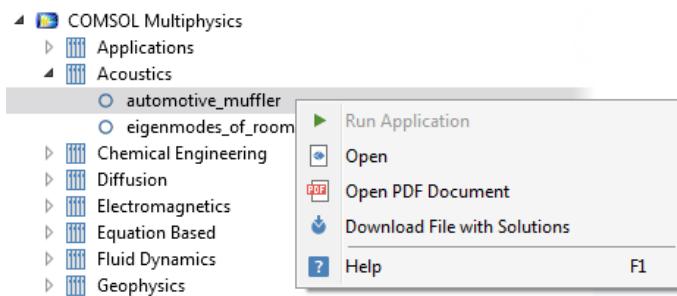

You can enable the **Open PDF Document** button for a user-library model or application by placing a PDF-file with the same name as the MPH-file in the same folder.

OPENING THE APPLICATION GALLERY

The Application Gallery, which is a part of the COMSOL website, provide access to a large number of models and applications, and you can download the MPH-files, PDF documentation, and other related files to extend the application libraries. Click the **Application Gallery** button (🌐) above the application libraries tree to open the Application Gallery in a web browser.

Downloading MPH-Files With Solutions

You can download the MPH-files complete with solutions via **Application Library Update** (see [The Application Library Update Window](#)). Alternatively, right-click a compact node (🌐) in the **Application Libraries** tree and choose  **Download File with Solutions**.

You can also generate the complete models by building the mesh sequences and computing the studies.

The procedure for restoring the solutions can involve other steps, such as adjusting physics interface settings. See the individual documentation for details if the simple approach does not work.

Searching the Application Libraries

In the **Application Libraries** window, you can **Search** the application libraries to find any files using a specific feature. For example, enter all or part of the name, a physics interface name, a feature name, a feature tag or name prefixed by '@', or any other phrase or words or and click **Search**.

By default, the search includes all words in the **Search** field..

COMSOL files are named using an underscore between words (for example, *effective_diffusivity*) because the filename is also the name of the corresponding Model MPH-file. The underscore is required to form a valid filename, so it is recommended that you, if you are not sure of the full name, enter only the first word (rather than multiple words separated by spaces) in the **Search** field when searching for a model or application name.

The search in the **Application Libraries** window does not include the models' PDF documents. To search for text in the model documentation, use the COMSOL Documentation window and select **Application libraries** from the **Search scope** list to limit the search for the application libraries (see [Searching the Documentation](#)).

SEARCH PARAMETERS

- To search for models and applications by filename only, use the prefix “@name:”, for example @name:busbar. You can also use the wildcard character ‘*’ at the beginning and the end of the search expression, for example @name:fluid* or @name:*electr*.
- If you enter more than one search term separated by spaces (in a search that is not restricted to filename using the “@name” prefix), the search finds models where all of the search terms appear.
- Limit the search to tags, names, or types with the prefix ‘@’. For example, @genext finds all models using a General Extrusion node, and @ehs finds all models with an Electron Heat Source node.
- To search for a specific physics interface, use the scoping syntax @physics:<name>. For example, enter @physics:ec to find all models that use the Electric Currents interface.
- In addition to @physics, the supported scopes include @geom, @mesh, @probe, @result, @selection, and @study. For example, enter @geom:if to search for models that include an If statement (node) in the geometry sequence.

If the search does not return any results, the Application Libraries window contains the message **No Results Found**. Click the **Refresh** button () under the tree to return to the root **Application Libraries** folder list.

The Application Library Update Window

Application Library Update is a service that provides new and updated models and applications for the application libraries of the COMSOL products that your license includes. The text below describes how to use the Application Library Update service.

Using the COMSOL **Application Library Update** service requires internet access. For a default installation, you also need to run COMSOL as an administrator. See [Proxy Server Settings](#) section below for instructions on how you can modify your installation to avoid this restriction.

APPLICATION LIBRARY UPDATE

Open the **Application Library Update** window by clicking **Update COMSOL Application Libraries** in the **Application Libraries** window or by going to the **File>Help** menu (Windows users) or the **Help** menu (macOS and Linux users) and choosing **Update COMSOL Application Libraries** ().

When the **Application Library Update** window opens, click to select if you download a file contact solutions or more compact versions of the models and applications, then click **Find Applications** to check to see if all these models and applications are up to date. If the message **Your Application Libraries are up to date** displays, no updated or new models or applications are available.

If the library is not up to date, browse the list that appears with a description and image. Choose which ones to download by selecting or clearing the check boxes next to the thumbnail images. By default all check boxes are selected; by clicking **Uncheck all** and **Check all** you can change the global selection state.

Click the **Download Selected** button to download the selected models and applications, or click the **Download All** button. The download time depends on the size of the files, which is listed for each file, and the bandwidth of the internet connection.

Also see the *Introduction to Application Builder*.

Proxy Server Settings

If you connect to the internet through a web proxy, you can specify the required settings in the **Help** section of the Preferences dialog box; for details, see [Proxy Server Settings](#).

DESTINATION DIRECTORIES FOR LIBRARY UPDATES

To edit these settings under **Destination directories for library updates**, open [The Preferences Dialog Box](#) and go to the **Updates** section.

The **Destinations** list provides two options for specifying which application, documentation, and part directories are synchronized with the COMSOL Multiphysics server when you launch an Application Library Update or Part Library Update (see the next section) request:

- **Current directories** (default): Synchronize with application MPH-files under the COMSOL Application Libraries root set on the **Preferences** dialog's **Application Libraries** page, with documentation files under the directory specified in the **Documentation root directory** field on the **Preferences** dialog's **General** page, and with part MPH-files under the COMSOL Part Libraries root set on the **Preferences** dialog's **Part Libraries** page.
- **Specify custom directories**: Choosing this option lets you specify COMSOL Application Libraries, documentation, and COMSOL Part Libraries root directories separate from those of your current COMSOL Desktop environment.

By default, the COMSOL Application Libraries, COMSOL Part Libraries, and documentation root directories are located directly under the COMSOL installation root directory, in **applications/**, **parts/**, and **doc/**, respectively. This typically implies that special permissions are required for saving downloaded files, and it can therefore be beneficial to move or copy the directories to a different location. The settings referred to in this section are provided to let you customize Application Library Update to the IT environment of your organization.

The Part Library Update Window

Part Library Update is a service that provides new and updated geometry parts for the part libraries of the COMSOL products that your license includes. The text below describes how to use the Part Library Update service.

Using the COMSOL **Part Library Update** service requires internet access. For a default installation, you also need to run COMSOL as an administrator. If you connect to the internet through a proxy server, see the [Proxy Server Settings](#) section for the relevant settings.

PART LIBRARY UPDATE

Open the **Part Library Update** window by clicking **Update COMSOL Part Libraries** in the **Part Libraries** window or by going to the **File>Help** menu (Windows users) or the **Help** menu (macOS and Linux users) and choosing **Update COMSOL Part Libraries** ().

If the message **Your Part Libraries are up to date** displays when the **Part Library Update** window opens, no updated or new geometry parts are available. If the library is not up to date, browse the list that appears with a description and image. Choose which ones to download by selecting or clearing the check boxes next to the thumbnail images. By default all check boxes are selected; by clicking **Uncheck all** and **Check all** you can change the global selection state.

Click the **Download Selected** button to download the selected geometry parts, or click the **Download All** button. The download time depends on the size of the files, which is listed for each geometry part, and the bandwidth of the internet connection.

The Physics Interfaces

This section is an overview of the core physics interfaces included with a COMSOL Multiphysics license. If your license include add-on modules, there are additional physics interfaces described in the individual documentation for each module.

- [Building Models in the Model Builder](#)
- [Adding and Inserting Physics Interfaces](#)
- [Modeling Guidelines](#)
- [Creating a New Model](#)

Introduction to the Physics Interfaces

Solving PDEs generally means you must take the time to set up the underlying equations, material properties, and boundary conditions for a given problem. COMSOL Multiphysics, however, relieves you of much of this work. The software provides a number of *physics interfaces* that consist of nodes and settings that set up the equations and variables for specific areas of physics. An extensive set of physics-dependent variables makes it easy to visualize and evaluate the important physical quantities using conventional terminology and notation.

Suites of physics interfaces that are optimized for specific disciplines together with specialized application libraries are available in a group of optional products. See [The COMSOL Multiphysics Modules and Interfacing Options](#).

A complement to the interfaces for physics, special interfaces for equation-based modeling simplify the setup of PDEs for modeling that does not explicitly refer to any particular application field. In addition, other interfaces supplement the physics with special functionality such as the Sensitivity and Moving Mesh user interfaces.

- [Physics Groups and Subgroups](#)
- [Physics Interface Guide](#)
- [Selecting Physics Interfaces](#)

Physics Groups and Subgroups

The [Select Physics](#) page in the **Model Wizard**, as well as [The Add Physics Window](#), contain groups and subgroups of physics and mathematics interfaces (some items only display if a license includes the corresponding add-on modules).

RECENTLY USED (🕒)

This group contains the most recently used physics interfaces for easy access.

AC/DC (⚡)

This group contains physics interfaces for low-frequency electromagnetics such as electrostatics and electric currents. It has the Particle Tracing subgroup, which requires the Particle Tracing Module.

ACOUSTICS ()

This group contains acoustics-based physics interfaces. Except for the Pressure Acoustics group, these subgroups require additional licenses:

- Acoustic-Structure Interaction
- Aeroacoustics
- Thermoviscous Acoustics
- Ultrasound
- Geometrical Acoustics

CHEMICAL SPECIES TRANSPORT ()

This group contains chemical species transport physics interfaces used, for example, for convection and diffusion, solving for the species concentrations and for chemical reactions. These subgroups are available depending on the specific license:

- Moisture Transport
- Reacting Flow (including an additional Turbulent Flow subgroup)
- Reacting Flow in Porous Media
- Rotating Machinery, Rotating Flow

ELECTROCHEMISTRY ()

This group contains electrochemistry physics interfaces for modeling electrochemical components such as batteries and fuel cells. This group and its subgroups are only available with additional licenses:

- Battery Interfaces
- Corrosion, Deformed Geometry
- Electrodeposition, Deformed Geometry

FLUID FLOW ()

This group contains fluid flow physics interfaces such as laminar single-phase flow and, with add-on modules, multiphase flow and turbulent flow. These subgroups are available based on the license:

- Single-Phase Flow (including additional Turbulent Flow and Rotating Machinery, Fluid Flow subgroups)
- Thin-Film Flow
- Multiphase Flow (including additional Bubbly Flow; Mixture Model; Euler-Euler Model; Two-Phase Flow, Level Set; Two-Phase Flow, Phase Field; Two-Phase Flow, Moving Mesh; Three-Phase Flow, Phase Field; and Rotating Machinery, Multiphase Flow subgroups)
- Porous Media and Subsurface Flow
- Nonisothermal Flow (including additional Turbulent Flow and Rotating Machinery, Nonisothermal Flow subgroups).
- High Mach Number Flow (including an additional Turbulent Flow subgroup)
- Rarefied Flow
- Particle Tracing

HEAT TRANSFER ()

This group contains physics interfaces for heat transfer in solids, fluids, pipes, and in porous media. Other physics interfaces are available for bioheat transfer and for heat and moisture transport. There are also multiphysics

interfaces for thermal multiphysics applications such as Joule heating. These subgroups are available depending on the specific license:

- Heat and Moisture Transport
- Thin Structures (for heat transfer in thin shells, thin films, and fractures)
- Conjugate Heat Transfer (including an additional Turbulent Flow subgroup)
- Radiation
- Electromagnetic Heating

OPTICS ()

This group contains physics interfaces for electromagnetic wave propagation in linear and nonlinear optical media for accurate component simulation and design optimization. This group and the subgroups are only available with additional licenses

- Ray Optics
- Wave Optics

PLASMA ()

This group contains physics interfaces for plasma modeling. This group and the Equilibrium Discharges subgroup require the Plasma Module.

RADIO FREQUENCY ()

This group contains physics interfaces for high-frequency electromagnetic field simulations solving the full Maxwell equations. This group is only available with the RF Module.

SEMICONDUCTOR ()

This group contains physics interfaces that solves Poisson's equation for the electric potential and the drift-diffusion equations for electrons and holes in a semiconductor material: Semiconductor interfaces and interfaces for solving the Schrödinger and Schrödinger-Poisson equations. This group is only available with the Semiconductor Module.

STRUCTURAL MECHANICS ()

This group contains structural mechanics physics interfaces for example to study displacements and stresses in solids and for multibody dynamics, fatigue, thermal stress, piezoelectricity, and other structural multiphysics couplings.

MATHEMATICS ()

This group contains mathematics interfaces for solving PDEs, ODEs, and DAEs, for optimization (which requires the Optimization Module) and sensitivity analysis, and for modeling moving meshes and parameterized geometry. These subgroups are available:

- PDE Interfaces (including a Lower Dimensions subgroup)
- ODE and DAE Interfaces
- Optimization and Sensitivity
- Classical PDEs
- Moving Interface (available with either the CFD Module or Microfluidics Module)
- Deformed Mesh
- Wall Distance

- Mathematical Particle Tracing (available with the Particle Tracing Module)
- Curvilinear Coordinates

For a list of all the physics interfaces under each group and subgroup, see the individual documentation included with each add-on module. Or search the online Help for the key words *Physics Interface Guide*.

- [Physics Interface Guide](#)
- [Selecting Physics Interfaces](#)

Adding and Inserting Physics Interfaces

THE ADD PHYSICS WINDOW

The **Add Physics** window is similar to the **Select Physics** window accessed through [The Model Wizard](#). It has the same physics interfaces available. This window is a quick way to add physics interfaces to models.

To open the **Add Physics** window:

- Right-click a **Component** node and choose **Add Physics**.
- From the **Home** toolbar, click **Add Physics**
- Select **Windows>Add Physics**.
- From the **Physics** toolbar, click **Add Physics** .

- Right-click a **Component** node and choose **Add Physics**.
- In the **Model Toolbar**, click **Add Physics** .
- In the **Physics Contextual Toolbar**, click **Add Physics** .
- Select **Windows>Add Physics**.

The **Add Physics** toolbar button is a toggle button: Click it again to close the **Add Physics** window.

TO ADD PHYSICS INTERFACES TO A MODEL COMPONENT

- I In the **Add Physics** window, either enter a **Search** term or navigate the tree to locate the physics interface to be added to the **Component**.

The tree organizes the available physics interfaces by application areas such as fluid flow, heat transfer, and structural mechanics. The physics interfaces found in the modules your license supports display in the different application areas. In some cases, licensing of a module adds physics interfaces to these application areas as well as attributes to existing physics interfaces, which are enhanced with additional functionality. The **Recently**

Used branch lists the last five physics interfaces used in recent modeling sessions. You can also enter a text string in the search field and click the **Search** button to list all the interfaces with the search term.

The contents of the **Add Physics** window depends on the space dimension of the active model component. If there are no **Component** nodes in the model, the list of physics interfaces is empty.

- 2 Once a physics interface is clicked, review and optionally modify any dependent variable names in the **Dependent Variables** section and, for some physics interfaces, specify the number of dependent variables. For PDE interfaces under **Mathematics**, you can also click the **Units** tab to specify units for the equation by defining a unit through a physical quantity for the dependent variable and the source term. See [Units](#) for more information about these settings.
If you select multiple physics interfaces, the **Dependent Variables** section is not available.
- 3 When there is already a physics interface added to the Component, the existing **Studies** are listed under **Physics interfaces in study**. By default, the studies appear with a check mark () in the **Solve** column, which indicates that the study solves for the dependent variables in the physics interface. Click in the column to clear the check mark and exclude the physics interface from that study.
- 4 Click the **Add to Component** or **Add to Selection** buttons.
 - If **Add to Component** is selected, the physics interfaces are added to the **Model Builder** and become active in the entire model component's geometry by default. You can also press Enter to add the physics components to the component.
 - If **Add to Selection** is selected, the physics interfaces are added to the selected geometric entities in the **Graphics** window and new nodes are added to the **Model Builder**. This is a method called preselection.

COPYING, PASTING, AND INSERTING PHYSICS INTERFACES

You can copy and paste physics interfaces within a COMSOL Multiphysics session and also between COMSOL Multiphysics sessions, as long as the copied physics interface information remains in the clipboard.

To copy a physics interface with all its subnodes, right-click the physics interface node and choose **Copy** (or, for Windows users, click **Copy** on the Quick Access Toolbar). You can then paste it in the same or a new COMSOL Desktop session by right-clicking a compatible **Component** node and choosing, for example, **Paste Solid Mechanics** (or, for Windows users, click, for example, **Paste Solid Mechanics** on the Quick Access Toolbar).

It is also possible to insert physics interfaces from another COMSOL Multiphysics model into a model component. To do so, right-click a **Component** node and choose **Insert Physics from Model**. An **Insert Physics** dialog box appears where you can browse or type the path and name of the COMSOL Multiphysics model file from which you want to insert components in the **Model** field. Select one or more of the physics interfaces in the model from the **Physics** list and then click **OK** to insert them into the current model. The list includes the space dimension for the physics interface so that you can select compatible physics interfaces.

You can insert a physics from another space dimension if it is applicable in the component you insert it into. Most physics applicable in 2D axial symmetry is applicable in 3D, so an interface specified in a 2D axisymmetric component can therefore be inserted in a 3D component.

Some aspects when inserting or pasting a physics interface into an existing model component:

- All selections of a physics interface and its physics features depend on the geometry they belong to. When you insert or paste a physics interface into another component and geometry, there is a high risk of that selections change or become empty.
- Any references to named selections will be broken, and no selection nodes are included automatically in the insertion process.
- All use of global parameters, functions, variables, materials, multiphysics couplings, and coordinate systems will be invalid after the insertion process unless an item with the same name exists in the target component. No attempt is made to automatically include any item in the insertion process. Materials should be of minor importance if the physics interfaces consistently use the option **From material** in all their material property settings.
- Some physics features are not applicable in all dimensions, so these will simply be ignored. You will be notified about this in the message dialog box.

Altogether, these aspects may cause an insert or paste operation to be incomplete to some degree. In some cases, the difference is reported in a message dialog box after the insertion process has finished. Click **Cancel** in this dialog box to revert the insertion process.

Physics Interface Guide

The table lists the physics and mathematics interfaces in COMSOL Multiphysics and the availability for 1D, 1D axisymmetric, 2D, 2D axisymmetric, and 3D geometries.

PHYSICS INTERFACE	ICON	TAG	SPACE DIMENSION	AVAILABLE PRESET STUDY TYPE
AC/DC				
Electric Currents		ec	All dimensions	Stationary
Electrostatics		es	All dimensions	Stationary; Time Dependent
Magnetic Fields		mf	2D, 2D axisymmetric	Stationary; Frequency Domain
Acoustics				
Pressure Acoustics				
Pressure Acoustics, Frequency Domain		acpr	All dimensions	Eigenfrequency; Frequency Domain
Chemical Species Transport				
Transport of Diluted Species		tds	All dimensions	Stationary; Time Dependent

PHYSICS INTERFACE	ICON	TAG	SPACE DIMENSION	AVAILABLE PRESET STUDY TYPE
 Fluid Flow				
 Single-Phase Flow				
Laminar Flow		spf	3D, 2D, 2D axisymmetric	Stationary; Time Dependent
 Heat Transfer				
Heat Transfer in Solids		ht	All dimensions	Stationary; Time Dependent
Heat Transfer in Fluids		ht	All dimensions	Stationary; Time Dependent
 Electromagnetic Heating				
Joule Heating ¹ ,		—	All dimensions	Stationary; Time Dependent
 Structural Mechanics				
Solid Mechanics		solid	3D, 2D, 2D axisymmetric	Stationary; Eigenfrequency; Time Dependent
 Mathematics				
Wall Distance		wd	All dimensions	Stationary; Time Dependent
Curvilinear Coordinates		cc	All dimensions	Stationary; Eigenvalue
 PDE Interfaces				
Coefficient Form PDE		c	All dimensions	Stationary; Time Dependent; Eigenvalue
General Form PDE		g	All dimensions	Stationary; Time Dependent; Eigenvalue
Wave Form PDE		wahw	All dimensions	Time Dependent
Weak Form PDE		w	All dimensions	Stationary; Time Dependent; Eigenvalue
PDE, Boundary Elements		pdebe	3D and 2D	Stationary
 Lower Dimensions				
Coefficient Form Boundary PDE		cb	All dimensions	Stationary; Time Dependent; Eigenvalue
Coefficient Form Edge PDE		ce	3D	Stationary; Time Dependent; Eigenvalue

PHYSICS INTERFACE	ICON	TAG	SPACE DIMENSION	AVAILABLE PRESET STUDY TYPE
Coefficient Form Point PDE		cp	3D, 2D, 2D axisymmetric	Stationary; Time Dependent; Eigenvalue
General Form Boundary PDE		gb	All dimensions	Stationary; Time Dependent; Eigenvalue
General Form Edge PDE		ge	3D	Stationary; Time Dependent; Eigenvalue
General Form Point PDE		gp	3D, 2D, 2D axisymmetric	Stationary; Time Dependent; Eigenvalue
Weak Form Boundary PDE		wb	all dimensions	Stationary; Time Dependent; Eigenvalue
Weak Form Edge PDE		we	3D	Stationary; Time Dependent; Eigenvalue
Weak Form Point PDE		wp	3D, 2D, 2D axisymmetric	Stationary; Time Dependent; Eigenvalue
ODE and DAE Interfaces				
Global ODEs and DAEs		ge	All dimensions	Stationary; Eigenfrequency; Time Dependent; Frequency Domain; Eigenvalue
Domain ODEs and DAEs		dode	All dimensions	Stationary; Time Dependent; Eigenvalue
Events		ev	All dimensions	Time Dependent
Boundary ODEs and DAEs		bode	All dimensions	Stationary; Time dependent; Eigenvalue
Edge ODEs and DAEs		eode	3D	Stationary; Time dependent; Eigenvalue
Point ODEs and DAEs		pode	3D, 2D, 2D axisymmetric	Stationary; Time dependent; Eigenvalue
Optimization and Sensitivity				
Optimization Requires the Optimization Module		opt	All dimensions	Stationary; Eigenfrequency; Time Dependent; Frequency Domain; Eigenvalue
Sensitivity		sens	All dimensions	Stationary; Eigenfrequency; Frequency Domain; Eigenvalue; Time Dependent (available with the Optimization Module)
Classical PDEs				
Laplace Equation		lpeq	ID, 2D, 3D	Stationary
Poisson's Equation		poeq	ID, 2D, 3D	Stationary
Wave Equation		waeq	ID, 2D, 3D	Time Dependent

PHYSICS INTERFACE	ICON	TAG	SPACE DIMENSION	AVAILABLE PRESET STUDY TYPE
Helmholtz Equation		hzeq	ID, 2D, 3D	Stationary
Heat Equation		hteq	ID, 2D, 3D	Stationary; Time Dependent
Convection-Diffusion Equation		cdeq	ID, 2D, 3D	Stationary; Time Dependent
Stabilized Convection-Diffusion Equation		scdeq	ID, 2D, 3D	Stationary; Time Dependent
 Deformed Mesh				
Deformed Geometry		dg	All dimensions	Stationary; Time Dependent; Frequency Domain; Eigenvalue
Moving Mesh		ale	All dimensions	Stationary; Time Dependent; Frequency Domain; Eigenvalue

¹ This physics interface is a predefined multiphysics coupling that automatically adds all the physics interfaces and coupling features required.

Common Physics Interface and Feature Settings and Nodes

There are several common settings and sections available for the physics interfaces and feature nodes (Table 2-3). Some of these sections also have similar settings or are implemented in the same way no matter the physics interface or feature being used. There are also some physics feature nodes (Table 2-4) that display in COMSOL Multiphysics.

In each module’s documentation, only unique or extra information is included; standard information and procedures are centralized in this manual.

Table 2-3 has links to common sections and Table 2-4 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

SHOW MORE PHYSICS OPTIONS

To display additional sections and options for the physics interfaces (and other parts of the model tree), click the **Show** button () on the **Model Builder** and then select the applicable option.

After clicking the **Show** button, sections display on the **Settings** window when a node is clicked, or additional nodes are made available from the **Physics** toolbar or context menu.

- Selecting **Advanced Physics Options** either adds an **Advanced** settings section or enables nodes in the context menu or **Physics** toolbar. In many cases these options are described in the individual documentation.
- Selecting **Advanced Study Options** or **Advanced Results Options** enables options related to the **Study** or **Results** nodes, respectively.

For more information about the Show options, see [Advanced Physics, Study, and Results Sections](#) and [The Model Builder](#).

COMMON PHYSICS SETTINGS SECTIONS

TABLE 2-3: COMMON PHYSICS SETTINGS SECTIONS

SECTION	CROSS REFERENCE AND NOTES
Advanced Settings — Pseudo time stepping	Pseudo Time Stepping and Pseudo Time Stepping for Laminar Flow Models
Advanced Settings — Frames	See Frames .
Advanced	This section can display after selecting Advanced Physics Options. The Advanced section is often unique to a physics interface or feature node.
Anisotropic materials	For some User defined parameters, the option to choose Isotropic, Diagonal, Symmetric, or Anisotropic displays. See Modeling Anisotropic Materials for information.
Consistent Stabilization	See Stabilization .
Constraint Settings	Constraint Reaction Terms , Weak Constraints , and Symmetric and Nonsymmetric Constraints
Coordinate System Selection	Coordinate Systems Selection of the coordinate system is standard in most cases. Extra information is included in the documentation as applicable.
Dependent Variables	Predefined and Built-In Variables This section is unique for each physics interface, although some interfaces have the same dependent variables.
Discretization	Settings for the Discretization Sections
Discretization — Frames	See Frames .
Equation	Physics Nodes — Equation Section The equation that displays is unique for each interface and feature node, but how to access it is centrally documented.
Frames (Advanced Settings — Frames and Discretization — Frames)	Handling Frames in Heat Transfer and About Frames
Geometric entity selections	Working with Geometric Entities Selection of geometric entities (Domains, Boundaries, Edges, and Points) is standard in most cases. Extra information is included in the documentation as applicable.
Inconsistent Stabilization	See Stabilization .
Settings	Predefined and Built-In Variables Displaying Node Names, Tags, and Types in the Model Builder There is a unique Name for each physics interface.
Material Type	About Using Materials in COMSOL Multiphysics The Settings Window for Material Selection of material type is standard in most cases. Extra information is included in the documentation as applicable.

TABLE 2-3: COMMON PHYSICS SETTINGS SECTIONS

SECTION	CROSS REFERENCE AND NOTES
Model Inputs	<p>About Model Inputs and Model Inputs and Multiphysics Couplings</p> <p>Selection of Model Inputs is standard in most cases. Extra information is included in the documentation as applicable.</p> <p>To define the absolute pressure for heat transfer, see the settings for the Fluid node.</p> <p>To define the absolute pressure for a fluid flow interface, see the settings for the Fluid Properties node (described for the Laminar Flow interface).</p> <p>If you have a license for a nonisothermal flow interface, see that documentation for further information.</p>
Override and Contribution	<p>Physics Exclusive and Contributing Node Types</p> <p>Physics Node Status</p>
Pair Selection	<p>Identity and Contact Pairs</p> <p>Continuity on Interior Boundaries</p> <p>Selection of pairs is standard in most cases. Extra information is included in the documentation as applicable. Contact pair modeling requires the Structural Mechanics Module or MEMS Module. Details about this pair type can be found in the respective user's guide.</p>
Stabilization — Consistent and Inconsistent	<p>Numerical Stabilization, Numerical Stability — Stabilization Techniques for Fluid Flow and Heat Transfer Consistent and Inconsistent Stabilization Methods</p>

COMMON FEATURE NODES

TABLE 2-4: COMMON FEATURE NODES

FEATURE NODE	CROSS REFERENCE AND NOTES
Auxiliary Dependent Variable	Auxiliary Dependent Variable
Axial Symmetry	See Symmetry .
Continuity	<p>Continuity on Interior Boundaries and Identity and Contact Pairs.</p> <p>This is standard in many cases. When it is not, the node is documented for the physics interface.</p>
Discretization	Discretization (Node)
Equation View	<p>Equation View</p> <p>The Equation View node's contents is unique for each physics and mathematics interface and feature node, but it is centrally documented.</p>
Excluded Edges, Excluded Points, and Excluded Surfaces	Excluded Points, Excluded Edges, Excluded Surfaces
Global Constraint	Global Constraint . Also see the Constraint Settings section.
Global Equations	Global Equations
Harmonic Perturbation	Harmonic Perturbation , Prestressed Analysis , and Small-Signal Analysis
Initial Values	<p>Physics Interface Default Nodes, Specifying Initial Values, and Dependent Variables</p> <p>This is unique for each physics interface.</p>
Periodic Condition and Destination Selection	<p>Periodic Condition and Destination Selection</p> <p>Periodic Boundary Conditions</p> <p>Periodic Condition is standard in many cases. When it is not, the node is documented for the physics interface.</p>
Pointwise Constraint	Pointwise Constraint . Also see the Constraint Settings section.

TABLE 2-4: COMMON FEATURE NODES

FEATURE NODE	CROSS REFERENCE AND NOTES
Symmetry	Using Symmetries and Physics Interface Axial Symmetry Node . There is also information for the Solid Mechanics interface about Axial Symmetry. This is standard in many cases. When it is not, the node is documented for the physics interface.
Weak Constraint	Weak Constraint . Also see the Constraint Settings section.
Weak Contribution	Weak Contribution (ODEs and DAEs) and Weak Contribution (PDEs and Physics)
Weak Contribution on Mesh Boundaries	Weak Contribution on Mesh Boundaries
	<ul style="list-style-type: none"> • Creating a New Model • The Add Physics Window • Advanced Physics, Study, and Results Sections • Selecting Physics Interfaces

Creating a New Model

This section describes how to create a new model using [The Model Wizard](#) or to begin with a blank model. First you need to [Open a New Window to Begin Modeling](#). It is also useful to have a basic model added to the Model Builder; then you can experiment with [The Model Builder](#), which is described in the [Building a COMSOL Multiphysics Model](#) chapter.

Open a New Window to Begin Modeling

To open a **New** window:

- On the **Quick Access Toolbar** (Windows users) or the **Model Toolbar** (macOS and Linux users), click the **New** button ().
- Press Ctrl+N.
- Select **File>New**.

After the **New** window opens to the **Model** page, select an option:

- Click the **Model Wizard** button () to open the **Select Space Dimension** window. Go to [The Model Wizard](#) section to continue.
- Click the **Blank Model** button () to open COMSOL Multiphysics without any model set up in the Model Builder or return to the default COMSOL Desktop. You can then add components and physics interfaces to the model.

To enable the **Physics Builder** choose **Preferences** () from the **File** menu (Windows users) or from the **Options** menu (macOS and Linux users). Click **Physics Builder** and select the **Enable Physics Builder** check box.

After the applicable check box is selected, go to the **Model Wizard** and on the **New** page under **Physics**, click **Physics Builder** (). See the *Physics Builder Manual* for information.

The Model Wizard

The Model Wizard helps you build a model by choosing the space dimension, physics interfaces, and the study you want to use. In the Model Wizard you [Select Space Dimension](#), [Select Physics](#), [Review Physics Interface](#), and finally [Select Study](#).

SELECT SPACE DIMENSION

- 1 Open the Model Wizard (see [Open a New Window to Begin Modeling](#)).
- 2 On the **Select Space Dimension** page, click to choose the **Component** geometry dimension: **3D**, **2D axisymmetric**, **2D**, **1D axisymmetric**, **1D**, or **0D**.

Component Nodes by Space Dimension

The **Component** node has different icons based on space dimension **0D** (•) (no space dimension), **1D** (—), **1D axisymmetric** (🕒), **2D** (🕒), **2D axisymmetric** (🕒), and **3D** (cube).

	0D is used for interfaces modeling spatially homogeneous systems such as chemical reacting systems, electrical circuits, and general ODEs and DAEs. If you want to import a geometry, this is done in the Model Builder, but make sure you choose spatial dimensions that this geometry exists in. Remember, not all physics interfaces are available for all space dimensions.
--	---

	Also add a Component node to the Model Builder :
	<ul style="list-style-type: none">By right-clicking the Root node (🕒) and selecting it from the Add Component menu.
	<ul style="list-style-type: none">In the Home toolbar, select an option from Add Component list.

SELECT PHYSICS

On the **Select Physics** window, there are different ways to select one or several physics interfaces to add to the model. There are also interfaces for PDEs, ODEs, and DAEs, and other mathematical interfaces for equation-based modeling under the **Mathematics** branch.

Once one or more physics interfaces are selected, there are several options to continue; see [Figure 2-13](#). Click to select one of these buttons:

ICON AND NAME	ACTION
	Double-click to add the selected physics interface to the Added physics interfaces list, or right-click and select Add physics to add one or more selected physics interfaces. You can also add the selected physics by pressing Enter. Add as many physics interfaces as you want. You can use the Review Physics Interface page to edit the Dependent Variables as required. Click Remove as required to organize the physics interfaces in the list.
	Click to go back to the Select Space Dimension page.
	Click to choose the study for the model.
	Click to add the physics interface without a study.
	Click to return to the New page of the Model Wizard.
	Click to open the context-based Help window.

	You can also add physics interfaces from the Model Builder and The Add Physics Window :
	<ul style="list-style-type: none">In the Home toolbar, click the Add Physics button.By right-clicking the Component node and selecting Add Physics.

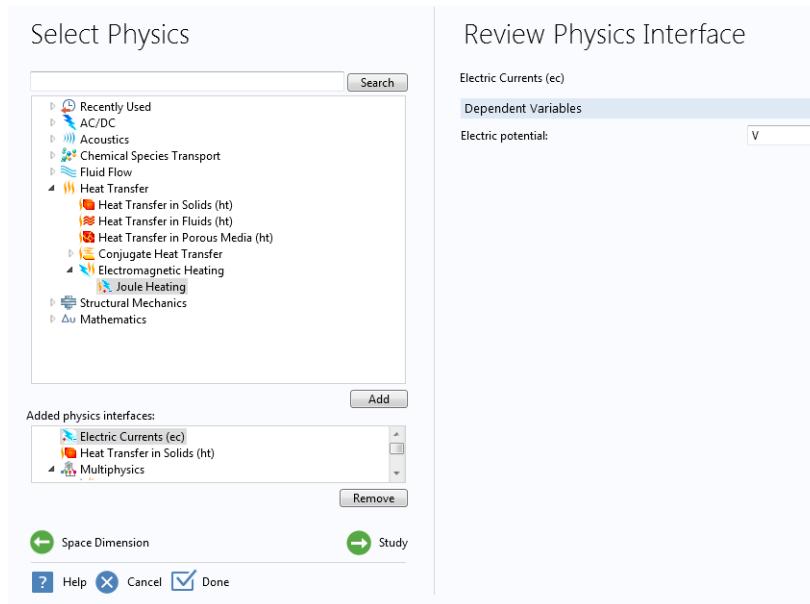

Figure 2-13: The Select Physics and Review Physics Interface windows in the Model Wizard.

REVIEW PHYSICS INTERFACE

Under **Added physics interfaces** (see Figure 2-13), click any interface to open the **Review Physics Interface** page. Here you can review and optionally modify any **Dependent Variables** names and, for some physics interfaces, specify the number of dependent variables. For other physics interfaces you can edit both the name of the field and the field components. Examples of fields with components are the displacement field in a Solid Mechanics interface and the Velocity field for a Laminar Flow interface.

To remove a physics interface already selected, highlight it in the list and click **Remove** under the table.

SELECT STUDY

On the **Select Study** page, click to select the type of study to perform. You can also double-click the study to select it and close the Model Wizard. The available options depend on the set of physics interfaces included in the model. Some study types are applicable to all physics interfaces for which you choose to solve, while others are not, but all are in some way available. The most applicable and common studies, such as **Stationary**, appear at the top of the list under **General Studies**. You can also select a study type from one of the following branches (see Figure 2-14):

- **General Studies** — General studies that are the most applicable for the selected physics interfaces.
- **Preset Studies for Selected Physics Interfaces** — Studies applicable to each physics interface that you have chosen to include. These preset studies appear under subnodes for each physics interface or under **Suggested by Some Physics Interfaces**.
- **Preset Studies for Selected Multiphysics** — Studies applicable to the multiphysics couplings that you have chosen to solve for.
- **More Studies** — Any fundamental study types (**Stationary**, **Time Dependent**, **Eigenfrequency**, **Eigenvalue** and **Frequency Domain**) that are not applicable to any of the physics interfaces being solved for. Also, this branch can contain some advanced composite study types.

- **Preset Studies for Some Physics Interfaces** — The study types recognized by some, but not all, of the physics interfaces being solved for.
- **Empty Study** — An empty study that will not perform any type of study unless you add some study steps to it.

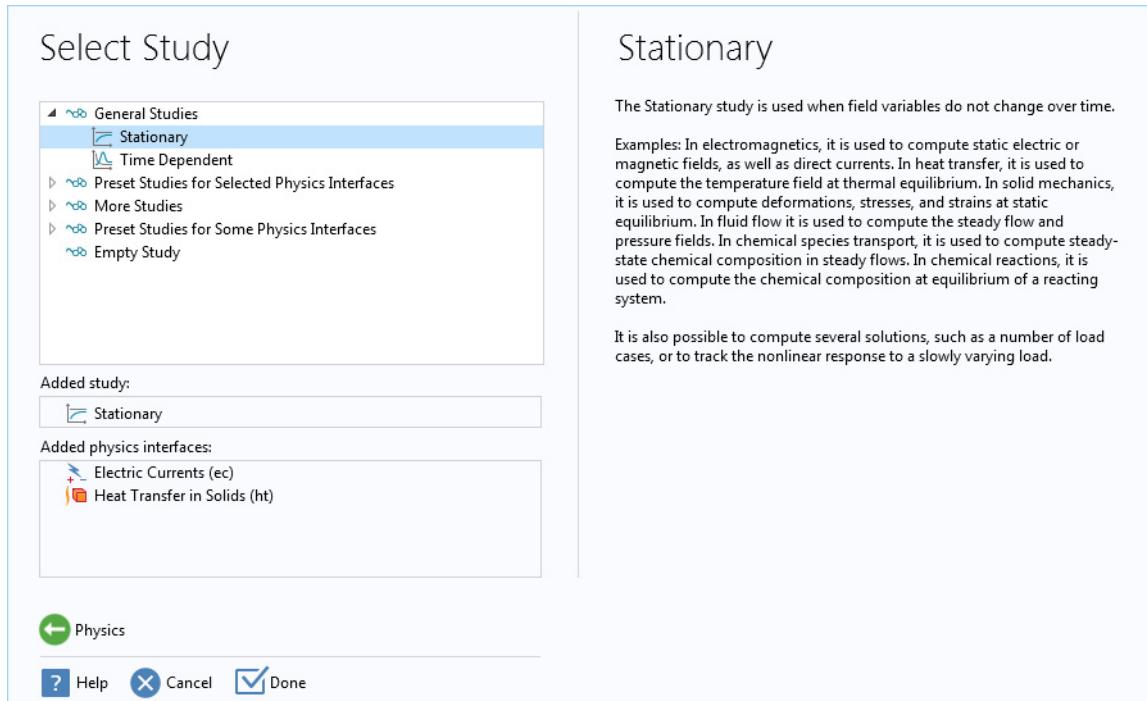

Figure 2-14: The Select Study page in the Model Wizard.

Once a study is highlighted, information about it displays to the right of the window and it is included under **Added study**. There are several options to continue.

ICON AND NAME	ACTION
Physics	Click to go back to the Select Physics and Review Physics Interface window.
Done	Click to exit the Model Wizard.
Cancel	Click to return to the New page of the Model Wizard.
Help	Click to open the context-based Help window.

	Also add physics interfaces from the Model Builder and The Add Physics Window :
	<ul style="list-style-type: none"> • In the Home toolbar, click the Add Physics button. • By right-clicking the Component node and selecting Add Physics.

After clicking **Done**, the **Model Builder** window displays a model tree with a set of default nodes in the **Component** branches: **Definitions**, **Geometry**, **Materials**, **Mesh**, and nodes based on the physics interfaces selected (see Figure 2-15). The **Component** nodes and branches form the sequence of operations that define the model.

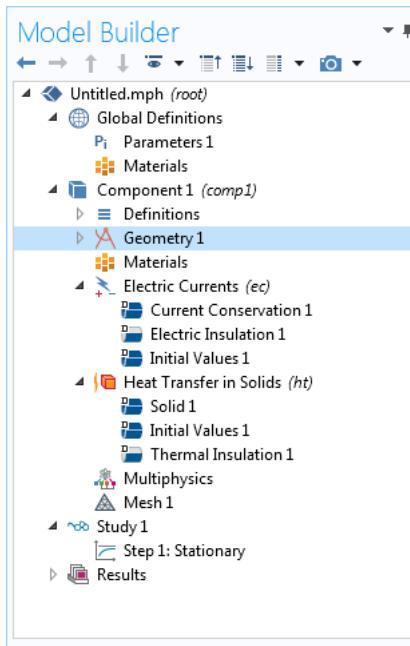

Figure 2-15: After clicking *Done*, a 3D Component with Electric Currents, Heat Transfer in Solids interfaces, and a Stationary study is added to the Model Builder.

	<p>Also add a study from the Model Builder and The Add Study Window:</p> <ul style="list-style-type: none"> • By right-clicking the Root node and selecting Add Study. • In the Home toolbar, click the Add Study button.
	<ul style="list-style-type: none"> • Building a COMSOL Multiphysics Model • The Component Node • The Add Physics Window • The Add Study Window • The Model Builder

Toolbars and Keyboard Shortcuts

The toolbars and context menus in COMSOL Multiphysics are based on the stage of modeling. This section is a single resource for each of the ribbon and contextual toolbars available on the COMSOL Desktop. There are also several [Keyboard Shortcuts](#) that are useful for navigating during the modeling process. The following sections have a table where there are links to more information about the available items in the ribbon toolbar or contextual toolbar.

- [Home Toolbar](#)
- [Definitions Toolbar](#)
- [Geometry Toolbar](#)
- [Work Plane Modal Toolbar](#)
- [Materials Toolbar](#)
- [Physics Toolbar](#)
- [0D Component Toolbar](#)
- [Mesh Toolbar](#)
- [Study Toolbar](#)
- [Results Toolbar](#)
- [Plot Group Contextual Toolbar](#)
- [Report Group Contextual Toolbar](#)
- [Template Group Contextual Toolbar](#)
- [View Toolbar](#)
- [Developer Toolbar](#)

[About Changes to the Ribbon Display \(Windows Users\)](#)

Home Toolbar

The **Home** ribbon toolbar (Windows) and the **Model Toolbar** (macOS and Linux) contains many of the common features and actions required to build and analyze a model.

For step-by-step instructions and general documentation descriptions, this is the **Home** toolbar.

TABLE 2-5: THE HOME TOOLBAR

	View ¹	Add a View node to the current Component to control the view and lighting in the Graphics window.  3D and  2D.	View (1D and 2D) , View (3D) , Axis (2D and 2D Axisymmetric) and Axis (1D and 1D Axisymmetric)

¹ For cross-platform users (macOS and Linux), the combination of buttons that display is dependent on the toolbar setting. For example, some buttons may not be visible if the Tools>Toolbar Display Mode is set to Normal and the Tools>Toolbar Button Label is set to Show Icon and Text. It also depends on whether you are using a Widescreen or Regular Screen Layout.

Geometry Toolbar

Once a geometry is added to the model, the **Geometry** ribbon toolbar (Windows) and the **Geometry** contextual toolbar (macOS and Linux) contains many of the common features and actions required to create and build a geometry.

For cross-platform users, some options listed in Table 2-7 are available from other toolbars and menus. Table 2-8 lists the geometry drawing tools available on the toolbars in 1D and 2D, as well as on the Work Plane toolbar for 3D models. See [Cross Platform \(macOS and Linux\) Toolbars and Menus](#).

	For step-by-step instructions and general documentation descriptions, this is the Geometry toolbar.
---	--

TABLE 2-7: THE GEOMETRY TOOLBARS

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS
Build 		
	Build All ²	Build all features in the current geometry. See Editing and Building Geometry Nodes .
Import/Export 		
	Import ²	Import the geometry from a COMSOL Multiphysics file or CAD file.
	Insert Sequence	Insert a geometry sequence from a COMSOL Multiphysics file into the current geometry. See Inserting a Sequence .
	Export	Export the current geometry as a COMSOL binary or text file or to a CAD file format. See Exporting a Geometry .

TABLE 2-7: THE GEOMETRY TOOLBARS

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS
Cleanup 		
 Defeaturing and Repair ^{1,3}	Defeaturing and Repair ^{1,3}	Choose from Cap Faces, Delete Fillets, Delete Short Edges, Delete Sliver Faces, Delete Small Faces, Delete Spikes, Delete Faces, Detach Faces, Knit to Solid, and Repair.
 Remove Details	Remove Details	Remove small details from 3D geometries. See Remove Details .
 Virtual Operations ¹	Virtual Operations ¹	Virtual geometry operations and mesh control operations. See Virtual Geometry Operations and Virtual Geometry and Mesh Control Operations .
Primitives  (3D)		
 Block	Block	Add a Block to the current geometry.
 Cone	Cone	Add a Cone to the current geometry.
 Cylinder	Cylinder	Add a Cylinder to the current geometry.
 Sphere	Sphere	Add a Sphere to the current geometry.
 Torus	Torus	Add a Torus to the current geometry.
 Helix	Helix	Add a Helix to the current geometry.
 More Primitives	More Primitives	Add all other primitives as in Table 7-1 and Geometric Primitives . Also see the geometry parts available in the Part Libraries.
Primitives  (2D)		
 Primitives	Primitives	The following are available from this menu: Circle , Ellipse , Rectangle , Square , Bézier Polygon , Interpolation Curve , Parametric Curve , Point , and Polygon . Also see Geometric Primitives and The Geometry Toolbar — Drawing Tools (Table 2-8) .
Primitives  (1D)		
 Interval	Interval	Draw an interval (line) in the Graphics window. For 1D models, first click the Interval button, then click the starting point and endpoint in the Graphics window. Also see Geometric Primitives and The Geometry Toolbar — Drawing Tools (Table 2-8) .
 Point	Point	Add a point to the Graphics window. Use this to draw a single point. First click the Point button, then click in the Graphics window (in 1D and 2D), or specify the point location in its Settings window. In 2D and 3D, this button is available on the More Primitives menu.
Work Plane 		
 Select Work Plane	Select Work Plane	Once Work Planes are available or added, these are listed here and you can click to take you to the associated Plane Geometry node in the Model Builder. It also opens a new Work Plane contextual toolbar for the Work Plane. See Using Work Planes , Work Plane Modal Toolbar and Table 2-8 .
 Work Plane	Work Plane	Add a Work Plane to the current geometry. See Using Work Planes , Work Plane Modal Toolbar and Table 2-8 .

TABLE 2-7: THE GEOMETRY TOOLBARS

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS
Operations 		
	Extrude	Extrude planar faces of geometry objects or objects from a work plane to create 3D geometry objects.
	Revolve	Revolve planar faces of geometry objects or objects from a work plane about an axis to create 3D geometry objects.
	Sweep	Sweep faces along a spine curve to create a solid object.
	Loft	Requires the Design Module. Lofting planar sections along a path.
	Booleans and Partitions	Create a geometry object using Boolean operations: Union , Intersection , Difference , and Compose . Partition geometry objects into parts using other geometry objects as tool objects for the partition. Alternatively, in 3D, use a work plane to partition the geometry objects. Select Partition Objects or Partition Edges .
	Transforms	This menu has these operations available: Array , Copy , Mirror , Move , Rotate ¹ , Scale ¹
	Conversions ¹	See Table 7-5 for a list of these features. Also see Conversion Operations .
	Chamfer ¹	Chamfer corners in 2D geometry objects. Also in 3D with the Design Module.
	Fillet ¹	Fillet corners in 2D geometry objects. Also in 3D with the Design Module.
	Tangent	Add a line segment that is tangent to a given edge in 2D geometries.
	Delete ¹	Delete the selected geometry objects. See Clearing Sequences and Deleting Sequences or Nodes .
	Edit Object	Adjust edges and vertices for 2D geometry objects or add or delete edges and vertices in the object.
	Cross Section	Create 2D cross sections from 3D geometries.
Other 		
	Parts	3D, 2D, and 1D Parts, Load Part, and Part Instances. See Part Libraries , Using Geometry Parts , and Part Instance .
	Programming ¹	If + End If and Parameter Check. From the Add Before and Add After menus: If, Else If, Else, and End If. See If , Else If , Else , End If , and Parameter Check .
	Selections ¹	Create named selections of geometry objects or geometric entities in geometry objects. See Creating Named Selections in the Geometry Sequence .
	Colors ¹	Add coloring to highlight named selections in the Graphics window. See Selection Colors .
	Measure ¹	Measure the volume, area, perimeter, or other geometric properties of the selected geometric entities or objects. See Measuring Geometry Objects .

TABLE 2-7: THE GEOMETRY TOOLBARS

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS
	Delete Sequence ¹	Delete a geometry sequence. See Clearing Sequences and Deleting Sequences or Nodes .

¹ For cross-platform users (macOS and Linux), the combination of buttons that display is dependent on the toolbar setting. For example, some buttons may not be visible if the Tools>Toolbar Display Mode is set to Normal and the Tools>Toolbar Button Label is set to Show Icon and Text. It also depends on whether you are using a Widescreen or Regular Screen Layout. It also depends if the button is available on the Work Plane toolbar, in which case it may be visible.

² For cross-platform users, this option is available from a different toolbar or menu. See [Cross Platform \(macOS and Linux\) Toolbars and Menus](#).

³ These features are available for the LiveLink and CAD products, and you must use the CAD kernel for the geometry representation.

GEOMETRY DRAWING TOOLBAR BUTTONS

In 1D and 2D there are buttons for drawing [Geometric Primitives](#) by using the mouse. In 3D, the buttons are available to create primitives, but you cannot draw these using the mouse unless you are using a Work Plane.

TABLE 2-8: THE GEOMETRY TOOLBAR — DRAWING TOOLS

BUTTON OR MENU	NAME	DESCRIPTION OR ACTION
Draw Settings		
	Snap to Grid (1D, 2D. and 2D axisymmetric)	Snap to the grid when drawing a geometry object in the Graphics window. By default, the mouse pointer snaps to the grid points. The active grid point for the snapping is indicated with a red circle. To disable snapping to the grid, click the Snap to Grid button.
	Snap to Geometry (1D, 2D. and 2D axisymmetric)	Snap to the vertices, centerpoints, and, in some cases, side midpoints of other geometry objects when drawing a geometry object in the Graphics window. By default, the mouse pointer snaps to the geometry vertices (for example, the corners of a rectangle). The active point for the snapping is indicated with a red circle. To disable snapping to the geometry objects, click the Snap to Geometry button.
	Solid (2D and 2D axisymmetric)	Create a solid (instead of a curve) when drawing a geometry object in the Graphics window. The Solid button is used to toggle between drawing solid objects or outlines (curves) and can be used in combination with all the draw buttons on the toolbar (for example, to draw squares, circles, and rectangles). It is selected by default to draw solid objects. When used to draw a polygon in combination with the Line, Quadratic, and Cubic operations, the solid object (or outline) displays once the object is closed or the points joined.
Draw (2D) 		
	Line	Draw line segments, quadratic curve segments, and cubic curve segments of a Bézier Polygon in the Graphics window.
	Quadratic	To draw a polygon consisting of line segments or Bézier curves first click one of these buttons. Then click the control points of the segments in the Graphics window. Click one point for each linear segment, two points for each quadratic segment, and three points for each cubic segment. If you want to switch segment type, click one of the buttons and then click some more control points. Close the polygon by right-clicking anywhere in the Graphics window. Then, a solid Bézier polygon appears, and a corresponding Bézier Polygon node appears in the geometry sequence. If you want to modify the polygon (for instance, change from solid to curve) you can edit the Bézier Polygon node by clicking it to display its Settings window.
	Cubic	

TABLE 2-8: THE GEOMETRY TOOLBAR — DRAWING TOOLS

BUTTON OR MENU	NAME	DESCRIPTION OR ACTION
.	Point	Add a Point to the Graphics window. Use this to draw a single point. First click the Point button, then click in the Graphics window (in 1D and 2D), or specify the point location in its Settings window. In 2D and 3D, this button is available on the More Primitives menu.
	Rectangle	To draw a Rectangle or Square select Rectangle, Square, Rectangle (Center), or Square (Center) from the menu. Then, click a corner (or the center) of the square or rectangle in the Graphics window. Drag the mouse to the desired position of a corner. When the mouse button is released, a square or rectangle appears and a Square or Rectangle node is added to the geometry sequence.
	Circle	To draw a Circle or Ellipse , select Circle, Ellipse, Circle (Corner), or Ellipse (Corner) from the menu. Then, click the center (or a corner of the bounding box) of the circle or ellipse in the Graphics window. Drag the mouse to the desired position of a corner of the bounding box. When the mouse button is released, a circle or ellipse appears and an Ellipse or Circle node is added to the geometry sequence.

Draw (ID) 

	Interval	Draw an Interval (line) in the Graphics window. For 1D models, first click the Interval button, then click the starting point and endpoint in the Graphics window.
.	Point	Add a Point to the Graphics window. Use this to draw a single point. First click the Point button, then click in the Graphics window (in 1D and 2D), or specify the point location in its Settings window. In 2D and 3D, this button is available on the More Primitives menu.

Work Plane Modal Toolbar

The **Work Plane** modal toolbar is available after clicking [Plane Geometry](#) under [Geometry>Work Plane](#) in the Model Builder.

	For step-by-step instructions and general documentation descriptions, this is the Work Plane modal toolbar.
	The Work Plane toolbar is similar to the 2D Geometry Toolbar except that the Virtual Operations menu is not available and there is a Close button.

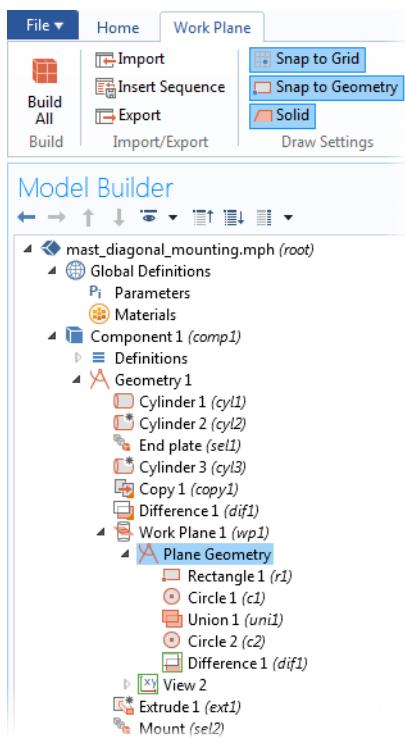

Figure 2-16: Click the **Plane Geometry** node to open the Work Plane toolbar.

Materials Toolbar

Once physics interfaces are added to the model, the **Materials** ribbon toolbar (Windows) and the **Materials** contextual toolbar (macOS and Linux) contains many of the common features and actions required to work with the features found under the **Materials** node in the Model Builder.

	For step-by-step instructions and general documentation descriptions, this is the Materials toolbar.
--	---

TABLE 2-9: THE MATERIALS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Materials			
	Add Material	Open the Add Material window to add materials to components or selections.	The Add Material Window
	Blank Material	Add a blank material to your model.	Materials and The Settings Window for Material
	Browse Materials	Open the Material Browser where you can access and edit material libraries.	The Material Browser Window
	More Materials	Add a Material Link, a Material Switch, or an External Material.	Material Link, Switch for Materials, and Working with External Materials

TABLE 2-9: THE MATERIALS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Property Groups			
	Analytic	Add an Analytic function node to define an analytic function.	Analytic and Using Functions in Materials
	Interpolation	Add an Interpolation function node to define an interpolation function.	Interpolation and Using Functions in Materials
	Piecewise	Add a Piecewise function node to define a piecewise function.	Piecewise and Using Functions in Materials
	User-Defined Property Group	Add a user-defined property group to current material.	Property Groups
User-Defined Libraries			
	Add to Library	Add a material to a user-defined material library.	User-Defined Materials and Libraries

Physics Toolbar

Once physics interfaces are added to the model, the **Physics** ribbon toolbar (Windows) and the **Physics** contextual toolbar (macOS and Linux) contains many of the common features and actions required to add physics interfaces and features to the Model Builder.

	For interfaces available in 0D, see 0D Component Toolbar .
	For step-by-step instructions and general documentation descriptions, this is the Physics toolbar.

TABLE 2-10: THE PHYSICS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Physics 			
—	Various - the physics interface name	Any physics interfaces added to the selected Component are listed. Click to go to the node in the Model Builder and open the Settings window. See Physics Interface Guide .	The Physics Interfaces
	Add Physics	Open the Add Physics window to add physics interfaces to the current component.	The Add Physics Window
	Add Multiphysics	Open the Add Multiphysics window to add applicable multiphysics couplings to the current component.	The Add Multiphysics Window
	Insert Physics from Model	Open the Insert Physics dialog box to insert physics interfaces in the current model component from another model file.	Adding and Inserting Physics Interfaces

TABLE 2-10: THE PHYSICS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Geometric Entity			
	Domains	See Table 3-3 for a list of all the icons by space dimension.	
	Boundaries	Available physics features for the physics interface are listed. To add subnodes, however, you need to right-click the parent node. For example, to add a Destination Selection subnode, right-click Periodic Condition.	
	Pairs		About Geometric Entities
	Edges		About Selecting Geometric Entities
	Points		
	Global		
Contextual 			
	Attributes	Subnodes that can be added to a main (parent) node.  0D,  1D,  2D, and  3D	For example, Destination Selection (a subnode to Periodic Condition) or Damping (a subnode to Linear Elastic Material). When available, Harmonic Perturbation is added from this menu as an exclusive node. See Harmonic Perturbation — Exclusive and Contributing Nodes
	Load Group	After adding a Load Group to the Global Definitions branch you can activate it in one or more load cases.	Using Load Cases
	Constraint Group	After adding a Constraint Group to the Global Definitions branch you can activate it in one or more load cases.	
	Harmonic Perturbation	Click this to add Harmonic Perturbation as a contributing node.	Harmonic Perturbation — Exclusive and Contributing Nodes
Multiphysics 			
	Multiphysics Couplings	This menu contains any physics features that provide multiphysics couplings likely to be used for the set of physics interfaces added to the Model Builder.	Multiphysics Modeling Approaches and The Multiphysics Branch

0D Component Toolbar

Once a 0D component interface is added to the model, a toolbar with the same name as the physics interface displays in the ribbon (Windows) and the contextual toolbar (macOS and Linux).

For step-by-step instructions and general documentation descriptions, the name of the toolbar is the same as the physics interface it is attached to.

These toolbars are documented for the interfaces in the applicable module documentation.

AVAILABLE WITH A COMSOL MULTIPHYSICS LICENSE:

- Global ODEs and DAEs. See [The Global ODEs and DAEs Interface](#).
- Events. See [The Events Interface](#).
- Sensitivity. See [The Sensitivity Interface](#).

AVAILABLE WITH THE ADDITION OF VARIOUS LICENSES:

- Reaction Engineering
- Chemistry
- Optimization

Mesh Toolbar

Once a mesh is added to the model, the **Mesh** ribbon toolbar (Windows) and the **Mesh** contextual toolbar (macOS and Linux) contains many of the common features and actions required to work with meshes.

TABLE 2-11: THE MESH TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Build			
	Build Mesh ²	Build the current mesh.	Adding, Editing, and Building Meshing Sequences
	Mesh (1, 2, 3,...)	Lists the meshes available in the model. Click a Mesh button to go to the node in the Model Builder.	Creating a Mesh for Analysis
	Add Mesh	Add a new mesh to the current model component.	Adding, Editing, and Building Meshing Sequences
Physics Controlled 			
	Edit	Edit the physics-controlled sequence.	Physics-Controlled Mesh
	Reset	Reset the sequence to the physics-controlled settings.	
	Mesh Size (Normal is the default)	See Table 8-1 for a list of options.	
Generators 			
	Free Tetrahedral	Generate unstructured tetrahedral mesh for 3D components.	Free Tetrahedral
	Swept	Generate swept mesh for 3D components.	Swept
	Boundary	The following are available from this menu: Free Triangular , Free Quad , Mapped , and Edge .	
	Boundary Layers	Generate boundary layer mesh.	Boundary Layers
Operations 			
	Modify	Size: Distribution and Corner Refinement Elements: Convert and Refine Mesh: Reference and Scale	Meshing Operations and Attributes and Mesh Attributes

TABLE 2-11: THE MESH TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
	Copy	Copy Domain, Copy Edge, Copy Face, and Copy.	Meshing Operations and Attributes
Attributes 			
	Mesh Size (Normal is the default)	See Table 8-1 for a list of options.	The Mesh Toolbar (Predefined Mesh Element Sizes) Mesh Element Quality and Size
	Distribution	Add a Distribution node under the selected node to specify an element distribution.	Mesh Attributes
	More Attributes	See Mesh Attributes.	
Import/Export 			
	Import	Import mesh.	Importing Meshes
	Partitions	Create geometric entities by partitioning the mesh. Ball, Box, Cylinder, Logical Expression, and Detect Faces.	Using Operations on an Imported Mesh
	Delete Entities	Delete geometric entities.	Using Operations on an Imported Mesh
	Join Entities	Join adjacent geometric entities.	Using Operations on an Imported Mesh
	Create Vertex	Create an additional vertex entity in the mesh.	Using Operations on an Imported Mesh
	Export	Export mesh.	Exporting Meshes
	Create Part	Create a Mesh Part node, under which you import a mesh and prepare it for use in a component.	Using Mesh Parts
	Create Geometry from Mesh	Create a new model component with a geometry created from the mesh.	Creating Geometry from Mesh
Evaluate 			
	Measure	Measure the volume, area, perimeter, or other geometric properties of the selected geometry objects.	Measuring Geometry Objects
	Statistics	Write information about number and quality of elements to the Messages window.	The Mesh Statistics Window
	Plot	Add a mesh plot.	Mesh (Plot)
Clear 			
	Clear Mesh ¹	Clear the mesh.	Clearing Sequences and Deleting Sequences or Nodes
	Clear All Meshes ¹	Clear all meshes in the model.	

TABLE 2-11: THE MESH TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
	Delete Sequence ¹	Delete a meshing sequence.	Clearing Sequences and Deleting Sequences or Nodes

¹ For cross-platform users (macOS and Linux), the combination of buttons that display is dependent on the toolbar setting. For example, some buttons may not be visible if the Tools>Toolbar Display Mode is set to Normal and the Tools>Toolbar Button Label is set to Show Icon and Text. It also depends on whether you are using a Widescreen or Regular Screen Layout.

² For cross-platform users, this option is available from a different toolbar or menu. See [Cross Platform \(macOS and Linux\) Toolbars and Menus](#).

Study Toolbar

The **Study** ribbon toolbar (Windows) and the **Study** contextual toolbar (macOS and Linux) contains many of the common features and actions required to work with studies and solvers.

	For step-by-step instructions and general documentation descriptions, this is the Study toolbar.
---	---

TABLE 2-12: THE STUDY TOOLBAR

BUTTON OR MENU	NAME	OPTIONS DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Study 			
=	Compute ¹	Compute the selected study.	Computing a Solution
	Select Study ¹	See a list of all available studies in Table 20-2 .	Study and Study Step Types
	Add Study ¹	Open the Add Study window to add a study to the current model component.	The Add Study Window
➡	Continue	Continue the computation of a solver sequence from the last computed feature.	The Progress Window
	Update Solution	Update the solution using the current values of parameters and user-defined variables.	Updating a Solution
	Get Initial Value	Generate a solution using the initial values of the dependent variables (without solving for the dependent variables).	Computing the Initial Values
Solver 			
	Show Default Solver	Display the nodes in the solver sequences that are created by default.	Show Default Solver
Study Step 			
	Study Steps	See lists of all available study types and study steps in Table 20-2 and Table 20-3 .	The Add Study Window and The Relationship Between Study Steps and Solver Configurations
	Parametric Sweep	Choose Parametric Sweep or Optimization, for example.	Study Extension Steps and Advanced Study Extension Steps
	Function Sweep	Run a function sweep, switching between different user-defined functions.	Function Sweep

TABLE 2-12: THE STUDY TOOLBAR

BUTTON OR MENU	NAME	OPTIONS DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
	Material Sweep	Run a material sweep, switching between different materials.	Material Sweep
	Combine Solutions	Combine solutions using concatenation or summation, or by removing solutions.	Combine Solutions
	Study Reference	Add a study step that refers to another study.	Study Reference
	Optimization	Perform an optimization study. This is available with the addition of the Optimization Module.	See the <i>Optimization Module User's Guide</i> .
	Parameter Estimation	Perform a parameter estimation study. This is available with the addition of the Optimization Module.	See the <i>Optimization Module User's Guide</i> .

Operations

	Create Solution Copy	Make a copy of a solution.	Solution Operation Nodes and Solvers
--	----------------------	----------------------------	--

Evaluate

	Statistics	Display statistics for the study, including the number of degrees of freedom (DOFs).	The Statistics Page
--	------------	--	-------------------------------------

Clear

	Clear Solutions	Clear the solutions in the current solver sequence.	Clearing Sequences and Deleting Sequences or Nodes
	Clear All Solutions	Clear all solutions.	

¹ For cross-platform users, this option is available from a different toolbar or menu. See [Cross Platform \(macOS and Linux\) Toolbars and Menus](#).

Results Toolbar

The **Results** ribbon toolbar (Windows) and the **Results** contextual toolbar (macOS and Linux) contains many of the common features and actions required to work with studies and solvers.

	For step-by-step instructions and general documentation descriptions, this is the Results toolbar.
--	---

TABLE 2-13: THE RESULTS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
	Plot	Plot the selected plot group.	Plot Groups and Plots . Also see Plot Group Contextual Toolbar .

TABLE 2-13: THE RESULTS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
—	Select Plot Group	Choose from a list of plots included in the model.	About Plot Groups . Also see Plot Group Contextual Toolbar .
	3D Plot Group	Create a new 3D Plot Group for 3D plots such as volume and slice plots.	
	2D Plot Group	Create a new 2D Plot Group for 2D plots such as surface and contour plots.	
	ID Plot Group	Create a new ID Plot Group for 1D graph plots.	
	Polar Plot Group	Create a new Polar Plot Group for graph plots in a polar coordinate system.	

Definitions 

	Parameters	Add a Parameters node under Results for defining results parameters.	Parameters
---	------------	--	----------------------------

Data Set 

	Cut Plane	Create a Cut Plane data set for data on a plane in 3D.	Cut Plane
	Cut Line 3D	Create a 3D Cut Line data set for data along a line in 3D.	Cut Line 2D and Cut Line 3D
	Cut Point 3D	Create a 3D Cut Point data set for data at a point in 3D.	Cut Point 1D, Cut Point 2D, and Cut Point 3D
	Cut Line 2D	Create a 2D Cut Line data set for data along a line in 2D.	Cut Line 2D and Cut Line 3D
	Cut Point 2D	Create a 2D Cut Point data set for data at a point in 2D.	Cut Point 1D, Cut Point 2D, and Cut Point 3D
	More Data Sets	See Table 21-7 for a list of all data sets.	Data Sets
	Selection (under Attributes)	Add a selection to the current data set.	Adding a Selection to a Data Set and Creating Named Selections
	Remesh Deformed Configuration (under Attributes)	Create a deformed geometry from a current data set.	Deformed Configuration

Numerical 

	Evaluate All	Evaluate all derived values and evaluation groups.	Table Window toolbar and Menu Options
	Clear and Evaluate All	Clear all current table entries and then evaluate all derived values and evaluation groups.	Table Window toolbar and Menu Options
	Evaluation Group	Add an Evaluation Group node to evaluate derived values and present them in an Evaluation Group table.	About Evaluation Groups
	Point Evaluation	Add a Point Evaluation node to evaluate some expressions or variables at points.	Point Evaluation

TABLE 2-13: THE RESULTS TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
	Global Evaluation	Add a Global Evaluation node to evaluate some global expressions or variables.	Global Evaluation
	More Derived Values	See Table 21-9 for a list of all derived value types.	Derived Values, Evaluation Groups, and Tables
	Table	Add a table.	Derived Values, Evaluation Groups, and Tables

Export

	Data ¹	Data, Plot, Mesh (Export), Table	Exporting Data and Images
	Image ¹	1D Image, 2D Image, or 3D Image	
	Animation	Animation or Player (see Animation) Create a movie to animate a solution (as an animated GIF, Flash, AVI, or WebM movie file, an image sequence, or as a player directly in the COMSOL Desktop Graphics window).	

Report

	Report ¹	Choose a Brief Report, Intermediate Report, Complete Report, Custom Report, Documentation, or create or choose a custom report template.	Creating, Exporting, and Using Custom Report Templates
--	---------------------	--	--

Clear

	Clear Plot Data ¹	Clear all plot data that is stored in the model.	Saving Plot Data in the Model
¹ For cross-platform users (macOS and Linux), the combination of buttons that display is dependent on the toolbar setting. For example, some buttons may not be visible if the Tools>Toolbar Display Mode is set to Normal and the Tools>Toolbar Button Label is set to Show Icon and Text. It also depends on whether you are using a Widescreen or Regular Screen Layout.			

Plot Group Contextual Toolbar

The plot group contextual toolbar is available after clicking a specific plot group in the Model Builder. The available tools are based on the model and the type of plot.

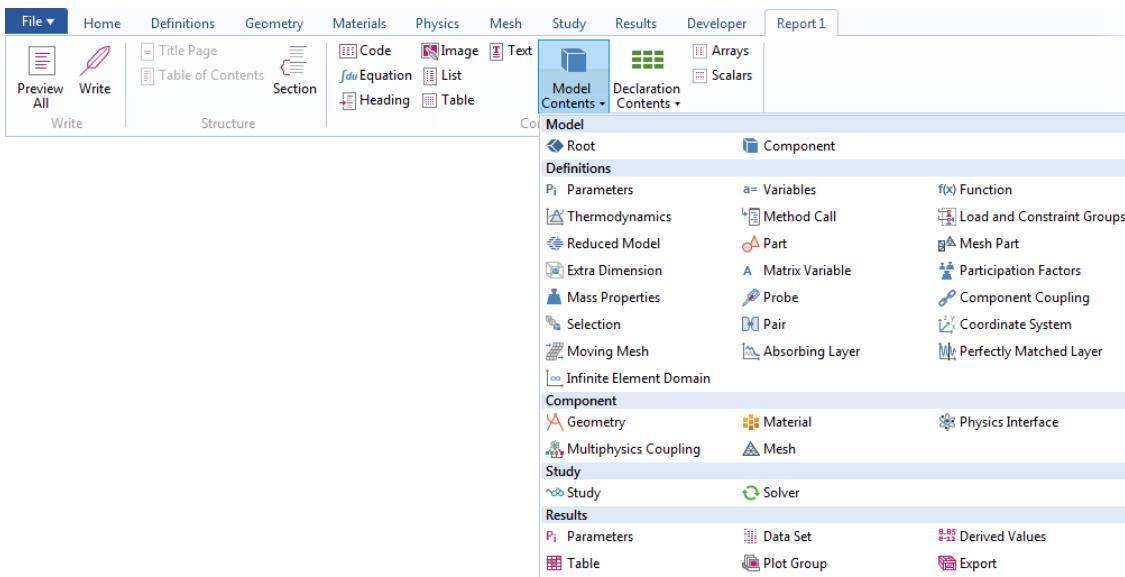

For step-by-step instructions and general documentation descriptions, this is generally referred to as the **Plot Group** toolbar, where the name of the toolbar changes based on the plot group (3D Plot Group, 2D Plot Group, 1D Plot Group, or Polar Plot Group). If the plot group is renamed, the toolbar name also changes to match the new name, as in the example above where the **3D Plot Group** toolbar was renamed **Stress (solid)**.

TABLE 2-14: THE PLOT GROUP CONTEXTUAL TOOLBAR

BUTTON OR MENU	NAME	LINK TO MORE INFORMATION

	Plot	Plot Groups and Plots
	Plot In New Window	The Plot Windows
Add Plot 		
Various	See Table 21-10 for the available plots by Plot Group (3D, 2D, 1D, or Polar Plot Groups).	About Plot Groups
Attributes 		
	Add a Color Expression to the currently selected plot.	Color Expression
	Add a Deformation to the currently selected plot.	Deformation
	Add a Filter to the currently selected plot.	Filter
	Add a Height Expression to the currently selected plot. This is for 2D plots.	Height Expression
Select  (available for creating cross-section plots)		
Various	See Table 21-11 for a list of the available buttons.	Creating Cross-Section Plots and Combining Plots and Plotting and Cross-Section Interactive Toolbar
Export 		
Various	See Table 21-12 for a list of export options.	Exporting Data and Images

Report Group Contextual Toolbar

The report group contextual toolbar is available after clicking a **Report** node in the Model Builder. It contains tools for creating a model report.

For step-by-step instructions and general documentation descriptions, this is generally referred to as the **Report Group** toolbar, where the name of the toolbar name changes based on the report group. If the report group is renamed, the toolbar name also changes to match the new name.

View Toolbar

Once physics interfaces are added to the model, the **View** ribbon toolbar (Windows) and the **View** contextual toolbar (macOS and Linux) contains many of the common features and actions required to work with the features found under the Materials node in the Model Builder.

For step-by-step instructions and general documentation descriptions, this is the **View** toolbar.

TABLE 2-17: THE VIEW TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Reset View			
	Reset to Default	Restore the default settings for the View node.	User-Defined Views
Lights (3D only)			
	Directional Light	Add a Directional Light to the View.	About the 3D View Light Sources and Attributes
	Point Light	Add a Point Light to the View.	
	Spotlight	Add a Spotlight to the View.	
	Headlight	Add a Headlight to the View.	
Hide			
	Hide	Add a selection feature to hide geometry objects or entities.	Hide for Geometry, Hide for Physics, Hide for Mesh Import

Developer Toolbar

For creating and running methods, adding method calls and settings forms to the Model Builder, and testing applications, the **Developer** ribbon toolbar is available in the Windows version. Some of the functionality is connected to the Application Builder and the creation and testing of apps, but you can also create model methods and method calls and run them for custom extensions of a model created in the Model Builder and also add custom settings form for custom settings to control the workflow in the Model Builder.

TABLE 2-18: THE DEVELOPER TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Application A			
	Application Builder (Ctrl+Alt+A)	Toggle between the Application Builder and Model Builder windows.	
	Data Access	Add data and properties that can be modified from a running application.	Data Access in the Application Builder Reference Manual.
	Test Application (Ctrl+F8)	Launch the application in a separate window.	Testing the Application in the Application Builder Reference Manual.
Create Methods			
	New Method	Create a new method with code to run in the model.	Creating and Running Methods in Models . Also see Creating Methods in the Application Builder Reference Manual .
	Record Method	Record changes to the embedded model to a new application method or model method.	Recording Code in the Application Builder Reference Manual .

TABLE 2-18: THE DEVELOPER TOOLBAR

BUTTON OR MENU	NAME	DESCRIPTION OR OPTIONS	LINK TO MORE INFORMATION
Method Calls			
▶	Method Call	Add any available model method as a method call in the Model Builder.	Method Calls
Run Methods			
	Run Method	Run one of the available methods.	Creating and Running Methods in Models
	Run Method Call	Run one of the added method calls.	
	Stop	Stop a running method.	
Forms			
	Settings Form	Add a form as a Settings window in the Model Builder.	Creating and Using Settings Forms and Dialogs
	Update Forms	Update forms in the Model Builder	
	Show Dialog	Show the form as a dialog box.	
Compare			
	Compare	Compare the current model and application with another MPH-file on the file system and then open the Comparison Result window.	Comparing Models and Applications

Keyboard Shortcuts

The following table summarizes the available keyboard shortcuts on Windows and Linux and on macOS (see also the Application Builder documentation for specific keyboard shortcuts):

SHORTCUT (WINDOWS, LINUX)	SHORTCUT (MACOS)	ACTION
F1	F1	Display help for the selected node or window.
Ctrl+F1	Command+F1	Open the COMSOL Documentation front page in an external Help window.
F2	F2	Rename the selected node, file, or folder.
F3	F3	Disable selected nodes.
F4	F4	Enable selected nodes.
F5	F5	Update solution with respect to new definitions without re-solving the model. Update reduced model data. Also, on Windows, to continue in the Method Editor's debugging tool in the Application Builder.
F6	F6	Build the preceding node in the Geometry branch or plot the previous plot for a time-dependent, eigenfrequency, or eigenvalue solution. Also, on Windows, to step in the Method Editor's debugging tool in the Application Builder,

SHORTCUT (WINDOWS, LINUX)	SHORTCUT (MACOS)	ACTION
F7	F7	Build the selected node in the geometry and mesh branches, compute the selected study step, compute to the selected node in the solver sequence, or plot the next plot for a time-dependent, eigenfrequency, or eigenvalue solution. Also, on Windows, to step into in the Method Editor's debugging tool in the Application Builder.
F8	F8	Build the geometry, build the mesh, compute entire solver sequence, update results data, update the plot, or run model method in a method call.
Del	Del	Delete selected nodes and selected geometry objects.
Left arrow (Windows); Shift + left arrow (Linux)	Left arrow	If you are at the top of a branch, pressing this collapses this branch in the Model Builder. Continue pressing the left arrow key to move upward in the tree to collapse all branches. If within a subbranch, pressing the left arrow key repositions you to the beginning of the branch.
Right arrow (Windows); Shift + right arrow (Linux)	Right arrow	Expand a branch in the Model Builder.
Up arrow	Up arrow	Move to the node above in the Model Builder.
Down arrow	Down arrow	Move to the node below in the Model Builder.
Alt+left arrow	Ctrl+left arrow	Move to the previously selected node in the Model Builder.
Alt+right arrow	Ctrl+right arrow	Move to the next selected node in the Model Builder.
Ctrl+A	Command+A	Select all domains, boundaries, edges, or points; select all cells in a table or all contents of a table cell.
Ctrl+C	Command+C	Copy text in fields. Copy images in graphics and plot windows.
Ctrl+D	Command+D	Clear the selection of all domains, boundaries, edges, or points in the Model Builder. Clear all selections in form editor windows.
Ctrl+Shift+D	Command+Shift+D	Duplicate the selected node in the Model Builder.
Ctrl+F	Command+F	Find a search string in a model or application method.
Ctrl+G	Command+G	Group nodes.
Ctrl+Shift+G	Command+Shift+G	Ungroup nodes.
Ctrl+K		Create, use, or rename a shortcut to an Model Builder node (for use in the Application Builder).
Ctrl+N	Command+N	Create a new model.
Ctrl+O	Command+O	Open a model file.
Ctrl+P	Command+P	Print the contents of the plot window.
Ctrl+S	Command+S	Save a model file.
Ctrl+V	Command+V	Paste copied text.
Ctrl+Y	Ctrl+Shift+Z	Redo the last undone operation.
Ctrl+Z	Command+Z	Undo the last operation.
Ctrl+I		Create a local variable or correct the type of an existing variable in methods.
Ctrl+7		Toggle comments on and off in methods.

SHORTCUT (WINDOWS, LINUX)	SHORTCUT (MACOS)	ACTION
Ctrl+up arrow	Command+up arrow	Move a definitions node, geometry node, physics interface or feature node (except default nodes), material node, mesh node, study step node, or results node up one step.
Ctrl+down arrow	Command+down arrow	Move a definitions node, geometry node, physics interface or feature node (except default nodes), material node, mesh node, study step node, or results node down one step.
Ctrl+Tab	Ctrl+Tab	Switch focus to the next window on the desktop.
Ctrl+Shift+Tab	Ctrl+Shift+Tab	Switch focus to the previous window on the desktop.
Ctrl+Alt+A		Switch to the Application Builder window from the Model Builder.
Ctrl+Alt+M		Switch to the Model Builder window from the Application Builder.
Ctrl+F4	Command+W	Close the active window in COMSOL Desktop, if it is closable.
Ctrl+F8		Test an application.
Ctrl+Alt+left arrow	Command+Alt+left arrow	Switch focus to the Model Builder window.
Ctrl+Alt+right arrow	Command+Alt+right arrow	Switch focus to the Settings window.
Ctrl+Alt+up arrow	Command+Alt+up arrow	Switch focus to the previous section in the Settings window.
Ctrl+Alt+down arrow	Command+Alt+down arrow	Switch focus to the next section in the Settings window.
Shift+F10 or (Windows only) Menu key	Ctrl+F10	Open the context menu.
Ctrl+Pause	Command+. (Command + period)	Stop running a method when test running applications.
Ctrl+Space, Ctrl+/-	Ctrl+Space, Ctrl+/-	Open list of predefined quantities for insertion in Expression fields.
+, -	+, -	Highlight the next or previous entity for a 3D geometry in the Graphics window.
R	R	Toggle between automatic and manual rotation center for mouse rotation in 3D.
X, Y, Z	X, Y, Z	Press to force rotation around the x, y, or z axis, respectively, when you move the mouse in 3D.

Building a COMSOL Multiphysics Model

This chapter explains a range of methods and topics used when building models in COMSOL Multiphysics®: From working with the Model Builder and fundamental concepts for building a model to the use of units. For examples of how to build a complete model and application step by step, see the application libraries for COMSOL Multiphysics and the add-on modules.

In this chapter:

Building Models in the Model Builder

The power of COMSOL Multiphysics is the ease of working with all the features and functionality required to build a model in The Model Builder. The sections [About the Sequence of Operations](#), [The Component Node](#), [Branches and Subbranches in the Tree Structure](#), [Settings and Properties Windows for Feature Nodes](#), and [Opening Context Menus and Adding Nodes](#) further introduce you to key concepts about navigating in the Model Builder, the structure of the tree, and how to add features (nodes) as you build your model.

The physics feature nodes that are added to physics interfaces are flexible and several sections describe the ways to identify changes, status updates, and other ways to work with these nodes: [The Physics Nodes](#), [Physics Interface Default Nodes](#), [Physics Feature Nodes by Space Dimension](#), [Physics Interface Node Context Menu Layout](#), [Physics Exclusive and Contributing Node Types](#), [Physics Node Status](#), [Dynamic Nodes in the Model Builder](#), and [Errors and Warnings](#).

- [The Root Settings and Properties Windows](#)
- [Creating a New Model](#)
- [The COMSOL Desktop](#)

The Model Builder

The modeling procedure is controlled through the **Model Builder** window, which is essentially a *model tree* with all the functionality and operations for building and solving models and displaying the results. These are introduced to your modeling procedure by adding a *branch*, such as the Geometry branch. Branches can have further *nodes* (or *subbranches*) that relate to their parent node. It is all [About the Sequence of Operations](#). See [Figure 3-2](#) for an example.

A node has its own properties and *Settings* window that are characteristic to it. Branches and subbranches can also contain properties and settings. See [Branches and Subbranches in the Tree Structure](#) and [Settings and Properties Windows for Feature Nodes](#) for examples.

The Model Builder has many types of nodes to help you create models and visualize the model structure — for example, the Component node is categorized by space dimension, and nodes are dynamic, which helps you identify nodes that change status. See [Component Nodes by Space Dimension](#), [Physics Interface Default Nodes](#), and [Dynamic Nodes in the Model Builder](#) for more information.

Also learn about the context menu available when you right-click a node in the Model Builder ([Opening Context Menus and Adding Nodes](#)). In the next section ([Working with Nodes in the Model Builder](#)), there is also information about [Going to the Source Node](#), [Copying, Pasting, and Duplicating Nodes](#), [Undoing and Redoing Operations](#), [Clearing Sequences and Deleting Sequences or Nodes](#), and [Disabling or Enabling Nodes](#).

- [The Root Settings and Properties Windows](#)
- [Creating a New Model](#)
- [Basic Navigation](#)
- [The COMSOL Desktop](#)

About the Sequence of Operations

COMSOL Multiphysics operates through *sequencing* and evaluates most of the branch nodes in the Model Builder from the top down as a *sequence of operations*. By adding nodes to a branch in the Model Builder in a certain order, you set up such sequences of operations, which makes it possible to, for example, parameterize a model and rerun the simulation. COMSOL Multiphysics then reevaluates each sequence, automatically updating the geometry, mesh, physics interfaces and features, and solution. A solver sequence, for example, could define your model with one solver and then, using the returned solution, solve it with an alternative solver.

For most sequences, you run the sequence by right-clicking the top node of the branch and selecting **Build All** (geometry) and **Build** (mesh), **Compute** (studies), or **Plot** (plot groups), or by pressing F8. These buttons are also on the **Settings** window and in the respective toolbars.

Some nodes under a physics interface branch can override other nodes higher up in the sequence. How the COMSOL Multiphysics software treats those nodes depends on whether they are contributing or exclusive nodes (see [Physics Exclusive and Contributing Node Types](#)).

The sequence of operations means that the order of the nodes in the tree is important. In the following branches of the model tree, the node order makes a difference, and you can move nodes up and down to change the sequence of operations for these nodes: Geometry, Material, physics interfaces and features, Mesh, and Solver.

Also, the order can have some importance in the plot groups in the Results branch and also for the [Perfectly Matched Layer](#) and [Infinite Element Domain](#) nodes in the Definitions branch (those nodes are available with some of the add-on modules).

- [Physics Node Status](#)
- [Physics Exclusive and Contributing Node Types](#)
- [Creating a Geometry for Analysis and Working with Geometry Sequences](#)
- [Moving Nodes in the Model Builder](#)

The Global Definitions Node

Under the **Global Definitions** node () you can add functionality that is global and applies to the entire mode. Right-click the **Global Definitions** node to add global parameters, variables and variable utilities, user-defined functions, load groups, constraint groups, global materials, common model inputs, and more. See [Global Definitions](#).

The Component Node

A model component is a fundamental part of the model and contains a geometry with its associated physics interface, mesh, and variables and other definitions that are local to that component. The **Component** node defines the namespace for each part of a model that is defined in a model component. A model can have several **Component** nodes. For example, if you are setting up a system model using both a 2D simplification — represented in one 2D **Component** branch — and a full 3D description in another **Component**, these can both be added to the Model

Builder to represent different aspects or parts of the model. You can couple variables between different components in a model using coupling operators.

To **Add Physics** and **Add Mesh** to the Component, from the **Home** toolbar, or for any operating system, right-click the **Component** node. See [The Add Physics Window](#), and [Creating a Mesh for Analysis](#) for more information.

The **Component** node icon also indicates the space dimension:..

TABLE 3-I: SPACE DIMENSION ICONS IN THE MODEL BUILDER

ICON	SPACE DIMENSION
	3D
	2D axisymmetric
	2D
	1D axisymmetric
	1D
	0D (space-independent models for chemical reactions and other ODEs and DAEs)

ADDING A COMPONENT TO A MODEL

You can create models with multiple geometries by adding one or more **Component** nodes to the Model Builder. Typically a component is added to the model in the Model Wizard when you select a space dimension.

To add a **Component** node or nodes:

- Right-click the **Root** node (the topmost node) in the **Model Builder** and select **Add Component** (see [The Root Settings and Properties Windows](#)).
- In [The Model Wizard](#) on the **Select Space Dimension** page, select **3D**, **2D axisymmetric**, **2D**, **1D axisymmetric**, or **1D**. Continue defining the model as in [Creating a New Model](#).

COPYING, PASTING, AND INSERTING COMPONENTS

You can copy and paste model components within a COMSOL Multiphysics session and also between COMSOL Multiphysics sessions, as long as the copied component information remains in the clipboard.

To copy a component with all its subnodes, right-click the **Component** node and choose **Copy** (or, for Windows users, click **Copy** on the Quick Access Toolbar). You can then paste it in the same or a new COMSOL Desktop session by right-clicking the root node and choosing **Paste Multiple Items** (or, for Windows users, click **Paste Multiple Items** on the Quick Access Toolbar).

It is also possible to insert components from another COMSOL Multiphysics model. To do so, right-click the top node (root node) and choose **Insert Components from Model**. An **Insert Components** dialog box appears where you can browse or type the path and name of the COMSOL Multiphysics model file from which you want to insert components in the **Model** field. Select one or more of the components in the model from the **Components** list and then click **OK** to insert them into the current model.

Some aspects when inserting or pasting a component into an existing model:

- Existing components in the open model may conflict with the inserted ones. In such cases, the inserted component will be renamed (for example, from `comp1` to `comp2`). Because inserting a component also inserts

many other nodes (geometry, physics, materials, coordinate systems, and so on), these will also be renamed if there are existing ones in the open model.

- Most of the nodes under a component only requires that the other nodes under the same component is inserted with them. However, there are some situations when items outside the component must be included. Especially, the geometry sequence depends on such items. When inserting or pasting a component, the process automatically includes necessary global parameters, global functions, and geometry parts. It will not include references to items in other components.
- File references are inserted as is, and no attempt is made to check if the file exists. When inserting or pasting a component, the process does not include stored files but rely on the original file path to be valid.
- Global parameters, global variables, and global functions in variable expressions (either in other variables or in physics settings) will not be inserted or pasted automatically.
- Deformed geometries and their associated meshes are not included in the insertion or paste operation. These geometries and meshes are typically the result of computing a solution and contain binary data that is not included in the insertion either. They should appear again after re-solving, which you need to do after the insertion anyway.

Altogether, these aspects may cause an insert or paste operation to be incomplete to some degree. In some cases, the difference is reported in a message dialog box after the insertion process has finished. Click **Cancel** in this dialog box to revert the insertion process.

THE DEFAULT NODES

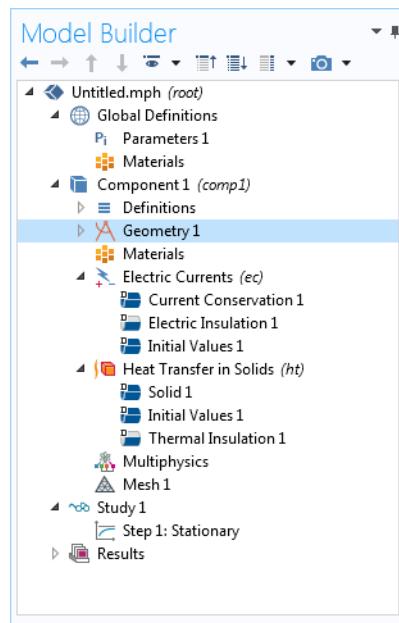

Figure 3-1: An example of the Model Builder default nodes for the Electric Currents and Heat Transfer in Solids interfaces.

These default nodes are normally added under a **Component** node:

- **Definitions:** Contains user-defined variables, selections, views, pairs, functions, probes, component couplings, and coordinate systems, which are defined locally for the model. See [Global Definitions](#), [Geometry](#), [Mesh](#), and [Materials](#) for information about using these local **Definitions** (≡) and **Global Definitions** (≡). Use [Global](#)

Definitions to define **Parameters**, **Variables**, **Functions**, and loads and constraint groups with a global scope — that is, groups that are not specific to one **Component** node.

- **Geometry** (): Contains the sequence of geometric objects and operations (or imported CAD data) that defines the model geometry.
- **Materials** (): Contains the materials and material properties used as sources for material data in the component. See [Materials](#) for detailed information.
- **Physics interfaces** (): Any added physics interface displays as a node under **Component** (**Solid Mechanics** in [Figure 3-1](#) for example).
- **Multiphysics** (): When a multiphysics interface is added to the Model Builder, this node contains all the relevant multiphysics coupling features for that interface. See [Multiphysics Modeling Approaches](#) for more information.
- **Meshes** (): Contains the sequences of meshing operations that defines the computational meshes for the model. When there is only one mesh in the model, its **Mesh** node appears directly under the **Component** node.

Branches and Subbranches in the Tree Structure

The **Settings** window has the following sections (also see [Figure 3-3](#)):

The label appears on the node as the default node name. The default label is Component 1, but you can change it in the **Label** field.

The name is a string used to define a namespace for the model component and identify variables defined in that component. The default component name is `comp1`, `comp2`, and so on, but you can change it in the **Name** field. See [Settings and Properties Windows for Feature Nodes](#) and [Displaying Node Names, Tags, and Types in the Model Builder](#) for more information.

GENERAL

This section contains general settings that you normally do not need to change:

Unit System

The default setting in the **Unit system** list, **Same as global system**, is to use the global unit system, which you specify in the root node's **Settings** window. If you want to use another unit system in a model, select it from this list.

Underneath, you can define the coordinates for the frames in a model if you do not want to keep the default names. All frames are always defined. See [About Frames](#) for more information about frames.

Spatial frame coordinates

For **Spatial frame coordinates**, the default names are x , y , and z for 3D as well as planar 1D and 2D geometries. For axisymmetric geometries, the default names for the spatial frame coordinates are r , φ (**phi**), and z . If you use the geometry to represent something other than space, or if you for some other reason want to use other names for the spatial coordinates, you can change the names in the fields for the **First**, **Second**, and **Third** coordinate under **Spatial frame coordinates**.

Material frame coordinates

For **Material frame coordinates**, the default names are X , Y , and Z for 3D as well as planar 1D and 2D geometries. For axisymmetric geometries, the default names for the material frame coordinates are R , φ (**PHI**), and Z . You can change the names in the fields for the **First**, **Second**, and **Third** coordinate under **Material frame coordinates**.

Geometry frame coordinates

For **Geometry frame coordinates**, the default names are X_g , Y_g , and Z_g for 3D as well as planar 1D and 2D geometries. For axisymmetric geometries, the default names for the geometry frame coordinates are R_g , φ_g (**PHIg**),

and Z_g . You can change the names in the fields for the **First**, **Second**, and **Third** coordinate under **Geometry frame coordinates**.

Mesh frame coordinates

For **Mesh frame coordinates**, the default names are X_m , Y_m , and Z_m for 3D as well as planar 1D and 2D geometries. For axisymmetric geometries, the default names for the mesh frame coordinates are R_m , φ_m (**PHIm**), and Z_m . You can change the names in the fields for the **First**, **Second**, and **Third** coordinate under **Mesh frame coordinates**.

You cannot use the variable for the time, t , as a frame coordinate name.

Geometry Shape Order

The setting in the **Geometry shape order** list determines the order of the curved mesh elements that determine the geometry shape. The default setting is **Automatic**, but it is also possible to select an order such as **Linear**, **Quadratic**, **Cubic**, **Quartic**, **Quintic**, **Sextic**, and **Septic**. The default setting allows for automatic reduction of the order in some cases.

- [Creating a New Model](#)
- [The Root Settings and Properties Windows](#)
- [Editing Node Properties, Names, and Labels](#)
- [About Frames](#)
- [Setting the Unit System for Models](#)
- [Using Extra Dimensions](#)
- [Curved Mesh Elements](#)

Adding Extra Dimensions to a Model

To add an extra, abstract spatial dimension to a model, right-click the **Global Definitions** node (🌐), and then from the **Extra Dimensions** context menu, choose **3D**, **2D Axisymmetric**, **2D**, **ID Axisymmetric**, or **ID** to add an extra dimension to the selected space dimension (requires that **Advanced Physics Options** is active in the **Show** menu). An **Extra Dimension** node, in the chosen space dimension, is then added under the **Global Definitions** node in the Model Builder. You can add one or several **Extra Dimension** nodes. It is also possible to attach an extra dimension to several components. Extra dimensions can be useful, for example, to model transport and reactions in two different scales, where one scale is the homogenized scale of a set of larger pores between particles or larger cracks in rocks, and a second smaller scale is the one inside porous particles or in porous rock.

The added node then contains these default nodes: **Definitions**, **Geometry**, and **Mesh**. The settings for the **Extra Dimension** node are the same as for the **Component** node, except it has a unique **Name**.

The default nodes associated to the Extra Dimension are considered the extra dimension geometry and extra dimension mesh. The original geometry and mesh are called the base geometry and base mesh.

Before you can use the extra dimensions in physics interfaces, they must be attached on a selection in the base geometry.

The default node label in the **Label** field is **Extra Dimension 1** for the first **Extra Dimension** node. The component name is a string used to identify variables in the model. The default Extra Dimensions component name is `xdim1`, `xdim2`, and so on, but you can change it in the **Name** field.

	Using Extra Dimensions
---	------------------------

Branches and Subbranches in the Tree Structure

You can proceed through your modeling in the Model Builder by selecting the branches in the order suggested by the default positions, from the top down, or selecting and defining each branch as needed. One level below the main Component branch are subbranches as described in [Table 3-2](#) and shown in [Figure 3-2](#). The node appearance can also change depending on many factors. See [Dynamic Nodes in the Model Builder](#) for examples.

TABLE 3-2: THE MODEL BUILDER BRANCHES AND SUBBRANCHES

FIGURE REF.	ICON	NAME	DESCRIPTION AND LINK TO MORE INFORMATION
Main Branches			
1		Global Definitions	Define global parameters, and right-click to define global Variables, Functions, Load and Constraint Groups, a Materials branch, and optional Geometry Parts, Mesh Parts, and Extra Dimension branches, which are globally available in all model components. See The Global Definitions Node .
2	Various	Component	This branch includes the subbranches Definitions, Geometry, Materials, physics interfaces, and Mesh. You can also right-click the node to Add Physics and Add Mesh at this level. See The Component Node .
3		Study	This subbranch is where you set up study steps and solver configurations to solve a model using one or more study types for different analyses. See Studies and Solvers .
4		Results	The features contained in the subbranches for Data Sets, Derived Values, Tables, Export, and Reports are used to present and analyze results. See Results Analysis and Plots .
Subbranches			
5		Definitions (Local)	This subbranch is used to create Variables, Functions, Selections, Coordinate Systems, Component Couplings, and Probes as well as other definitions that are local to a specific component in your model. See Global and Local Definitions .
6		Geometry (Local)	This branch contains the definition of the model's geometry, where you can import a geometry or build one yourself using the available tools. See Geometry Modeling and CAD Tools .
7		Materials (Global)	This branch makes it possible to add materials and a material switch for material sweeps at the global level. You can add materials in the same way as you do under a Component branch, but materials on the global level are available throughout the model and therefore have no Geometric Entity Selection section. See Global Materials .
7a		Materials (Local)	Collect all material properties organized in Material nodes with a defined geometric scope. Material properties required by any of the physics interfaces and features show up automatically in the defined material's Settings window. See Materials .
8	Various	Physics interfaces	Each physics interface forms its own branch based on the model definition requirements. See The Physics Interfaces and Creating a New Model to start.

TABLE 3-2: THE MODEL BUILDER BRANCHES AND SUBBRANCHES

FIGURE REF.	ICON	NAME	DESCRIPTION AND LINK TO MORE INFORMATION
8a		Multiphysics	This is a main branch but is associated directly with the physics interface branches above it. It contains multiphysics coupling nodes. See The Multiphysics Branch .
9		Mesh	This subbranch collects all meshes defined for a model. If there is only a single mesh in a model, its Mesh node appears directly under the corresponding Component node. See Meshing .
10		Data Sets	Data Sets refer to the source of data for creating Plots and Reports. It can be a Solution, a Mesh, or some transformation or cut plane applied to other data sets; that is, you can create new data sets from other data sets.
		Derived Values	Used to define evaluations of numerical results — globally, in a point, or integrated quantities. For 2D and 3D plots, you can also get numerical results directly in a table by clicking the plot. See About Derived Values .
		Tables	This subbranch displays the results from integral and variable evaluations defined in Derived Values nodes or by probes and stored in Table nodes. See The Table Window and Tables Node .
Various		Plot Groups	After adding a 3D, 2D, or 1D Plot Group, plots are added and defined under this subbranch. See Plot Groups and Plots .
		Export	After a model is completed, you can add various components to this and then generate outputs (animations, data, images, or export), or export the information to your computer as image, movie, or data files for use in external documents or for other purposes. See Export Types .
		Reports	This subbranch opens the Report Generator, which is a tool for reporting and documenting models created in COMSOL. It creates a record of the entire model including all the settings made during the modeling process. The report is an overview of the model and includes model properties, geometry, physics interfaces and features, mesh, studies, and results and visualization. See Reports .

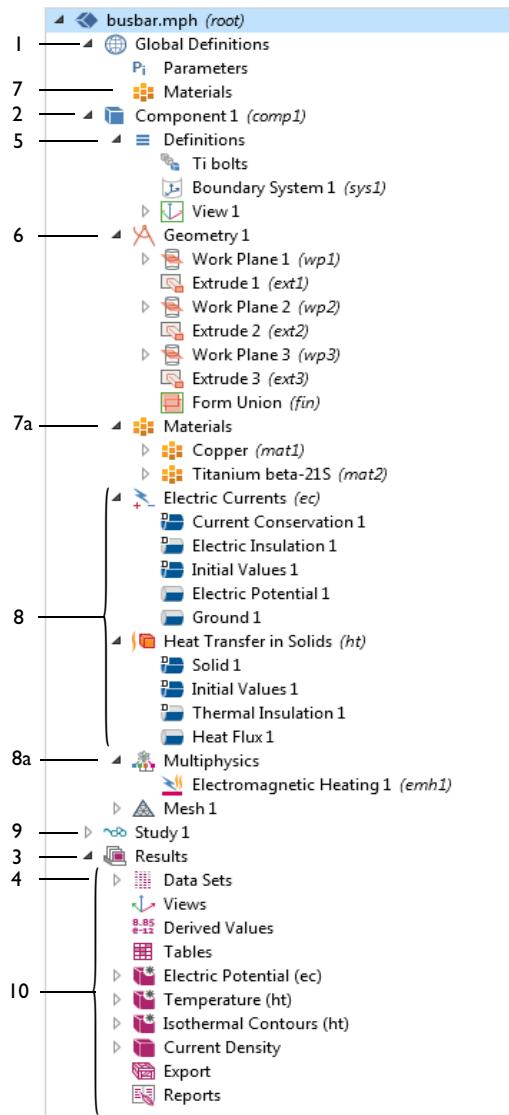

Figure 3-2: An example of the Model Builder tree structure showing the many different types of branches and subbranches available in a model. Refer to [Table 3-2](#) to learn more about a node. Use the numbers to locate the node in the table.

Settings and Properties Windows for Feature Nodes

SETTINGS WINDOW

For all operating systems, and when any node is clicked in the Model Builder (except a few *container nodes* such as **Definitions** and **Data Sets**), a corresponding **Settings** window opens with the same name as the node. The **Settings** window contains settings for defining operations and properties specific to a node, as shown in [Figure 3-3](#).

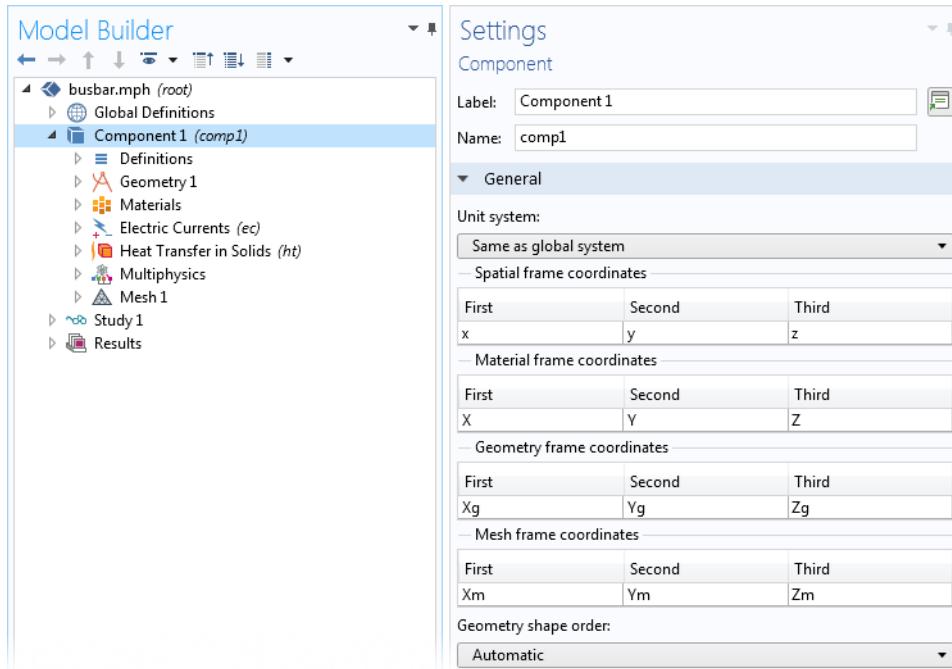

Figure 3-3: An example of a node Settings window. In this example, the Settings window for the Component node opens when the node of the same name is clicked. You can also toggle between the Settings and Properties window from the context menu.

SETTINGS WINDOW FUNCTIONALITY

When an operation or property is updated in the **Settings** window, its effect on the model is displayed in the Graphics window either instantaneously or by clicking the applicable button, which are available in some of the **Settings** window toolbars. If you update settings for the physics interfaces and features, you must recompute the solution to reflect the changes in the physics interface and features.

For most sequences, you can run the sequence by right-clicking the top node of the branch and selecting **Build All** (geometry) and **Build** (mesh), **Compute** (studies), or **Plot** (plot groups), or by pressing F8. These buttons are also on the **Settings** window and in the respective toolbars.

To select the parts of the model to define in a specific **Settings** window, select the relevant geometric entities directly in the displayed model in the Graphics window, from the Selection List window, or as, for example, **All domains** in the **Settings** window.

LABELS AND NAMES IN THE SETTINGS WINDOW

Every **Settings** window has the option to change the node **Label**. The **Label** is the default node description (it defaults to the node **Type** followed by an index suffix). For example, it might be the **Electric Currents** interface, or in [Figure 3-3](#) it is **Component**. You can also right-click and choose **Rename** or press F2.

Some **Settings** windows have the option to change the **Name**. These include physics interfaces, components (as in Figure 3-3), multiphysics couplings, and some Definitions features. The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the name string must be unique. Only letters, numbers, and underscores (`_`) are permitted in the **Name** field. The first character must begin with a lowercase or uppercase letter (a–z or A–Z). All other characters in the Name must be a lowercase or uppercase letter, a number between 0 and 9, or an underscore (`_`). See [Variable Naming Convention and Namespace](#) for more information.

You can choose to display any combination of the **Name**, **Tag**, and **Type** in the Model Builder. See [Displaying Node Names, Tags, and Types in the Model Builder](#).

In most **Settings** windows, there is also a **Create Shortcut** button () next to the **Label** field. Click it (or press Ctrl+K) to create a shortcut to that node for use in the Application Builder (see the Application Builder documentation for more information). If a shortcut already exists, you can click the **Rename Shortcut** button () (or press Ctrl+K) to rename the shortcut.

PROPERTIES WINDOW

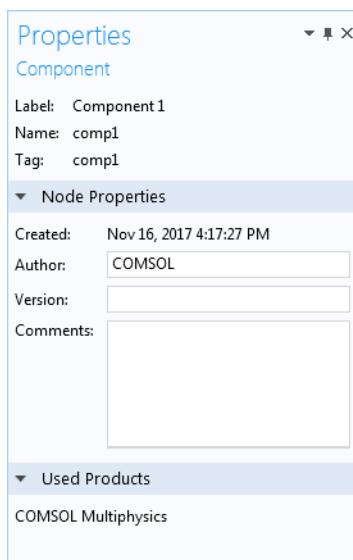

Figure 3-4: An example of a node Properties window. In this example, the Properties window for the Component node opens when you right-click the node and select Properties from the context menu. You can also toggle between the Settings and Properties window from this context menu.

The **Properties** window () in Figure 3-4 is accessed by right-clicking the node and choosing **Properties** from the context menu. The information listed includes the **Label**, **Name**, **Tag**, and the **Node Properties**.

- The **Label** can be edited on the Settings window. The default or edited name is displayed here but cannot be changed in this window.
- The **Name** is available for Component, functions and other nodes under Definitions, Material, and physics interface and multiphysics coupling nodes. You can edit the name on the Settings window for Component nodes, the main physics interface nodes, and for some functions and other nodes under Definitions, where the names serve as an identifier in the namespace for variables or as the function name, for example.
- The **Tag** is unique for each node and is assigned automatically. Tags are primarily used when running COMSOL models in Java or MATLAB. To display the Tag in the Model Builder, click **Model Builder Node Text** on the

toolbar and choose **Tag**. See [Displaying Node Names, Tags, and Types in the Model Builder](#) for more information.

- The **Node Properties** section includes the following information: **Created**, **Author**, **Version**, and **Comments** (the **Root** node is a special case; see [The Root Settings and Properties Windows](#)). The **Created** field is automatically assigned by the software. You can edit the **Author**, **Version**, and **Comments** fields in this window. For the **Comments** field, you can add formatting and special characters that will appear in reports. This information can also be included when creating Reports.

- Toolbars and Keyboard Shortcuts
- About Selecting Geometric Entities
- The Graphics Window

Displaying Node Names, Tags, and Types in the Model Builder

SELECTING THE MODEL BUILDER NODE CONTENTS

The Model Builder always shows the label for the nodes. To add more information, on the **Model Builder** toolbar click **Model Builder Node Text** . Then select any combination of options from the list: **Name**, **Tag**, and **Type**. See [Figure 3-5](#) for examples.

- A **Name** is only used in the Model Builder for short names (descriptions) of the nodes. The **Name** can only be changed for the top Component, physics interface nodes and multiphysics couplings, and for **Definitions** nodes. Some [Settings](#) windows have the option to change the **Name**. See [Settings and Properties Windows for Feature Nodes](#) for information about **Label** versus **Name**. The Name and Tag for top level features are often the same.

For **Definitions** features, the Name is displayed differently for Functions, Probes, Component Couplings, and Pairs. See [Common Settings for the Definitions Nodes](#) for more information.

- A **Tag** is unique for each node and is assigned automatically. Tags are primarily used when running COMSOL models in Java or MATLAB. Select **Tag** to display each node's feature name with the predefined tag in curly braces using an italic font. The Name and Tag can be the same.
- A **Type** is automatically assigned by the software and cannot be changed. Select **Type** to display each node's feature type (predefined name). This is the most useful if a node **Label** is renamed or if you use a local language other than English and want to see the predefined name; otherwise, the type and the label are the same (except that the label typically includes a number, such as *Boundary System 1*).

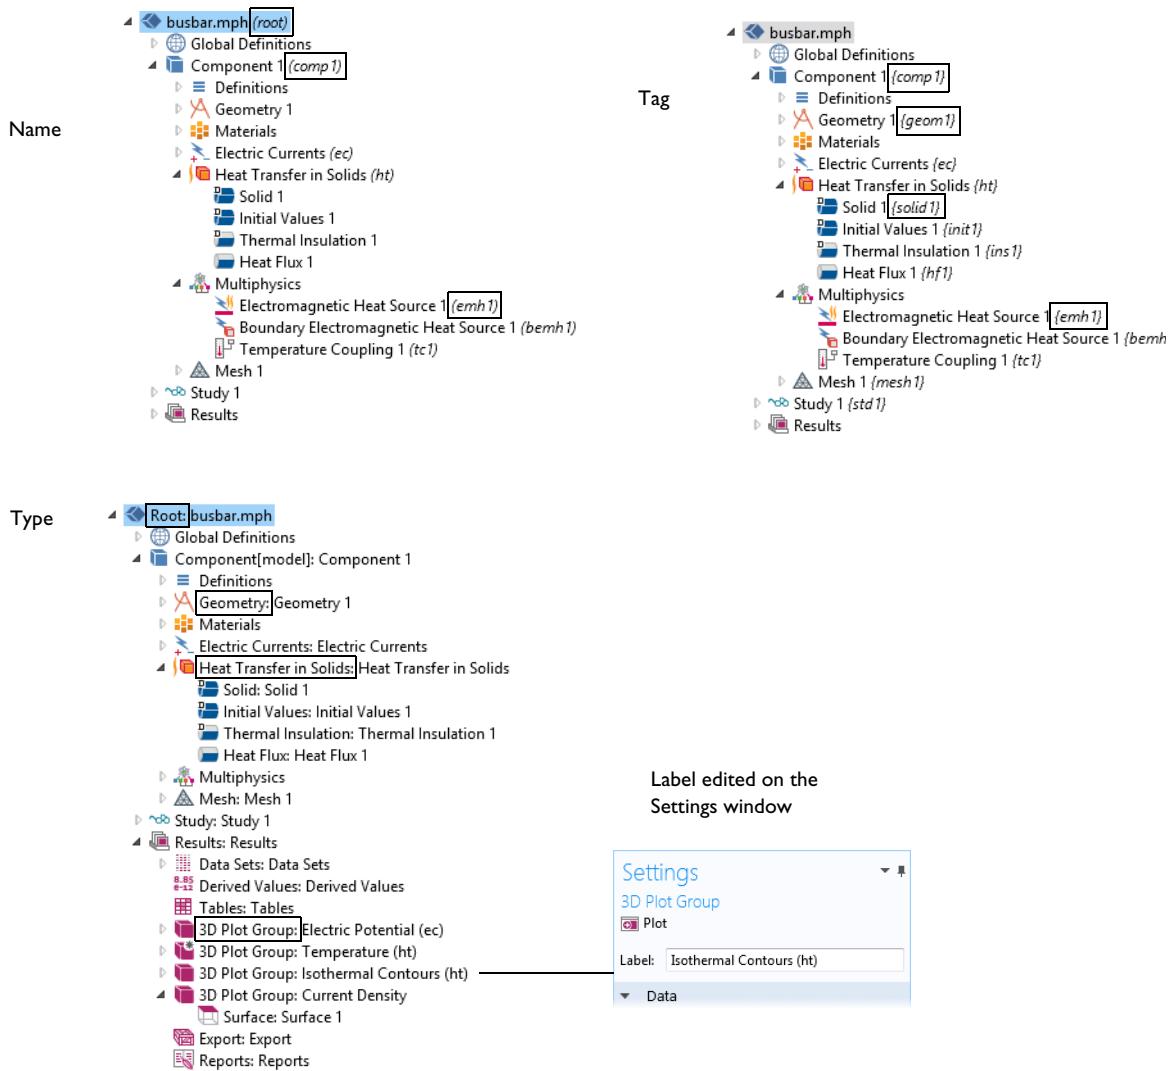

Figure 3-5: Examples of the available combinations on the Model Builder Node Label menu. The second example of a Type shows how this is useful when the Label is edited in the Settings window and you need to know the original type of node.

LABELS

Node **Settings** windows have a **Label** field where you can change the default node description for all levels (except the Root node, which gets its name from the model filename). The label can also be changed by right-clicking and choosing **Rename** or by pressing F2.

	The Label can also be displayed in the Model Builder where it is called a Tag . See Settings and Properties Windows for Feature Nodes .

Opening Context Menus and Adding Nodes

In addition to using the toolbars and menus (see [The COMSOL Desktop Menus and Toolbars](#)), you can right-click a node to open a *context menu*. The context menu lists all the functionality available as properties and subnodes to a particular node in a branch of the tree. [Figure 3-6](#) shows the context menu for some of the Geometry node options. From the menu you can add additional, and relevant, functionality, operations, or attributes to the sequence. Often there is a mixture of submenus, keyboard shortcuts, or specific features to choose from as in [Figure 3-6](#) and [Figure 3-7](#). There are also standard options such as **Rename**, **Properties**, and **Help**.

The context menu is also further divided and categorized for physics interfaces, as in the section [Physics Interface Node Context Menu Layout](#) and [Figure 3-7](#).

To add physics feature nodes to physics interfaces, in general, go to the **Physics** toolbar, no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the galleries that open.

The layout of the context menu (especially for physics interfaces) depends on whether the nodes are grouped by space dimension. The default is ungrouped nodes. See [Grouping Nodes by Space Dimension and Type](#) for an example comparing the different context menus.

OPENING THE CONTEXT MENU

- Right-click any node in the **Model Builder** to open the context menu
- Once a node is highlighted, right-click anywhere in the **Model Builder** to open it.
- Use the shortcuts based on operating system:
 - Windows: Press Shift+F10.
 - macOS: Press Ctrl+F10.
 - Linux: Press Shift+F10.

After selecting an option from the list, an associated **Settings** window opens to the right (by default) of the **Model Builder** window. See [Figure 3-3](#) for an example.

In the context menu, a plus sign next to any icon () means a node of that type is added to the **Model Builder**.

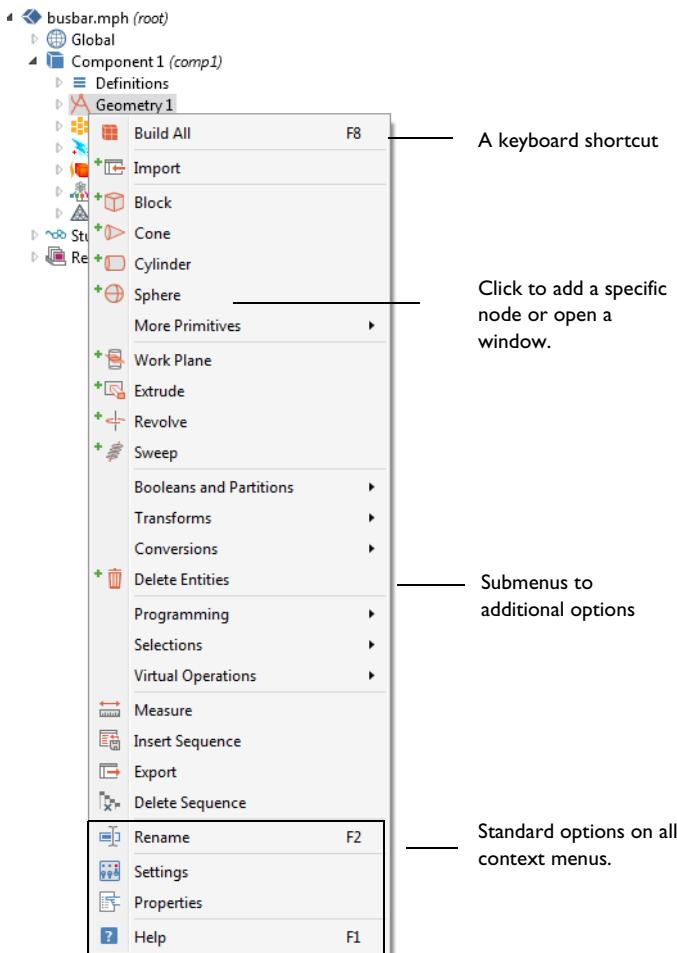

Figure 3-6: A context menu opens when you right-click any node in the Model Builder. In this example, the options available for the Geometry node are shown.

- Settings and Properties Windows for Feature Nodes

- About Geometric Entities

The Physics Nodes

An important part of building a model is where you add physics branches. For example, when [Creating a New Model](#). This branch (see [Figure 3-2](#) for an example) contains the nodes that define the material properties, equations, loads, initial values, boundary conditions, and other parts of the physics that the model describes. All **Settings** windows for the specification of the physics and equations accept parameters and variables as input data.

SPECIFYING PHYSICS INTERFACE SETTINGS

Each physics interface includes nodes for specifying all input data for a specific physics in a model:

- Material properties and material models

- Boundary and physics interface conditions
- Equations (for equation-based modeling)
- Initial conditions

In addition, you can specify weak form contributions and element types for additional flexibility.

Specifically, the settings are available on the following parts of the geometry:

- Domains
- Boundaries
- Edges
- Points
- Additional properties that are independent of the geometry

Not all of these options are available for all geometry types and physics interfaces.

PHYSICS FEATURE NODES BY SPACE DIMENSION

The physics feature nodes indicate the geometric entity level (domains, boundaries, edges, points, or pairs) based on the space dimension of the Component (see [Table 3-3](#)). The nodes also correspond to [The Graphics Window Toolbar Buttons and Navigation](#), some of which are also based on space dimension.

See [Physics Exclusive and Contributing Node Types](#) and [Physics Node Status](#) for examples of other differences to how the nodes display in the Model Builder.

TABLE 3-3: PHYSICS FEATURE NODES BY SPACE DIMENSION

NAME	3D	2D AND 2D AXISYMMETRIC	ID AND ID AXISYMMETRIC

 - [Physics Interface Default Nodes](#)
 - [Physics Interface Node Context Menu Layout](#)
 - [Physics Node Status](#)
-

Physics Interface Default Nodes

When you add a physics interface, the software automatically adds a corresponding physics interface branch in the tree, which typically includes a number of default nodes, including but not limited to:

- A model equation or material model node, typically on the domain level. This node defines the domain equations (except optional sources, loads, reactions, and similar contributing domain quantities) and the related material properties or coefficients.
- A boundary condition node. For multiphysics interfaces there is one boundary condition for each participating physics.
- For axisymmetric models, the symmetry axis has an **Axial Symmetry** boundary condition (see [Physics Interface Axial Symmetry Node](#)).
- An **Initial Values** node for specifying initial values for a time-dependent simulation or an initial guess for the solution to a nonlinear model (see [Specifying Initial Values](#)).

In most cases, the default nodes' initial selections include all domains or all boundaries (or all instances of another geometric entity level). Their selection is always every instance that is not overridden by another node on the same geometric entity level. It is not possible to delete such default nodes, but you can copy and duplicate all default nodes. Some multiphysics interfaces also add default nodes with no initial selection, which are possible to delete from the model. Default nodes include a *D* (for “default”) in the upper-left corner () to indicate their special status. The copy or duplicate of a default node is a node of the same type but behaves as a normal node with an initially empty selection.

For example, for a geometry with four boundaries, the default boundary condition's initial selection includes all four boundaries. If another exclusive boundary condition for Boundary 3 is added, that boundary becomes overridden (inactive) in the default boundary condition's selection. If you disable or remove that boundary condition, the default boundary condition becomes active for Boundary 3 again. You cannot change a default node's selection.

Some physics interfaces also add standard nodes directly when you add them to a model. They represent functionality that is likely to be useful but that you might want to make only active on a part of the geometry or delete. Such nodes do not include a *D* in the upper-left corner.

-

Physics Interface Node Context Menu Layout

The context menu opens when you right-click a physics interface node, or any node in the Model Builder (see [Opening Context Menus and Adding Nodes](#)). Depending on the space dimension, this menu is divided into these

sections for most physics interfaces: the first section contains domain settings, the second boundary settings, the third edge settings, and the fourth has point settings.

There can be menu items with the same name but applied at different geometric entity levels.

To add physics feature nodes to physics interfaces, in general, go to the **Physics** toolbar, no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the gallery that opens.

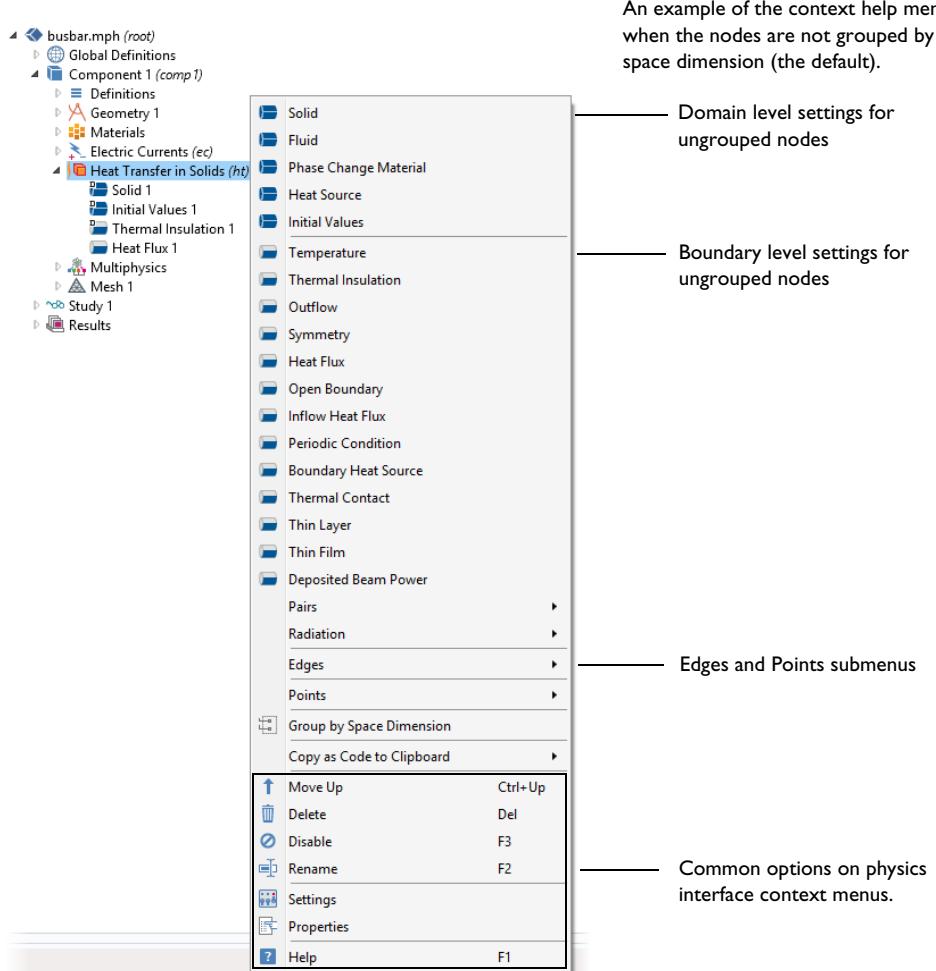

Figure 3-7: An example of a Heat Transfer in Solids interface context menu. The choices are based on the Component dimension (in this example it is 3D) as well as the physics interface. The menu is further divided by geometric entity level (domains, boundaries, edges, and points).

As shown in [Figure 3-7](#), the context menu layout is also based on whether the nodes are not grouped (the default) or if **Group by Space Dimension** is selected.

Physics Exclusive and Contributing Node Types

The nodes for the physics interfaces and features are in a sequence, which acts like a macro that the software runs in a top-down order. Depending on the selection for each node, a node can totally or partially override, or shadow, a node earlier in the sequence. How the software treats these nodes depends on the relationship. There are two different types of nodes: *exclusive* and *contributing* (see [Figure 3-8](#))..

The exclusive and contributing nodes maintain the described behavior only in relation to similar types of nodes within the same physics interface (for example, you can have a temperature constraint and a pressure constraint for the same boundary in the same model component).

What the node looks like in the Model Builder is based on the space dimension. See [Physics Feature Nodes by Space Dimension](#).

EXCLUSIVE NODES

The use of an *exclusive node* means that only one can be active for a given selection. That is, if you add another exclusive node (for example, an identical node) with the same selection, the first exclusive node is overridden and thus has no effect.

Typical exclusive nodes include model equations, initial values, and boundary conditions that are constraints, such as prescribed values for displacements, temperatures, pressures, and so on, including special variants of these such as ground conditions in electromagnetics and fixed constraints in structural mechanics. Also some boundary conditions that are not constraints but have a definitive meaning are exclusive nodes — for example, electric insulation, thermal insulation, and no-flow conditions. Depending on the selections for each node, an exclusive node can override another node partially. Nodes are exclusive only within their specific physics interface. When a node is selected in the Model Builder tree, nodes that are overridden by the selected node have a red arrow in the lower-left corner of the icon (), and nodes that override the selected node display a red arrow in the upper-left corner of the icon ().

CONTRIBUTING NODES

A *contributing node* means you can have more than one of these nodes with the same selection and that the software adds these together when evaluating the model. Typical contributing nodes are loads, fluxes, and source terms, where you can have more than one of each type that is active on the same domain or boundary, for example. The total effect is then a sum of each contributing node. When a node is selected in the Model Builder tree, the tree shows other nodes, which the current node contributes with, indicated using a yellow dot to the left of the icon (for example, in this boundary level icon). See also [Figure](#) for an example.

LISTING OVERRIDES AND CONTRIBUTIONS

If your preferences include showing the **Override and Contribution** section in the **Settings** windows for physics nodes, you can find the following information about how exclusive and contributing nodes interact in the model. Click the **Show** button () and select **Override and Contribution** from the **Model Builder** to display the information as in [Figure 3-8](#) and described below.

- The **Overridden by** list contains the names of the nodes that the selected node is overridden by. The selected node is then overridden by these nodes at least partially, and the **Selection** list contains **(overridden)** for the geometric entities (boundaries, for example) where it is overridden. The nodes that the selected node is overridden by are indicated using a red arrow in the lower-left corner of the icon such as in this boundary level icon .

- The **Overrides** list contains the names of the nodes that the selected node overrides (where the current node is active). The nodes that the selected node overrides are indicated using a red arrow in the upper-left corner of the icon such as in this boundary level icon .
- The **Contributes with** list contains the names of the nodes that the selected node contributes with for at least some shared selection. The nodes that the selected node contributes with are indicated using a yellow dot to the left of the icon such as in this boundary level icon .

If a physics node is disabled locally in a study step using the **Physics and Variables Selection** section in the study step's **Settings** window, the indications of overrides and contributions in the Model Builder are unchanged (but disabled physics nodes get an asterisk to indicate that their state has been changed in at least one study step). The local variables and physics tree in the study step's **Settings** window, on the other hand, display the overrides and contributions taking the disabled nodes into account.

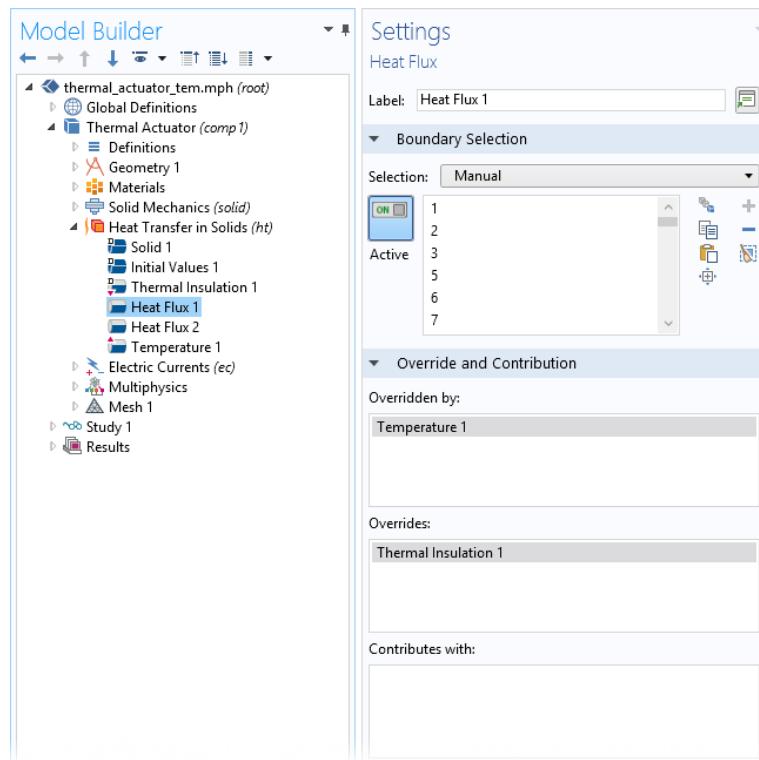

Figure 3-8: The Override and Contribution section lists other physics nodes that the selected node is overridden by, overrides, or contributes with.

- Physics Node Status
- Physics and Variables Selection
- Physics Interface Default Nodes

Physics Node Status

The status of a physics node depends on if it is a default node, the selection that it applies to, and other nodes in the same branch that can override nodes earlier in the sequence. You can change the order of nodes (except the default nodes) by moving them up or down.

OVERIDDEN SELECTIONS

A node can be partially or completely *overridden* by another node further down in the same branch of the model tree that is of a similar, exclusive type. For example, if you specify a temperature boundary condition on boundary 1 and boundary 3, and then add another temperature boundary condition for boundary 3, the first temperature boundary condition is overridden on boundary 3. In the **Settings** window for the **Temperature** nodes that define the temperature boundary condition, the **Selection** list then shows **3 (overridden)** to indicate that the temperature boundary condition defined on this selection is overridden for boundary 3 but is still active on boundary 1. Deleting or disabling the other temperature boundary condition on boundary 3 reactivates the original temperature boundary condition, and then shows **3** (without the **(overridden)** indication).

SELECTIONS THAT ARE NOT APPLICABLE

For selections that are not applicable for a node (such as interior boundaries for an boundary condition that is only applicable for exterior boundaries), the **Selection** list then shows **(not applicable)** next to entries that are, in this case, interior boundaries.

EMPTY SELECTIONS

For physics nodes that you add to a model, a warning appears on the physics node when the node has no selection. An added source or boundary condition, for example, has no effect on the model, so leaving an added physics node with an empty selection might be an unintended state, leading to unexpected simulation results.

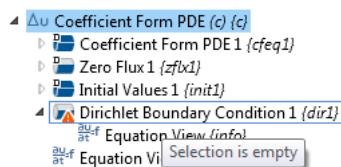

Figure 3-9: The warning and tooltip for an added physics node with an empty selection.

The warning for an empty selection does not appear in the following cases:

- For completely overridden selections.
- When no applicable entities are available.
- When selections are set to all entities, but the geometry has no entities on the given entity level (for example, no geometry or domain selection on a surface geometry).

ENABLING AND DISABLING NODES

By enabling or disabling physics nodes, you can activate and deactivate (shadow) other physics interface nodes that appear higher up in the physics interface branches.

Dynamic Nodes in the Model Builder

The **Model Builder** is a dynamic environment. As your model is built and analyzed, there are numerous ways to quickly identify nodes that change status during the process. [Table 3-4](#) lists generic examples and links to the dynamic visual aids that are used to help you.

	<ul style="list-style-type: none"> • Branches and Subbranches in the Tree Structure • The Component Node

ICON	TYPE	NODE EXAMPLE AND LINK TO MORE INFORMATION (WHERE APPLICABLE)
	Disable in Solvers	For example, a Laminar Flow interface is enabled (not dimmed), shows that the study step provides degrees of freedom (the yellow dot in the lower-right corner), and has a change of state indicated by the asterisk. The yellow dot means that the study step provides degrees of freedom but does not solve for the physics interface. See Physics and Variables Selection .
	Change of State (editing)	An asterisk appears in the upper-right corner of nodes for which you change their state in the study step's selection tree compared to their state in the main model tree in the Model Builder. For example, for the Joule Heating interface .
	Disabled in Model (provides no degrees of freedom) and shows a change of state	In this example, a Transport in Diluted Species interface is disabled (unavailable), provides no degrees of freedom (red dot in the lower-right corner), and has a change of state indicated by the asterisk. See Physics and Variables Selection .
LOAD AND CONSTRAINT GROUPS		
	Load Group	This is an example of a Boundary Load node with a load group . This is for a 2D model at the boundary level. See Load Group and Using Load Cases .
	Constraint Group	This is an example of a Fixed Constraint node with a constraint group . This is for a 2D model at the boundary level. See Constraint Group and Using Load Cases .

Physics Symbols

There are physics symbols available with structural mechanics and some other physics features to help you to graphically indicate boundary conditions, loads, and other physics features:

- [Physics Symbols for Structural Mechanics and Other Physics](#)
- [About Coordinate Systems and Physics Symbols](#)
- [Displaying Physics Symbols in the Graphics Window — An Example](#)

- [Solid Mechanics and Using Load Cases](#)
- [The Graphics Window](#)

PHYSICS SYMBOLS FOR STRUCTURAL MECHANICS AND OTHER PHYSICS

To display the physics symbols listed in [Table 3-5](#), select the **Enable physics symbols** check box under **Physics Symbols** in the main physics interface node's **Settings** window. This check box is not selected by default.

Once you have turned on the physics symbols for a certain physics interface, you can fine-tune the display. Every feature that has associated physics symbols now has a **Show physics symbols** check box, by which you can control the display of the symbols for that specific feature.

In the **Physics Symbols** section in the settings for the physics interface, you can click the **Select All** button, which displays all symbols in that physics interface by selecting all **Show physics symbols** check boxes in the **Settings** windows for the physics features that include symbols. Similarly, the **Clear All** button clears all **Show physics symbols** check boxes in the individual physics features.

The following symbols are available with the applicable structural mechanics feature nodes and with some other physics interfaces (this table is a partial list of available symbols).

TABLE 3-5: PHYSICS SYMBOLS

SYMBOL	SYMBOL NAME	DISPLAYED BY NODE	NOTES
	Added Mass ¹	Added Mass	
	Antisymmetry ¹	Antisymmetry	
	Body Load ¹	Body Load	
	3D Coordinate System		Green indicates the Y direction, blue indicates the Z direction, and red indicates the X direction.
	2D Coordinate System		Green indicates the Y direction and red indicates the X direction.
	Distributed Force	Boundary Load Face Load Edge Load	Can be displayed together with the Distributed Moment symbol, depending on the values given in the node.
	Damping ¹	Spring Foundation	Can be displayed together with the Spring symbol, depending on the values given in the node.
	Distributed Moment ¹	Boundary Load Face Load Edge Load	Can be displayed together with the Distributed Force symbol, depending on the values given in the node.
	Fixed Constraint	Fixed Constraint	
	No Rotation ¹	No Rotation	
	Pinned ¹	Pinned

ABOUT COORDINATE SYSTEMS AND PHYSICS SYMBOLS

Physics symbols connected to a node for which input can be given in different coordinate systems are shown together with a coordinate system symbol. This symbol is either a triad or a single arrow. The triad is shown if data are to be entered using vector components, as for a force. The single arrow is displayed when a scalar value, having an implied direction, is given. An example of the latter case is a pressure.

In both cases, the coordinate directions describe the direction in which a positive value acts. The coordinate direction symbols do not change with the values actually entered for the data.

Physics symbols are in most cases displayed even if no data values have been entered in the node.

In some cases, a single feature can display more than one symbol. An example is the Point Load node in the Beam interface, which can display either the Point Force symbol (), the Point Moment symbol (), or both, depending on the data entered. In those cases, no symbol is shown until nonzero data is entered.

For cases when physics symbol display is dependent on values given in the node, it can be necessary to move to another node before the display is updated on the screen.

DISPLAYING PHYSICS SYMBOLS IN THE GRAPHICS WINDOW — AN EXAMPLE

- 1 Add a physics interface, for example, **Solid Mechanics**, from the **Structural Mechanics** branch.
- 2 In the Solid Mechanics node's Settings window, under **Physics Symbols**, select the **Enable physics symbols** check box and then click the **Select All** button.
- 3 Add any of the feature nodes listed in [Table 3-5](#) to the physics interface. Availability is based on license and physics interface.

The physics symbols also display for any multiphysics interface that includes Structural Mechanics feature nodes or other physics feature nodes with symbols.

- 4 When adding the boundary, edge, or point (a geometric entity) to the **Selection** list in the feature **Settings** window, the symbol displays in the **Graphics** window. See [Figure 3-10](#) and [Figure 3-11](#).

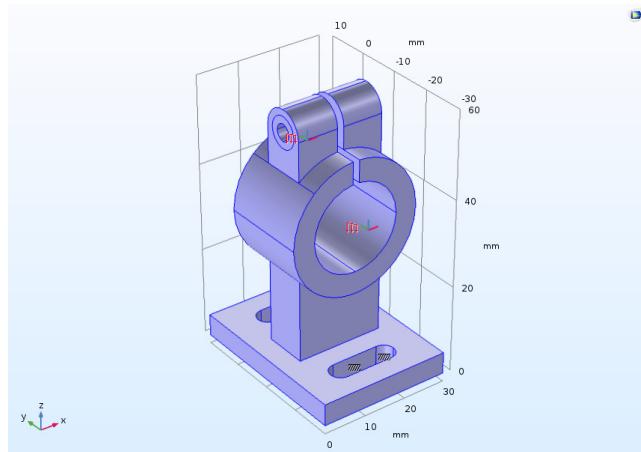

Figure 3-10: Example of Boundary Load physics symbols as displayed in the COMSOL Multiphysics model “Deformation of a Feeder Clamp”.

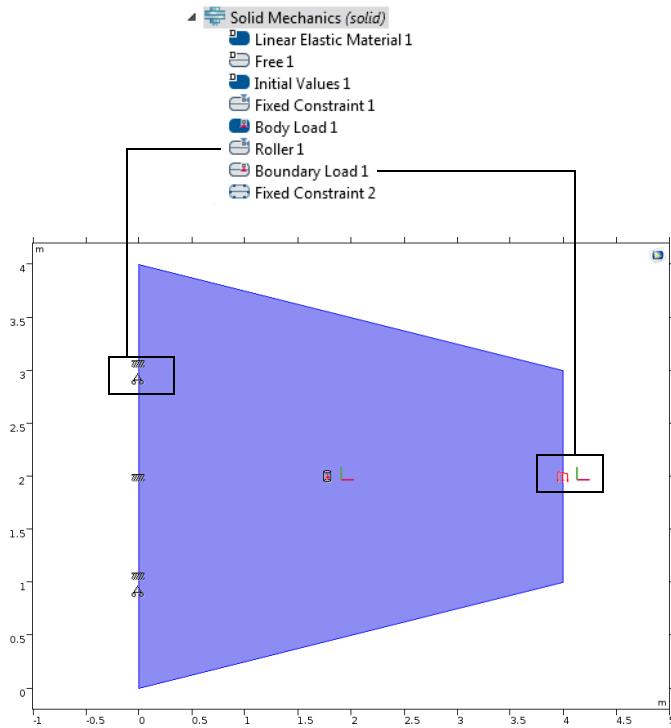

Figure 3-11: Example of Roller and Boundary Load physics symbols as displayed in the COMSOL Multiphysics model “Tapered Cantilever”.

Errors and Warnings

COMSOL Multiphysics reports problems of two types: errors and warnings.

ERRORS

Errors prevent the program from completing a task. For errors, a **COMSOL Error** window appears with a brief error description and, in some cases, an **Open Log File** button for additional information. Under the node where the error occurred there is, in most cases, also an **Error** subnode (✖) that contains an error message that generally provides

additional information. Also, for many error types, the icon for the node where the error occurred appears with a red cross in the lower-right corner. For some errors there is also a link to more diagnostic information on the COMSOL website.

LICENSE ERRORS

It is possible to open and postprocess models that include functionality that you have blocked or that your license does not include. Nodes with functionality that requires a license for a product that is blocked or not available get a **License Error** subnode (✖), where you find information about the missing but required product license. Unless you disable or remove such nodes, it is not possible to re-solve such models.

Some specialized plot types require a license for an add-on product and are then also unavailable if you postprocess models that include such plots and your license does not include the required product.

It is not possible to open models that require a license for the Material Library, ECAD Import Module, CAD Import Module, LiveLink™ for MATLAB®, or any of the CAD LiveLink™ products if your license does not include this required product.

WARNINGS

Warnings are problems that do not prevent the completion of a task but that might affect the accuracy or other aspects of the model. Warnings typically appear in the **Log** window (Logs). The warning message also appears as a **Warning** subnode (⚠) under the node from which the warning was sent.

INDICATION OF UNEXPECTED, UNKNOWN, OR INCONSISTENT UNITS

The unit display appears orange for the properties in the settings for the physics interface, physics features, and materials that have invalid or inconsistent units or a different unit than expected. An inconsistent unit can occur by summing terms with units that represent different physical quantities, such as $273[K]+3[ft]$. A tooltip displays a message at the corresponding field. In the case of a valid but unexpected unit, this message contains the deduced and expected units in the current unit system.

If an unexpected or inconsistent unit appears in a text field for a physical property, the COMSOL Multiphysics software ignores the unit and uses the numerical value, including an SI prefix if present, as the input to the model. For example, in a text field for density using SI units, the software interprets $2930[K]$ as 2930 kg/m^3 and $2930[mK]$ as 2.930 kg/m^3 . A unit display that appears red contains a syntax error, which can be due to, for example, missing or misplaced parentheses.

ERRORS AND WARNINGS IN A GEOMETRY SEQUENCE

If an error occurs when you build a node, the build stops. The node with the problem then gets an **Error** subnode (✖) that contains the error message. Also, the node's icon displays with a red cross in the lower-left corner.

After a successful build of a node, a warning message can sometimes display as a **Warning** subnode (⚠). If a warning message exists, the node's icon displays with a yellow triangle in the lower-left corner.

ERRORS AND WARNINGS IN MESHING SEQUENCES

If a problem occurs when you build a node, the build continues if it is possible; otherwise, the build stops. Continuing means that geometric entities where the operation failed are skipped and the problems are reported as **Error** subnodes (✖) under the operation node. The build process continues with remaining nodes in the meshing sequence.

When the building of the meshing sequence is completed, the error window appears to show the first error reported. If there are several errors, you have to inspect the sequence for nodes with a Warning status and corresponding **Error** nodes to find all errors. If a node has a Warning status, the node's icon includes a yellow triangle in the lower-right corner (see [Dynamic Nodes in the Model Builder](#)).

In some cases, you get a **Warning** node () even though meshing completed successfully. This happens, for example, when geometric entities are much smaller than the desired mesh element size, and you should interpret the warning as a hint that the geometry needs to be simplified to avoid an unnecessarily fine mesh.

The **Error** and **Warning** nodes and their subnodes often contain selections that highlight where the problem is located in the geometry.

If meshing cannot continue, all building stops and the node gets an Error status, which the program indicates by adding a red cross in the lower-right corner of the node's icon. You find information about the error in an **Error** subnode () of the node where the error occurred. If the node is part of a sequence build, the build stops and the preceding node becomes the current node.

ERRORS AND WARNINGS IN SOLVER SEQUENCES

Issues encountered when running a solver or generating a mesh are treated in two different ways depending on if it is possible to avoid the problem and continue the operation or if the operation must be stopped. In the first case, a **Warnings** node () appears under the node in the model tree that caused the problem. In the second case, an **Error** node () appears under the node in the model tree that caused the error.

WARNINGS DURING POSTPROCESSING

For things like empty plots, **Warnings** nodes () can appear in the **Results** branch during postprocessing. However, you do not get any warnings in these cases:

- Plotting with the **Data set** list set to **None** or a data set that cannot be evaluated (for example, because the model does not contain any solution).
- Plotting without having set any expressions.

If you still have problems, contact technical support from the Support Center page at www.comsol.com/support.

- [Unit Systems](#)
- [Dynamic Nodes in the Model Builder](#)

Creating and Running Methods in Models

You can use the method editor capabilities in the Application Builder to create methods that you can run to automate or extend operations in the **Model Builder** tree such as creating a geometry or running some special solver sequence. To add a method, go to the **Developer** ribbon and click **New Method** () in the **Create Methods** section. In the **New Method** window, specify a method name in the **Name** field and click **OK**. The Application Builder then opens, and the new model method appears under **Methods** () in the **Application Builder** tree. You can then record or write code for the method in the model editor window. See the Application Builder documentation for more information about methods. By default, the **Show in Model Builder** check box is selected in the settings for the **Method** node. All methods with that check box selected appear under **Run Method** in the **Model Builder**.

To run a method in the Model Builder, click **Run Method** () in the **Run Methods** section and choose the method to run. The Model Builder tree is updated according to the changes that the method includes. Click **Stop** () to stop a running method to debug it, for example. You can open the **Debug Log** window from the **Windows** menu to view debug information. You can also add breakpoints for debugging purposes. You can also click **Run Method Call** () to run a method call in a **Method Call** node (see [Method Calls](#) below). Method calls support input arguments for the model methods, so that you, for example, can use two instances of the same model method with different input values. Model methods with inputs are not available for **Run Method**. For methods without inputs, running a method directly or through a method call is equivalent.

Make sure that the model tree is in a state that is compatible with the method that you run. Otherwise, the method code may not work or may produce unexpected results. Also, there is no undo operation after running a model method.

See the *Introduction to Application Builder* for an example of a model method and the *Application Builder Reference Manual* for information about the **Model Method** node and about creating and debugging methods in general.

Method Calls

You can add any available model method as a **Method Call** node (), which appears under **Global Definitions**. If the Group by Type option is enabled, the **Method Call** nodes are grouped under the **Method Calls** node (). In the **Settings** window, the model method that this **Method Call** node calls is listed as, for example, **Model method: modelmethod1**.

At the top of the **Settings** window, click the **Run** button () or press F8 to run the model method for this method call. Click the **Stop** button () to stop a running model method (this button is unavailable if a model method is not running).

Click the **Edit Method** button () to open the model method in a method editor window in the Application Builder, where you can make changes and additions to the model method.

You can also right-click the **Method Call** node and choose **Run** () (or press F8) or **Edit Method** ().

The **Method Call** node's **Settings** window includes the following section:

INPUTS

In this section, any inputs that you have defined for the model method appear, using the input's description as the label and a text field for entering a value for the input (the text field contains a default value if it has been defined for that input). If the input is a Boolean, it appears as a check box instead. If the input is a 2D array, Array 1D Boolean, or Array 1D String, it is shown as a table, where you can add values and add rows and columns as applicable. Contrary to running model methods directly, method calls can use model methods with inputs defined in the **Settings** window for model methods in the Application Builder. That way you can, for example, use multiple instances of a model method with different input values.

Creating and Using Settings Forms and Dialogs

Forms that you create in the Application Builder can also be used as settings forms in the **Model Builder** tree that can provide customs settings connected to methods for performing some special task in a model. Such forms become available in the **Model Builder** if you select the **Show in Model Builder** check box. You can add them as nodes in the **Forms** section of the **Developer** toolbar by choosing them from the **Settings Form** list (). That form is then

added as a **Settings Form** node under **Global Definitions** (or **Global Definitions>Settings Forms**, if **Group by Type** is active).

You can also show such forms as modal dialog boxes by choosing them from the **Show Dialog** list (in the **Forms** section of the **Developer** toolbar.

Forms that include Graphics objects cannot be used as settings form or dialog boxes. Instead you can plot in the main **Graphics** window or in other plots windows using the built-in `selectNode` method or the `window` property for a plot group.

To make use of the latest definition of a form in the Application Builder when it is shown in the Model Builder, click the **Update Forms** button () in the **Forms** section of the **Developer** toolbar, which updates all settings forms' features. You can also click the **Update** button () in the **Settings** window for a **Settings Form** node to update that particular settings form.

Click the **Edit Form** button () the in the **Settings** window for a **Settings Form** node to move to its form editor window in the Application Builder.

See the Application Builder documentation for more information about creating forms and methods.

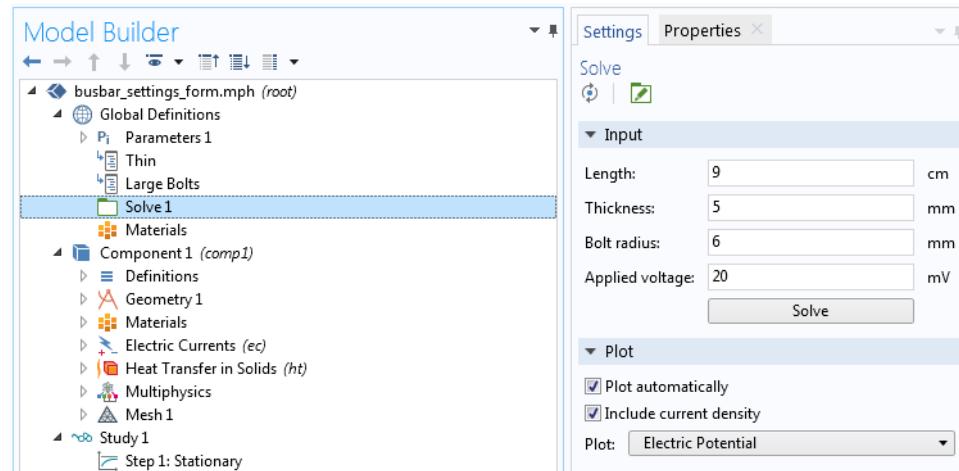

Figure 3-12: An added settings form under Global Definitions provides custom settings.

Comparing Models and Applications

It can be useful to compare two versions of the same model or application to get an overview of the differences between the two versions. To do so, click the **Compare** button () in the **Compare** section of the **Developer** toolbar. A **Select Application** window then opens, where you can select the Model MPH-file (the remote file) to which you want to compare the current model in the COMSOL Desktop (the local file). A comparison then starts, and the results, if there are any differences, appear as a tree in the **Comparison Result** window. The comparison tool compares all the settings in the entire model, including visible and invisible settings in the Model Builder and the Application Builder.

THE COMPARISON RESULT WINDOW

At the top of the **Comparison Result** window there is a toolbar with the following buttons:

- **Update** (), to update the comparison
- **Collapse All** () and **Expand All** (, to collapse or expand all branches in the comparison tree
- **Load Comparison from File** (, to load the results from another comparison from an XML-file.
- **Save Comparison to File** (, to save the results from the current comparison to an XML-file.

Under **Comparing files**, you find the file paths to the local model and the remote model. The local model is typically the model open in the COMSOL Desktop, and it can have been modified after the last save. The left column is called **Local file (Open application)** when the local model is the opened model or application. When the local model is a new model that has not yet been saved, the left column is called **Open application**.

Under **Differences**, you can use the **Filter results** list to control filtering with the options **No filter**, **Exclude all matching labels** (the default), and **Include all matching labels**. The entries in the **Regular expression** field define what node labels to filter; that filtering which also can be made case sensitive by selecting the **Case sensitive** check box next to the list. The filter matching is done with regular expressions, and any label that contains a matching text will be either included or excluded. Filtering can be disabled by choosing **No filter** from the **Filter results** list.

The tree itself has a structure according the structure of the underlying model object, not the Model Builder or Application Builder trees. This means that the hierarchy can be somewhat different compared to the hierarchy seen in the **Model Builder** and **Application Builder** windows. The comparison includes all nonbinary differences in the model object that can be saved to disk, with some exceptions. Below is a list of consequences of this design:

- The tree can show differences not visible in the Model Builder because they come from inactive settings hidden by another setting.
- Some settings and nodes in the Model Builder are not saved in the model object and will therefore not show in a comparison (Mesh Statistics, for example).
- No binary data are compared, so, for example, no differences in the solution will trigger a difference in the comparison.

Selecting a node in the tree will update the table under **Comparing values** below the tree. This table shows the attributes of the selected node, both in the local model (**Local value** column) and the remote model (**Remote value** column). This table is particularly interesting for the nodes labeled **Attributes differ** because they show the values that differ. Parent nodes can also show the same differences but typically with a larger number of attributes that have the same local and remote values. For differences that contain long entries or large arrays, there is an option to show a more detailed difference in a separate window for a selected table. Either double-click the table row or click the **Detailed Comparison of Selected Attribute** button () below the table to open the **Compare Attribute** window.

Working with Nodes in the Model Builder

Moving Nodes in the Model Builder

Many of the nodes under the branches and subbranches listed in [Table 3-2](#) can be moved around in the model tree.

To move nodes use one of these methods:

- Select one node at a time (or by Ctrl-clicking or Shift-clicking to select more than one node at a time), and use the mouse to drop them in another applicable position in the model tree. A horizontal line indicates where in the model tree the moved (or copied) nodes get inserted when releasing the mouse.
- Right-click the selected nodes and select **Move Up** (↑) or **Move Down** (↓). Nodes that are the first or last of its kind can only be moved down or up, respectively.
- Use the keyboard shortcuts Ctrl+up arrow or Ctrl+down arrow to move nodes up or down.
- You can also create custom grouping of nodes to organize the nodes in the model tree. See [Custom Grouping of Nodes](#).

For physics interface nodes it is not possible to move the default nodes (for the default boundary condition, for example). It is possible to create a copy of a default node, which initially has no selection. To click-and-drag a default node creates a copy whether or not the Ctrl key is pressed.

The order of the nodes in some of the branches affects the evaluation of the sequence that they define. In the following branches and subbranches it is possible to move nodes up and down to control the evaluation of the sequence or the order in which they appear within the branch or subbranch (also see [Table 3-2](#)):

- **Definitions:** nodes can be moved relative to other nodes of the same type (functions, selections, and so on).
- **Geometry:** [The Geometry Nodes](#).
- **Materials:** Material nodes.
- **Mesh:** Mesh nodes (see [Meshing](#)).
- **Physics interfaces:** except for the default nodes, the nodes for physics interfaces (such as material models, boundary conditions, domains, edges, points, and sources) can be moved within the physics interface branches (see [The Physics Interfaces](#)).
- **Study:** Study and study step nodes can be moved (see [Study and Study Step Types](#)).
- **Results:** the order of the nodes can be rearranged within each of the subbranches (Derived Values, Tables, Plot Groups, Export, and Reports). Exceptions under the Export node are the Plot, Mesh, and Table nodes (see [Results Analysis and Plots](#)).

Copying, Pasting, and Duplicating Nodes

It is possible to copy and paste many of the nodes in the Model Builder to create additional nodes with identical settings. Some nodes can also be duplicated underneath the original node. You can also move, copy, and duplicate nodes using “drag-and-drop” of nodes in the Model Builder.

Duplicate (⊕) is a convenient way to copy and paste in one step. In other words, it combines the **Copy** and **Paste** functions. When nodes are duplicated, the COMSOL Multiphysics software adds identical nodes underneath the original nodes on the same branch. You can duplicate most but not all nodes.

Nodes that can be copied (and duplicated) include the following:

- Functions, which are possible to copy from one **Definitions** or **Global Definitions** branch to another. Also see [Functions](#) and [Global Definitions, Geometry, Mesh, and Materials](#).
- Physics feature nodes, which can be copied within the same physics interface or to another identical physics interface. Also see [The Physics Interfaces](#).
- Geometry sequences, for which there are two ways to copy and paste geometry objects. Using the [Transforms>Copy](#) operation (that keeps the nodes linked to one another), or a standard copy and paste (see [Copying and Pasting Geometry Objects](#)). It is also possible to copy, paste, and duplicate nodes corresponding to operation features, such as the [Union](#) node.
- Study steps, which are possible to copy from one **Study** branch to another. Also see [Studies and Solvers](#).
- Plot nodes, which are possible to copy from one plot group to another. Also see [Plot Groups and Plots](#).

The copied object must be pasted into a model component with the same space dimension. For example, a [Sphere](#) can only be pasted into a 3D model.

HOW TO COPY, PASTE, OR DUPLICATE NODES

- On the Quick Access Toolbar (Windows users) or from the main **Edit** menu (macOS and Linux users), click [Copy](#) () , [Paste](#) () , or [Duplicate](#) () .
- Right-click a node and select [Copy](#), [Paste](#), or [Duplicate](#).
- To paste a node, and after selecting [Copy](#), click the parent node and right-click to select [Paste Heat Flux](#) to paste a copied node (a Heat Flux node in this case) to the parent node's branch.
- Create a copy of a node by Ctrl-clicking it and dragging a copy to an applicable location. A small plus sign at the cursor indicates that you drag a copy of the selected node.
- Ctrl-click and drag a duplicate to an applicable location. A small plus sign at the cursor indicates that you drag duplicates of the selected nodes.

Undoing and Redoing Operations

Undo is not possible for nodes that are built directly, such as geometry objects, solutions, meshes, and plots.

It is possible to undo the last operation for operations like adding, disabling, moving, and deleting nodes in the **Model Builder** as well as changing values in the **Settings** window. You can undo or redo several successive operations.

To undo the last operation or redo an undone operation:

- On the Quick Access Toolbar (Windows users) or from the main **Edit** menu (macOS and Linux users), select or click [Undo](#) () or [Redo](#) () .
- Press Ctrl+Z (undo) or Ctrl+Y (redo).

- [Copying, Pasting, and Duplicating Nodes](#)
- [Clearing Sequences and Deleting Sequences or Nodes](#)
- [Disabling or Enabling Nodes](#)

Going to the Source Node

In the **Settings** window for many nodes, other nodes can be referenced in the model tree such as a component, solution, study or study step, or data set, which provide data to the node where they are referenced.

Nodes where you refer to other nodes include plot groups, data sets, and solvers; in such nodes' **Settings** windows, click the **Go to Source** button () to move to the node that the selection in the list next to the button refers to.

- Settings and Properties Windows for Feature Nodes
 - Studies and Solvers
 - Results Analysis and Plots
-

Clearing Sequences and Deleting Sequences or Nodes

You can change the contents, and actions, of the sequences in the model tree by clearing a meshing sequence or solution under a solver configuration, or delete nodes in the Model Builder.

Undo is not possible for nodes that are built directly, such as geometry objects, meshes, solutions, and plots.

CLEAR OR DELETE A MESH

Use a **Clear** function to keep the nodes and be able to recreate the mesh by rebuilding the meshing sequence.

Under the **Component** node where you want to clear or delete the mesh:

- In the **Mesh** toolbar, click **Clear Mesh** () or right-click the **Mesh** node and select **Clear Mesh** ().
- To delete a meshing sequence, in the **Mesh** toolbar click **Delete Sequence** () or right-click the **Mesh** node and select **Delete Sequence** ().
- If you have a model geometry with several meshes, you can clear all meshes at the same time. From the **Mesh** toolbar, click **Clear All Meshes** ().

CLEAR OR DELETE A SOLUTION

Use a **Clear** function to keep the nodes and be able to recreate the solution by computing the solution again.

- To clear a set of solutions under a specific study, from the **Study** toolbar, click **Clear Solutions** () or right-click the **Study** node and select **Clear Solutions** ().
- To delete all solver nodes, right-click the **Solver Configurations** node and select **Delete Configurations** (). You can also choose whether or not to remove the Results nodes (data sets and plots, for example) associated with the solver configuration.
- If you have a model geometry with several studies, you can clear all solutions in all studies at the same time. From the **Study** toolbar, click **Clear All Solutions** ().

DELETE NODES

- To delete selected nodes, right-click the nodes and select **Delete** () or press Del (the Delete key). Confirm the deletion of nodes for it to take effect. Also see [Clear or Delete a Mesh](#).

- To delete a geometry sequence, in the **Geometry** toolbar click **Delete Sequence** () or right-click the **Geometry** node and select **Delete Sequence** (). You cannot use the **Undo** command.
- To delete geometry objects or entities, in the **Geometry** toolbar click **Delete** () or right-click **Geometry** and select **Delete** (). Or select objects in the **Graphics** window, and click the **Delete** button () in the **Graphics** window toolbar.

If you use the **Delete** button to delete objects, the software deletes the selected objects that correspond to primitive features by deleting their nodes from the geometry sequence. If you delete objects that do not correspond to primitive features or if you delete geometric entities, a **Delete Entities** node appears in the sequence.

Disabling or Enabling Nodes

A disabled node does not take part in the evaluation of a sequence; see [Figure 3-6](#). Some nodes, such as container nodes and default nodes in the physics interfaces (see [Physics Interface Default Nodes](#)), cannot be disabled (or deleted). When this is the case, the context menu does not have these options available. You can use Shift-click and Ctrl-click to select multiple nodes that you want to delete, disable, or enable.

- To disable selected nodes, right-click and select **Disable** () or press F3. The nodes are unavailable (dimmed) in the model tree to indicate that they are disabled. For a geometry or meshing sequence, disabled nodes do not affect the finalized geometry or mesh.
- To enable disabled nodes, right-click and select **Enable** () or press F4.

Instead of disabling and enabling variables and physics nodes to simulate different analysis cases (using different boundary conditions or sources, for example), use the selection of variables and physics interfaces in the study steps' **Physics and Variables Selection** sections, or use *load cases* for solving cases with varying loads or constraints. See [Physics and Variables Selection](#) and [Using Load Cases](#).

Modeling Guidelines

To model large-scale problems and for successful modeling in general, the COMSOL Multiphysics software makes it possible to tune solver settings and to use symmetries and other model simplifications to reach a solution or — failing that — interrupt the solution process to retrieve a partial solution. This section provides some tips and guidelines when modeling.

Selecting Physics Interfaces

When creating a model in COMSOL Multiphysics, you can select a single physics interface that describes one type of physics or select several physics interfaces for multiphysics modeling and coupled-field analyses.

MODELING USING A SINGLE PHYSICS INTERFACE

Most physics interfaces contain Stationary, Eigenvalue, and Time Dependent (dynamic) study types. As already mentioned, these physics interfaces provide features and windows where you can create models using material properties, boundary conditions, sources, initial conditions, and so on. Each physics interface comes with a template that automatically supplies the appropriate underlying equations.

If you cannot find a physics interface that matches a given problem, try one of the interfaces for PDEs, which makes it possible to define a custom model in general mathematical terms using equation-based modeling. Indeed, the COMSOL Multiphysics software can model virtually any scientific phenomena or engineering problems that originate from the laws of science.

MULTIPHYSICS MODELING USING MULTIPLE PHYSICS INTERFACES

When modeling real-world systems, you often need to include the interaction between different kinds of physics: *multiphysics*. For instance, an electric current produces heat, and the properties of an electronic component such as an inductor vary with temperature. To solve such a problem, combine two or several physics interfaces into a single model using the program’s multiphysics capabilities. For the example just mentioned, you can use the predefined Joule Heating multiphysics coupling, which is a combination of the Electric Currents and Heat Transfer interfaces. This way you create a system of two PDEs with two dependent variables: V for the electric potential and T for the temperature. There are many other predefined multiphysics couplings that combine two or more coupled physics interfaces for common multiphysics applications. If you have added physics interfaces for which predefined multiphysics couplings exist, they are available in the **Add Multiphysics** window (see [The Add Multiphysics Window](#)).

You can also combine physics interfaces and equation-based modeling for maximum flexibility.

To summarize the proposed strategy for modeling processes that involve several types of physics: Look for physics interfaces suitable for the phenomena of interest. If you find them among the available physics interfaces, use them; if not, add one or more interfaces for equation-based modeling.

When coupling multiple physics interfaces in a multiphysics model (without using a predefined multiphysics interface), the couplings can occur in domains and on boundaries. The COMSOL Multiphysics software recognizes some common multiphysics couplings, which then appear under the **Multiphysics** node. The program also automatically identifies potential *model inputs* for quickly forming couplings between physics interfaces. For example, a velocity field from fluid flow is a model input for convective heat transport in heat transfer. In that case, the model input automatically transfers the velocity field from the fluid to the heat transfer part.

Using Symmetries

By using symmetries in a model you can reduce its size by half or more, making this an efficient tool for solving large problems. This applies to the cases where the geometries and modeling assumptions include symmetries.

The most important types of symmetries are axial symmetry, symmetry planes or lines, and antisymmetry planes or lines:

- *Axial symmetry* is common for cylindrical and similar 3D geometries. If the geometry is axisymmetric, there are variations in the radial (r) and vertical (z) direction only and not in the angular (θ) direction. You can then solve a 2D problem in the rz -plane instead of the full 3D model, which can save considerable memory and computation time. Many physics interfaces are available in axisymmetric versions and take the axial symmetry into account. During postprocessing, you can revolve the 2D axisymmetric solution to view the results in 3D.
- *Symmetry and antisymmetry planes or lines* are common in both 2D and 3D models. *Symmetry* means that a model is identical on either side of a dividing line or plane. For a scalar field, the normal flux is zero across the symmetry line. In structural mechanics, the symmetry conditions are different. *Antisymmetry* means that the loading of a model is oppositely balanced on either side of a dividing line or plane. For a scalar field, the dependent variable is 0 along the antisymmetry plane or line. Structural mechanics applications have other antisymmetry conditions. Many physics interfaces have symmetry conditions directly available as nodes that you can add to the model tree.

To take advantage of symmetry planes and symmetry lines, all of the geometry, material properties, and boundary conditions must be symmetric, and any loads or sources must be symmetric or antisymmetric. You can then build a model of the symmetric portion, which can be half, a quarter, or an eighth of the full geometry, and apply the appropriate symmetry (or antisymmetry) boundary conditions.

Effective Memory Management

Especially in 3D modeling, extensive memory usage requires some extra precautions. First, check that you have selected an iterative linear system solver. Normally you do not need to worry about which solver to use because the physics interface makes an appropriate default choice. In some situations, it might be necessary to make changes to the solver settings and the model. For details about solvers, see the [Studies and Solvers](#) chapter.

ESTIMATING THE MEMORY USE FOR A MODEL

Out-of-memory messages can occur when the COMSOL Multiphysics software tries to allocate an array that does not fit sequentially in memory. It is common that the amount of available memory seems large enough for an array, but there might not be a contiguous block of that size due to memory fragmentation.

In estimating how much memory it takes to solve a specific model, the following factors are the most important:

- The number of node points
- The number of dependent and independent variables
- The element order
- The sparsity pattern of the system matrices. The sparsity pattern, in turn, depends on the shape of the geometry and the mesh but also on the couplings between variables in a model. For example, an extended ellipsoid gives sparser matrices than a sphere.

The MUMPS and PARDISO out-of-core solvers can make use of available disk space to solve large models that do not fit in the available memory.

You can monitor the memory use in the bottom-right corner of the COMSOL Desktop, where the program displays the amount of physical memory and total virtual memory used (see [Information About Memory Use](#)).

CREATING A MEMORY-EFFICIENT GEOMETRY

A first step when dealing with large models is to try to reduce the model geometry as much as possible. Often you can find symmetry planes and reduce the model to half, a quarter, or even an eighth of the original size. Memory usage does not scale linearly but rather polynomially (Cn^k , $k > 1$), which means that the model needs less than half the memory if you find a symmetry plane and cut the geometry size by half. Other ways to create a more memory-efficient geometry include:

- Avoiding small geometry objects where not needed and using Bézier curves instead of polygon chains.
- Using linear elements if possible (this is the default setting in some physics interfaces). See [Selecting an Element Type](#).
- Making sure that the mesh elements are of a high quality. Mesh quality is important for iterative linear system solvers. Convergence is faster and more robust if the element quality is high.
- Avoiding geometries with sharp, narrow corners. Mesh elements get thin when they approach sharp corners, leading to poor element quality in the adjacent regions. Sharp corners are also unphysical and can lead to very large (even infinite, in theory) stress concentrations.

INFORMATION ABOUT MEMORY USE

In the bottom-right corner of the COMSOL Desktop is information about how much memory COMSOL Multiphysics is currently using. The two numbers in [Figure 3-13](#) displayed as **921 MB | 1006 MB** represent the physical memory and the virtual memory, respectively. If you position the cursor above these numbers, the tooltip includes the numbers with the type of memory explicitly stated:

- The **Physical memory** number is the subset of the virtual address space used by COMSOL Multiphysics that is physically resident; that is, it is the amount of physical memory (RAM) in “active” use.
- The **Virtual memory** number is the current size of the virtual address space that COMSOL uses.

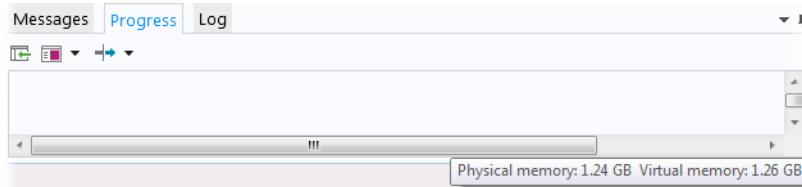

Figure 3-13: An example of memory use displayed in the COMSOL Desktop.

Selecting an Element Type

As the default element type for most physics interfaces and features, the COMSOL Multiphysics software uses first-order or second-order Lagrange elements (shape functions). Second-order elements and other higher-order elements add additional degrees of freedom on midpoint and interior nodes in the mesh elements. These added degrees of freedom typically provide a more accurate solution but also require more memory due to the reduced sparsity of the discretized system. For many application areas, such as stress analysis in solid mechanics, the increased accuracy of a second-order element is important because quantities such as stresses involve space derivatives and become constant within an element when using first-order elements.

COMSOL recommends that you use the default element types. For some applications, it might be possible to use a lower-order element than the default element type, but you must then use care to ensure that the important quantities are resolved.

For information about editing shape functions, see [Equation View](#).

Analyzing Model Convergence and Accuracy

It is important that the numerical model accurately captures local variations in the solution such as stress concentrations. In some cases you can compare your results to values from handbooks, measurements, or other sources of data. Many Applications Libraries examples are *benchmark models* that include comparisons to established results or analytical solutions.

If a model has not been verified by other means, a *convergence test* is useful for determining if the mesh density is sufficient. Here you refine the mesh and run the study again, and then check if the solution is converging to a stable value as the mesh is refined. If the solution changes when you refine the mesh, the solution is mesh dependent, so the model requires a finer mesh. You can use adaptive mesh refinement, which adds mesh elements based on an error criterion, to resolve those areas where the error is large. See the “Stresses and Strains in a Wrench” model in the *Introduction to COMSOL Multiphysics* book for an example of a convergence test.

For convergence, it is important to avoid singularities in the geometry.

Avoiding Singularities and Degeneracies in the Geometry

Achieving Convergence When Solving Nonlinear Equations

Nonlinear problems are often difficult to solve. In many cases, no unique solution exists. The COMSOL Multiphysics software uses a Newton-type iterative method to solve nonlinear systems of PDEs. This solution method can be sensitive to the initial estimate of the solution. If the initial conditions are too far from the desired solution, convergence might be impossible, even though it might be simple from a different starting value.

You can do several things to improve the chances for finding the relevant solutions to difficult nonlinear problems:

- Provide the best possible initial values.
- Solve sequentially and iterate between single-physics equations; finish by solving the fully coupled multiphysics problem when you have obtained better starting guesses.
- Ensure that the boundary conditions are consistent with the initial solution and that neighboring boundaries have compatible conditions that do not create singularities.
- Refine the mesh in regions of steep gradients.
- For convection-type problems, introduce artificial diffusion to improve the numerical properties. Most physics interfaces for modeling of fluid flow and chemical species transport provide artificial diffusion as part of the default settings.
- Scaling can be an issue when one solution component is zero. In those cases, automatic scaling might not work.
- Turn a stationary nonlinear PDE into a time-dependent problem. Making the problem time-dependent generally results in smoother convergence. By making sure to solve the time-dependent problem for a time span long enough for the solution to reach a steady state, you solve the original stationary problem.
- Use the parametric solver and vary a material property or a PDE coefficient starting from a value that makes the equations less nonlinear to the value at which you want to compute the solution. This way you solve a series of

increasingly difficult nonlinear problems. The solution of a slightly nonlinear problem that is easy to solve serves as the initial value for a more difficult nonlinear problem.

- The [residual](#) operator can provide insight into the location and development of the algebraic residual in models with convergence issues.

- [Stabilization Techniques](#)
- [Convergence Plots](#)
- [Introduction to Solvers and Studies](#)

Avoiding Strong Transients

If you start solving a time-dependent problem with initial conditions that are inconsistent, or if you use boundary conditions or sources that switch instantaneously at a certain time, you induce strong transient signals in a system. The time-stepping algorithm then takes very small steps to resolve the transient, and the solution time might be very long, or the solution process might even stop. Stationary problems can run into mesh-resolution issues such as overshooting and undershooting of the solution due to infinite flux problems.

Unless you want to know the details of the transients, start with initial conditions that lead to a consistent solution to a stationary problem. Only then turn on the boundary values, sources, or driving fluxes over a time interval that is realistic for your model.

In most cases, turn on your sources using a smoothed step over a finite time. What you might think of as a step function is, in real-life physics, often a little bit smoothed because of inertia. The step or switch does not happen instantaneously. Electrical switches take milliseconds, and solid-state switches take microseconds.

- [Introduction to Solvers and Studies](#)
- [Stationary and Time Dependent](#)

Physics-Related Checks and Guidelines

There are some important checks and guidelines that primarily apply to different areas of physics. Making these checks ensures that the model input is sufficient and increases the chances for successful modeling. See also the modeling sections of the documentation for the physics interfaces and the modules for more information related to modeling different physics.

FLUID FLOW AND TRANSPORT PHENOMENA

The following checks and guidelines primarily apply to fluid-flow modeling but also to modeling of other transport phenomena:

- If none of the boundary conditions include the pressure (most outlet conditions do, however), then you should specify the pressure at some point in the fluid domain. Without a specified pressure, the problem is underconstrained and it is difficult to get convergence.
- Make sure that the mesh is sufficiently fine, so that it contains at least 4–6 mesh elements across the thickness of a channel, for example.
- Make sure that the boundary conditions and the initial conditions match for time-dependent problems. For example, instead of starting with a full velocity on the wall, compared to a zero initial velocity field in the fluid,

ramp up the velocity with a smoothed step function or a ramp function that takes the inlet velocity from zero, which matches the initial value for the velocity field, to the full velocity. See [Avoiding Strong Transients](#).

- For fluid-flow models it is important to estimate the flow regime (laminar or turbulent) using the Reynolds number, for example. If the flow is in the turbulent regime, a turbulence model is typically required.

ACOUSTIC, STRUCTURAL, AND ELECTROMAGNETIC WAVE PROPAGATION

For models that describe wave propagation, it is important to fully resolve the wave in both time and space. In practice that means using a maximum mesh element size that provides about 10 linear or five second-order elements per wavelength and also, for transient simulations, a fixed time step that is small enough.

STRUCTURAL MECHANICS

The following checks and guidelines primarily apply to modeling of structural mechanics:

- Make sure that the model is fully constrained. At a minimum, you typically need to constrain the model to avoid all rigid-body movement, which for a 3D solid mechanics model means 6 constraints for three translations and three rotations. Otherwise, the solution is not well defined and does not converge.

The structural mechanics interfaces include a Rigid Motion Suppression feature, which eliminates all rigid-body movement. If you do not use that feature, it is not possible to add all 6 constraints in a single point, where you can constrain at most three translational degrees of freedom. For a 3D solid model you can use a “3–2–1 approach” to constrain 3 degrees of freedom at one point (a fixed constraint), 2 at another point, and 1 at a third point. To do so, select three convenient points (vertices) that are well separated. Then fix the first point in all three directions. Constrain the second point in the two directions orthogonal (normal) to the vector from point one to point two making sure that there is no restriction to deformation along the line from point one to point two. Finally, constrain the third point in a direction normal to the plane formed by the three points. To test this approach, the model should expand or contract under temperature loading and have small stresses throughout with no stress concentrations. The corresponding minimum constraints for a 2D model are a fixed constraint at one point for the 2 translational degrees of freedom and an additional constraint in one direction at another point to constrain the single rotational degree of freedom.

- Consider if you can assume that the material is linear elastic and that the deformations are small. If not, consider using a nonlinear material model.
- Avoid sharp corners in the geometry, which are unphysical and lead to unbounded stress concentrations.

Results With Unphysical Values

WHERE AND WHY DO UNPHYSICAL VALUES APPEAR?

In some models small unphysical values can occur due to numerical artifacts or other model-related reasons.

Examples include:

- Negative concentrations in mass transfer.
- A temperature that is slightly higher than the initial condition in time-dependent heat transfer studies.
- Small reaction forces that appear in unloaded directions in structural mechanics models.
- Small negative gaps in a contact analysis.
- Small negative effective plastic strain values.
- Stresses above the yield limit for an ideally plastic material in solid mechanics.

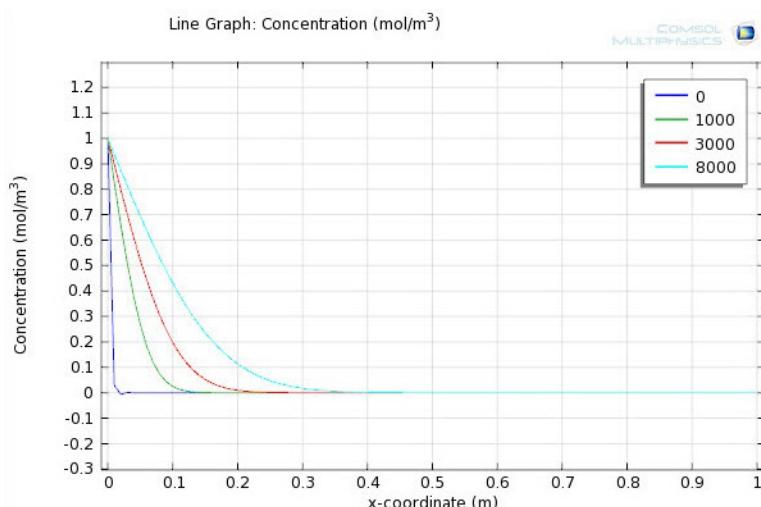

Some reasons for why these unphysical values occur:

- Numerical noise is a common cause. When the values of the dependent variables approach zero, the numerical noise can become relatively significant and cause some of the results to be slightly negative even if that is not physically possible.
- Interpolation and extrapolation of values can cause some values to become unphysical. Take care when using interpolated data or a piecewise polynomial function to define a temperature-dependent material property, for example. If you allow extrapolation outside of the defined range of input values, the material property values may not be valid. Also, results for an elastoplastic material are correct (within some tolerance) at the integration points (Gauss points) inside the finite elements, but values might become unphysical when extrapolating the data to the element boundaries.

The Plasticity feature is available as a subnode to a Linear Elastic Material with the Nonlinear Structural Materials Module.

- Discontinuities in the model is another source of, for example, small negative concentrations due to a discontinuous initial value. With an initial value that is zero along a boundary for convective transport models, for example, the physical interpretation is an initially sharp, gradually diffusing front moving away from the boundary. However, for the default shape function (second-order Lagrange elements), only continuous functions are admissible as solutions. COMSOL then modifies the discontinuous initial value before the time stepping can begin. This often results in a small dip in the solution at the start time. In the example model that the following figure shows, the concentration is locally slightly negative at $t = 0$:

- Lack of mesh resolution is another cause of unphysical values such as negative concentrations. The resulting convergence problems are often the underlying issue when negative concentrations are observed in high convection regimes (high Peclet number) and in those with large reaction terms or fast kinetics (high Damkohler number).
- Incorrect physics in the model can also cause these types of problems. For mass transfer, for example, the use of a constant sink in a reaction term is an approximation that only works for large concentrations. When the concentration reaches zero, the reaction term continues to consume the species, finally resulting in a negative concentration.

AVOIDING UNPHYSICAL VALUES

This section contains some ways to avoid computing or displaying unphysical values:

- In some cases it is possible to add a baseline to the dependent variable so that the numerical noise does not affect the solution in the same way as when the values of the dependent variable approach zero. This scaling is not possible with, for example, a reaction term that depends on the concentration because then the scale and origin do matter.
- Avoid discontinuities in the model using, for example, smoothed step functions.
- Formulate logarithmic variables as a way of eliminating mesh resolution problems and negative dips using the logarithm of the original dependent variable (the concentration, for example) as the dependent variable. The reason for this is that a linearly varying mesh sometimes does not capture the exponential behavior of the changes in the dependent variable. Modeling the logarithm of the dependent variable also ensures that the real concentration, for example, cannot become negative during the solution process.
- Avoid displaying small unphysical values due to numerical noise by clipping the values for the plot. You can do this by plotting, for example, $c^*(c>0)$ instead of c , which evaluates to 0 everywhere where c is smaller than 0. You can also adjust the range of the plot data and colors to only show nonnegative values. Parts of the plots where values are outside the range then become empty.
- It can also be useful to check how the mesh affects the solution by refining the mesh and checking if the problem with unphysical values gets better or worse. If it gets better, then continue to refine the mesh. If it gets worse, you probably need to check the physics of the model.

Multiphysics Modeling Approaches

The ability to create multiphysics models — those with more than one type of physics or equation such as coupled-field problems — is one of the most powerful capabilities of COMSOL Multiphysics. In such a model, the software can solve all the equations, taken from various areas of physics, as one fully coupled system.

Within the COMSOL software you can choose from several ways to approach multiphysics modeling and coupled-field analysis, including predefined multiphysics interfaces, predefined multiphysics couplings, and manually setting up multiphysics couplings using model inputs or expressions that include dependent variables or other expressions from another physics interface.

In this section:

- [Creating a Multiphysics Coupling](#)
- [Advantages of Using the Multiphysics Coupling Features](#)
- [The Add Multiphysics Window](#)
- [The Multiphysics Branch](#)
- [Uncoupling a Multiphysics Coupling](#)
- [Model Inputs and Multiphysics Couplings](#)

Creating a Multiphysics Coupling

There are two fundamental ways to create and use multiphysics couplings: using [Predefined Multiphysics Interfaces](#) or [Adding Physics Interfaces Sequentially](#) and then creating the multiphysics couplings using [The Add Multiphysics Window](#) or adding them suing [The Multiphysics Branch](#) or manually in the physics interface settings by using a model input or by directly typing an expression using a dependent variable from another physics interface, for example.

PREDEFINED MULTIPHYSICS INTERFACES

The [Joule Heating Interface](#) is an example of a predefined multiphysics interface. Many other multiphysics interfaces are available depending on the products included in your COMSOL license. After **Joule Heating** is selected from [The Model Wizard](#), the **Heat Transfer in Solids** interface, the **Electric Currents** interface, and a **Multiphysics** node, including the default features applicable to the multiphysics coupling (**Electromagnetic Heat Source**, **Boundary Electromagnetic Heat Source**, and **Temperature Coupling**), are displayed under the **Added physics interfaces** list as in [Figure 3-14](#). [Figure 3-15](#) shows you what is included in the Model Builder when a predefined multiphysics interface is added. Compare to [Figure 3-16](#) where individual physics interfaces are added, and these features are initially accessible only from the context menu. There can also be moving mesh nodes added as part of a multiphysics interface; they then appear under **Definitions** in the **Added physics interfaces** list.

You can add physics interfaces when you start creating the model with [The Model Wizard](#) or at any time with [The Add Physics Window](#).

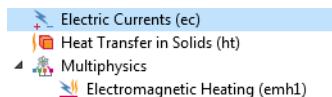

Figure 3-14: When Joule Heating is selected in the Model Wizard, the default physics interfaces and coupling feature are displayed under Added physics interfaces.

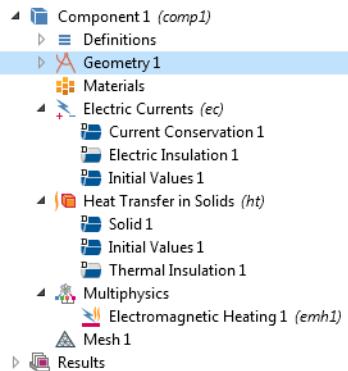

Figure 3-15: An example of what is added to the Model Builder when Joule Heating is selected in the Model Wizard. The Electromagnetic Heating feature is automatically included under the Multiphysics node.

ADDING PHYSICS INTERFACES SEQUENTIALLY

An empty **Multiphysics** node is added automatically when two (or more) physics interfaces are set up in a model and when there is the possibility to couple the physics interfaces. In other words, if you add physics interfaces one at a time, and the software identifies these physics interfaces as being of the multiphysics category, the **Multiphysics** node is automatically added to the Model Builder. The relevant features are made available from the context menu (right-click the **Multiphysics** node) as well as from the **Physics** toolbar, in the **Multiphysics** menu. See Figure 3-16. You can also add predefined multiphysics couplings from the **Add Multiphysics** window (see [The Add Multiphysics Window](#)), which then adds all the necessary multiphysics coupling node under the **Multiphysics** node. Using a sequential approach makes it possible to analyze and validate one physics at the time before solving the full multiphysics model.

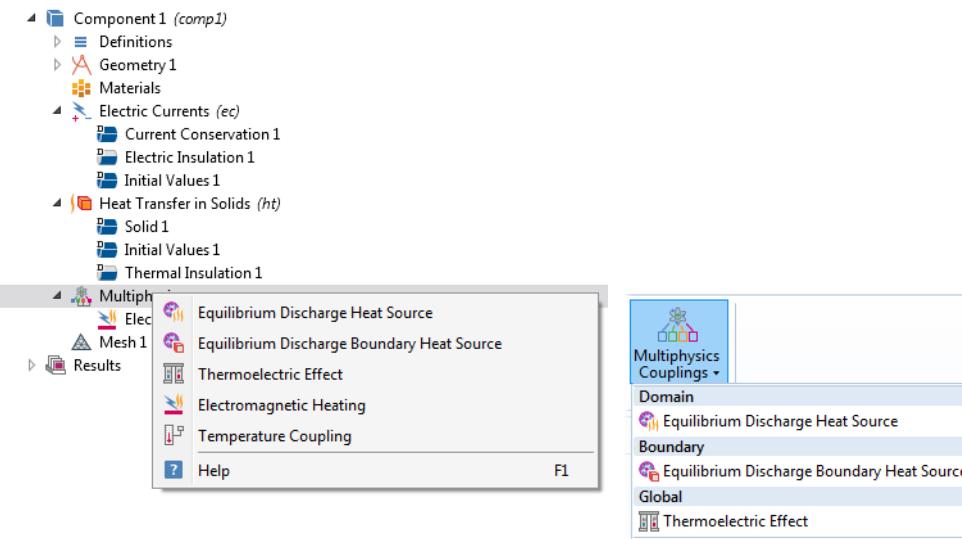

Figure 3-16: An example of when a Multiphysics node is automatically added to the model. The specific multiphysics features are made available from the context menu (left) or (partially shown here) Physics toolbar, Multiphysics menu (right) based on the physics interfaces in the model. The difference when the predefined Joule Heating interface is added is that these features are included under Multiphysics and there are some modified settings automatically applied. In either case, the available features depend on the add-on module license.

Advantages of Using the Multiphysics Coupling Features

One advantage of using the predefined multiphysics couplings is that specific or modified settings are included with the physics interfaces and the coupling features. But if physics interfaces are added one at a time, followed by the coupling features, these modified settings are not automatically included.

For example, if you add single Electric Currents and Heat Transfer in Solids interfaces to the Model Builder, the COMSOL Multiphysics software adds an empty **Multiphysics** node. The applicable multiphysics couplings are then available as subnodes that you can add. Even more convenient, you can choose the predefined Joule Heating multiphysics coupling, for example, which then adds the **Electromagnetic Heat Source**, **Boundary Electromagnetic Heat Source**, and **Temperature Coupling** nodes under the **Multiphysics** node, so that you do not need to remember which multiphysics coupling nodes to add for a specific type of multiphysics. See [The Add Multiphysics Window](#).

In general, it is useful to use any type of multiphysics coupling because you can turn multiphysics on and off (that is, enable and disable features), giving you more flexibility to test and observe multiphysics effects.

Even if you do not start with a predefined coupling, another benefit of this approach is that you are no longer constrained by the use of specific physics interfaces, nor do these have to be added in any specific order. With the new coupling approach, the order in which physics interfaces are added does not matter for the end result.

An example of this is if you start modeling by adding a Heat Transfer in Solids interface. As you continue to build the model, you add an Electric Currents interface. At this stage of the process, you have defined several boundary conditions, chosen materials, or experimented with other settings. You may have also solved the model successfully at this point and now you want to continue building on this design. The COMSOL Multiphysics software recognizes this and adds a **Multiphysics** node, which you can right-click to access and add multiphysics couplings.

For multiphysics interfaces that consist of participating physics interfaces, the default solver settings use a segregated solver approach with one segregated step for each physics interface and each of these steps calling an iterative solver. These solver settings are suitable for large models, but if possible, a fully-coupled solver approach using direct solvers can be more robust. You can switch to such solver settings by right-clicking the **Study** node and choosing **Show Default Solver**. Then the solver nodes that the multiphysics interface specifies appear under the **Solver Configuration** node, and you can right-click the solver node to add a **Fully Coupled** solver node to replace the **Segregated** node, for example.

For some multiphysics interfaces, a side effect of adding physics interfaces one at a time is that two study types — Frequency-Stationary and Frequency-Transient — are not available for selection until *after* at least one coupling feature is added. In this case, it is better to first add an **Empty Study**, then add the coupling features to the **Multiphysics** node, and lastly, right-click the **Study** node to add the study steps as needed.

The Add Multiphysics Window

The **Model Wizard** and the **Add Physics** window contain predefined multiphysics interfaces, which typically add two or more physics interfaces and some coupling features that define the multiphysics couplings between those physics interfaces. When building a model, it is often best to start with a single physics before adding other physics and the multiphysics couplings that connect them. To add any applicable predefined multiphysics coupling in a model, open the **Add Multiphysics** window () by right-clicking a **Component** node or from the **Physics** ribbon toolbar. The predefined multiphysics that the selected physics interfaces support then appears in the tree. Choose the wanted multiphysics couplings and add them to the component under **Multiphysics** by pressing Enter, clicking the **Add to Component** button (), or right-clicking the multiphysics coupling and choosing **Add to Component**. The required multiphysics coupling nodes are then added to the model, and the participating physics interfaces are modified by setting the correct physics property values and adding any needed features for the selected multiphysics couplings.

You control which multiphysics couplings that appear under **Select the physics interfaces you want to couple**. You can clear and select all physics interfaces in the current component. By default, all physics interfaces are selected and appear with a check mark () in the **Couple** column. The available multiphysics couplings depend on which COMSOL Multiphysics products your license includes. If no multiphysics coupling is available, **No Coupling Features Available for the Selected Physics Interfaces** appears. You must select at least two physics interfaces for any multiphysics couplings to appear. With more than two physics interfaces in the component, any combination of two or sometimes more physics interfaces typically results in a different set of available multiphysics couplings, whereas most combinations of three or more physics interfaces result in no available multiphysics couplings.

The existing **Studies** are listed under **Multiphysics couplings in study**. By default, the studies appear with a check mark () in the **Solve** column, which indicates that the study solves for the equations that the multiphysics couplings add. Click in the column to clear the check mark and exclude the equations in the multiphysics coupling from that study. Some multiphysics couplings do not add any extra equations and are then not affected by this setting.

The Multiphysics Branch

The **Multiphysics** branch () contains, or has available, any physics features that are likely to be used as multiphysics coupling for a particular set of physics interfaces added to the Model Builder. See [Figure 3-16](#). There are no settings required for the node itself.

There are different approaches to the use of the multiphysics coupling feature. It is either predefined when you add a specific physics interface or it is automatically added when the software recognizes there is a logical coupling inherent in the model design. When it is added as part of a predefined coupling, the coupling features are also included under the **Multiphysics** node. Otherwise, all relevant coupling features are available from the context menu. Additional functionality is also based on the add-on modules.

Predefined multiphysics interfaces provide you with a quick entry point for common multiphysics applications. You can create the same couplings using any of the other methods for multiphysics modeling, and you can continue to add, modify, disable, and remove physics features or interfaces in a model when you start using one of the predefined multiphysics interfaces. If instead you decide to add physics interfaces sequentially, this approach is also useful as you can verify that each type of physics or equation gives the expected results before adding more complexity to the model by adding another physics interface, physics feature, or coupling fields.

For links to more information about the add-on modules and the multiphysics interfaces available go to www.comsol.com/comsol-multiphysics.

Uncoupling a Multiphysics Coupling

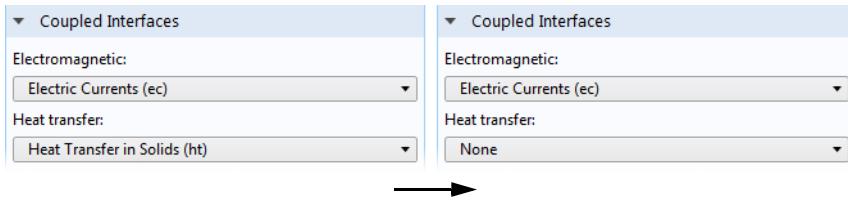

Figure 3-17: Uncoupling a predefined multiphysics coupling feature.

For each multiphysics coupling feature, for example the [Electromagnetic Heating](#), there is a section that defines the physics interface involved in the multiphysics coupling. By default, the applicable physics interface is selected in the lists to establish the coupling.

You can also select **None** from the lists to uncouple the node from a physics interface. If the physics interface is removed from the **Model Builder**, for example if a **Heat Transfer in Solids** interface is deleted, then the **Heat transfer** list for the **Electromagnetic Heating** reverts to **None** (Figure 3-17) as there is no interface to couple to.

If a physics interface is deleted and then added to the model again, and in order to re-establish the coupling, you need to choose the physics interface again from the lists. This is applicable to all multiphysics coupling nodes that would normally default to the once present interface.

Model Inputs and Multiphysics Couplings

Model inputs can appear in an equation or material model node's **Model Inputs** section. Model inputs are typically fields such as temperature and velocities that act as inputs for material models and model equations, but they can be any available physical property. They appear in the **Model Inputs** section if a material is defined so that a material property becomes a function of the temperature, for example. The COMSOL Multiphysics software connects the model input to an existing field (dependent variable) within the physics interface (but not to available fields in other physics interfaces). Common model inputs are always available. You can define scalar values for common model inputs under **Global Definitions** for use throughout the model (see [Common Model Inputs](#)).

For frequently used multiphysics couplings, predefined multiphysics coupling nodes are available under the **Multiphysics** node (see [The Multiphysics Branch](#)). The following part of this section is mostly useful for cases when such predefined couplings are not available.

With more than one physics interface in the model, coupling of the fields is easy: all applicable fields that can serve as inputs in another physics interface automatically appear in the other physics interface's **Settings** window's **Model Inputs** section. For example, with a Heat Transfer in Fluids (ht) interface and a Laminar Flow (spf) interface, you can select **Velocity field (spf)**, which the **Fluid Properties 1 {fp1}** node in the **Laminar Flow** branch defines, from the **Velocity field** list in the **Model Inputs** section of the **Settings** window for the **Fluid** node under **Heat Transfer in Fluids**. The velocity field from the Laminar Flow interface then becomes the velocity field for the convective heat transfer. You can also choose **Common model input** to use its value to define the velocity field, or choose **User defined** to enter a user-defined velocity field.

When you have selected a model input from one of the lists, click the **Go to Source** button () next to the list to move directly to the node in the other physics interface that provides the model input. If more than one node contribute to the model input, choose which one to go to in the **Contributing Entities** dialog box. Then click **OK** to move to the selected node.

You can also, if you have selected **Common model input**, click the **Create Model Input** button () to create a local **Model Input** node in the current component (see [Model Input](#)) for defining a model input for some or all of the geometry in the current component, overriding the common model input.

By default, the **Model Input** section in the **Fluid Properties** node under the **Laminar Flow** node is empty. But if you, for example, add a temperature-dependent material property such as the dynamic viscosity, a **Temperature** list appears in the **Model Input** section where you can explicitly choose the **Temperature (ht)** field or use a user-defined temperature or a **Common model input** like any other model input.

A list in the **Model Inputs** section becomes unavailable if the physics itself defines the field because it is then automatically connected to that field. For example, with a Heat Transfer in Fluids (ht) interface the **Temperature** list is unavailable in the **Fluid** node under **Heat Transfer in Fluids**. This automatic connection selects the **Temperature (ht)** field. As long as the list is unavailable, you cannot change it. If you want to use another temperature field or an expression, you first make the list editable by clicking the **Make All Model Inputs Editable** button (). Using this option can be useful in order to, perhaps temporarily, break a multiphysics coupling and use a user-defined value instead to, for example, investigate a simulation that does not converge.

For this type of fluid-thermal coupling, the **Multiphysics** branch provides a predefined **Fluid Coupling** node, which provides an easy way to set up this coupling without having to explicitly specify the model input.

See *Joule Heating of a Microactuator* for an example of combining the Electric Currents and Heat Transfer in Solids interfaces through a Joule Heating multiphysics interface (Application Library path **COMSOL_Multiphysics/Multiphysics/thermal_actuator_jh**).

Specifying Model Equation Settings

The fundamental mathematical model, representing the physics in a physics interface, is contained in physics nodes with selection on the same space dimension as the physics itself. The first node under a physics branch is of this type and sets up default equations where the physics interface is active. These equations are controlled by specifying:

- Material properties, which COMSOL Multiphysics uses as coefficients in the equations
- A coordinate system, which makes it possible to specify anisotropic material properties and vectors in a more convenient coordinate system than the global Cartesian coordinate system.
- A material model (a mathematical model for a constitutive relation, for example), which selects an equation suitable for a given type of material

Not all physics features allow anisotropic materials or more than one material model. Therefore, these settings cannot be present.

The default node uses the same material model, and thus the same equations, everywhere. Material properties can vary between different parts of the feature's selection, if the property is specified as taken **From material**. Add additional nodes to use different material models for different parts of the geometry, or to use different **User defined** material property values.

In equation-based modeling, provided by the Mathematics branch interfaces, the form of the equation is fixed for each particular node type. Each given equation form contains a number of free PDE coefficients, which you can be specify in the settings to define the specific equation that you want to solve.

Equation-Based Modeling

Specifying Equation Coefficients and Material Properties

To specify an equation coefficient or a material property, enter a value or an expression directly in the corresponding field. Such expressions can contain:

- Numerical values.
- Units (see [Using Units](#)).
- Built-in [Mathematical and Numerical Constants](#).
- Spatial coordinates, time, and the dependent variables in any physics feature in the model as well as the spatial derivatives and time derivatives.
- [Physical Constants](#) — built-in universal physical constants.
- User-defined parameters, variables, coupling operators, and functions, including external functions and MATLAB® functions (requires the COMSOL LiveLink™ for MATLAB®). See [Operators, Functions, and Constants](#).
- Built-in functions and operators such as `d` and `mean`.

You can use these types of variables, constants, functions, and operators in all settings for the physics interfaces; many types of variables are also available anywhere in the model.

In most cases where you can enter an expression, you can press Ctrl+Space (or Ctrl+/) to choose from a number of applicable variables, parameters, functions, operators, and constants that you can insert into the expression at the position of the cursor.

Modeling Anisotropic Materials

Anisotropic materials respond differently to an excitation depending on its direction. Because excitations are generally vectors and the corresponding response is a vector density, material properties are usually rank-2 tensor densities. For example, the following material properties are anisotropic tensor densities: diffusion coefficient, permittivity, thermal conductivity, and electrical conductivity.

These properties are, in principle, specified in matrix form and defined by their components in the coordinate system selected in the node settings. At most four components are used in 2D and at most nine components in 3D. When the material contains symmetries, you can specify only a few coefficients, which are expanded to a matrix using the following patterns:

- **Isotropic** (the default) — enter only one value c .

$$C = \begin{bmatrix} c & 0 & 0 \\ 0 & c & 0 \\ 0 & 0 & c \end{bmatrix}$$

- **Diagonal** — enter the diagonal components for an anisotropic material with the main axes aligned with the model's coordinate system.

$$C = \begin{bmatrix} c_{11} & 0 & 0 \\ 0 & c_{22} & 0 \\ 0 & 0 & c_{33} \end{bmatrix}$$

- **Symmetric** — enter a symmetric matrix using the diagonal components and the upper off-diagonal components.

$$C = \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{12} & c_{22} & c_{23} \\ c_{13} & c_{23} & c_{33} \end{bmatrix}$$

- **Anisotropic** — enter the full 2-by-2 (2D) or 3-by-3 (3D) matrix for an anisotropic material:

$$C = \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix}$$

Specifying Initial Values

An **Initial Values** node is added by default to each physics interface.

In some types of analyses initial values must be provided:

- As the initial condition for a time-dependent analysis.
- As an initial guess for the nonlinear stationary solver.
- As a linearization (equilibrium) point when solving a linearized stationary model or when performing an eigenvalue study.

To enter initial values, in the **Model Builder**, click the **Initial Values** node under a physics interface node. In the **Settings** window, enter the **Initial Values** for all dependent variables (fields) in the physics interface. The default initial values are usually zero.

For some physics interfaces you can also enter initial values for the first time derivative of the dependent variables. These are used when solving time-dependent problems containing second time derivatives (wave-type applications). Like other default settings, these initial values apply to all domains where no other values are specified.

To use different initial values in different domains, add another **Initial Values** node from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or right-click to access the context menu (all users).

See [Dependent Variables](#) for more information about handling and plotting initial values.

Equation View

Equation View () is a subnode available for all physics feature nodes. To display these subnodes, click the **Show** button () and select **Equation View** from the **Model Builder**.

The **Settings** window for **Equation View** contains detailed information about the implementation of each physics feature: variables, shape functions, weak-form equation expressions, and constraints.

To update the values in the **Settings** window for **Equation View** to reflect the latest changes in a physics feature, click the **Refresh Equations** button () in the **Settings** window's toolbar.

Editing the predefined expressions for variables, equations, and constraints means that the equations are altered and that COMSOL Multiphysics solves the model using the new expressions.

You can edit the expressions or values of variables, weak-form expressions, and constraints in the corresponding tables under **Variables**, **Weak Expressions**, and **Constraints**, respectively. This makes it possible to introduce custom changes to the equations and variable definitions. If the expression that defines a variable, for example, does not fit inside of the text field, a tooltip displays the entire expression. Press Ctrl+Space (or Ctrl+/) or use the **Insert Expression** button () below the tables to choose from a number of applicable variables, parameters, functions, operators, and constants that you can insert into the expression at the position of the cursor. In the table of variables under **Variables**, you can click any of the column headers to sort the table contents alphabetically based on the contents of that column (in ascending order; click again for descending order; click yet again to restore the original order).

For a changed definition of a variable or a change to a weak-form expression or constraint, a warning icon () appears in the leftmost column, and a small padlock is added to the lower-right corner of the icon for the physics node where you have made modifications in its equation view. To restore only the change in the selected variable, weak-form expression, or constraint, click the **Reset Selected** button () under the table in the **Variables**, **Weak Expression**, or **Constraints** section. To reset all changes in the equation view, click the **Reset All** button () in the **Settings** window's toolbar. If no changes remain, the padlock disappears from the corresponding physics node. An orange color for the expression that defines the variable is a warning that the unit of the expression does not match the expected unit for the variable that it defines. To store all information in the tables under **Variables**, **Shape Functions**, **Weak Expressions**, or **Constraints** to a text file, click the corresponding **Save to File** button ().

For information about the Equation displays available, see [Physics Nodes — Equation Section](#).

STUDY

From the **Show equation view assuming** list, choose **No study** or any of the available studies. The equation view of the parent feature is then recomputed with the assumption that the selected study step was solved. This operation also updates all children to the parent feature, so the lists in their equation views are also updated. When solving a study (or study step), the list also changes to represent the last computed study step. The default is **No study** and represents a default behavior, which computes the equations without any study type information. The equation form used is then undefined and depends on the physics that the parent feature belongs to. The equation view reverts to **No study** if you change some setting in the parent feature to indicate that the equation view no longer represent a specific study step.

VARIABLES

This section has a table with the variables that the physics node defines. The table includes these columns:

- **Name:** the name of the variable.
- **Expression:** the expression, using COMSOL syntax, that defines the variable.
- **Unit:** the unit for the variable (in the active unit system). If the unit of the expression does not match the unit of the variable, the expression is displayed in orange.
- **Description:** a description of the variable.
- **Selection:** the geometric entities (domains, boundaries, edges, or points) where the variable is defined (**Domain 1**, for example).
- **Details:** this column contains some details about the variable's behavior. See [About the Details Column](#) below.

If you click a single variable, its selection, as indicated in the **Selection** column, appears in the **Graphics** window.

SHAPE FUNCTIONS

This section has a table with the dependent variables that the physics node defines and their shape functions. This is primarily applicable to equation model nodes; for most physics nodes such as boundary conditions, the table is empty. The table has these columns:

- **Name:** the name of the variable.
- **Shape function:** the type of shape function (element) for the variable (for example, **Lagrange** for Lagrange elements, which are the most common elements).

Selecting an Element Type

- **Unit:** the unit for the variable (in the active unit system).
- **Description:** a description of the variable.
- **Shape frame:** the frame type (typically either a spatial or a material frame) for the shape function.
- **Selection:** the geometric entities (domains, boundaries, edges, or points) where the shape function is defined (**Domain 1**, for example).
- **Details:** This column contains some details about the shape function's behavior. See [About the Details Column](#) below.

WEAK EXPRESSIONS

This section has a table with the weak-formulation equation contributions that the physics node generates. The table consist of the following columns:

- **Weak expression**, the equation expressed in a weak formulation.
- **Integration order**, the order for the integration of the weak expression (see [integration order](#) in the *Glossary*). Polynomials of at most the given integration order are integrated without systematic errors. For smooth expressions, a sufficient integration order is typically twice the order of the shape function. For example, the default integration order for second-order Lagrange elements is 4.
- **Frame**, the frame type (typically either a spatial or a material frame) used when integrating the expression.
- **Selection**: the geometric entities (domains, boundaries, edges, or points) where the weak expression is defined ([Domain 1](#), for example).

Each equation contribution appears on its own row under **Weak expression**, but the order is not significant.

The PDE interfaces and the ODEs and DAEs interfaces do not display any weak expressions. They are either implemented using strong formulations, directly display the weak formulation, or define equations discretized in the time domain only.

CONSTRAINTS

This section has a table with the constraints that the physics node generates. This is typically the case for boundary conditions of constraint types, such as prescribed displacements, temperature, or velocities. Many other physics nodes do not generate any constraints, and the table is then empty. The table consists of the following columns:

- **Constraint**: the expression for the constraint.
- **Constraint force**: the expression that defines the associated constraint force, which is typically the test function of the constraint.
- **Shape function**: the type of shape function (element) for the constraint (for example, **Lagrange** for Lagrange elements).
- **Selection**: the geometric entities (domains, boundaries, edges, or points) where the constraint is defined ([Boundaries 1–5](#), for example).

ABOUT THE DETAILS COLUMN

The **Details** column shows some information about the behavior of variables and shape functions. For variables:

- An empty cell indicates that overlapping contributions are overridden.
- **+ operation** indicates that overlapping contributions are added.
- For some variables, **Meta** indicates that the variable definitions are not fully updated until you solve the model. It is therefore not possible to edit the expressions for such variables.
- In rare cases, other operations (*** operation**, for example) can occur.

For shape functions:

- **Slit** means that the shape function creates a slit for the degree of freedom.

Physics Nodes — Equation Section

For each physics node there is an **Equation** section always available on the **Settings** window. This has options to display mathematical equations applicable to the node.

Equation View

The display options available from the lists depend on the study types and other physics-specific factors. See [Figure 3-19](#) for an example comparing the equations that display for a **Stationary** or **Time Dependent** study for a **Heat Transfer in Solids** interface. Some **Settings** windows do not have any options and only display the relevant equation and other windows have additional sections that become available for the **Equation** display based on the study type selected.

Study and Study Step Types

Node Contributions Display a Dotted Line Under Part of the Equation

For all physics nodes (excluding the main physics interface node level), the equation that displays includes a dotted line underneath where the node's contribution is made to the equation. See [Figure 3-18](#) for an example where a section of the heat transfer equation is underlined, indicating where the **Solid** node contributes to it.

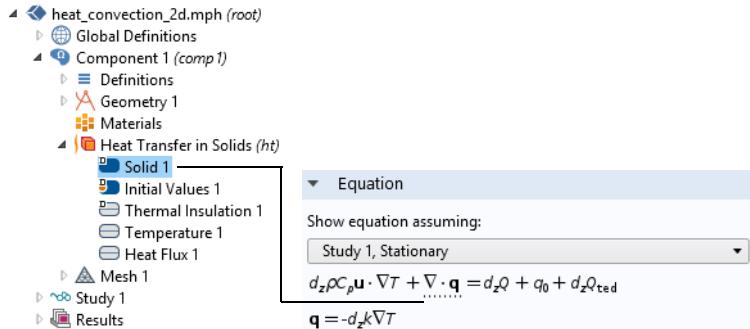

Figure 3-18: The Solid contribution to the equation for a 2D model.

Equation Form

When you add physics interfaces to a Component, the supported **Study types** are listed in the **Equation form** list. **Study controlled** is the default; select another option as needed. When the setting is **Study controlled**, the study controls the equation form — stationary or time dependent, for example — for the physics interface. In some cases, that equation form might not be compatible with the physics covered by the physics interface; the physics interface then uses its default equation form (typically, a stationary equation form). You can then instead choose one of the supported study types.

Show Equation Assuming

The **Show equation assuming** option is available by default when **Study controlled** is selected (or left as the default) as the **Equation form**. Options availability is based on the studies added and defined for the model.

For the following options — frequency and mode analysis frequency — you also have the option to use another frequency than the one used by the solver. This can be necessary if you need two different frequencies for two physics interfaces.

Frequency

This option is available if **Frequency domain** is selected as the **Equation form**. The default uses the frequency **From solver**. If **User defined** is selected, enter another value or expression (SI unit: Hz).

Mode Analysis Frequency

This option is available if **Mode Analysis** or **Boundary Mode Analysis** is selected as the **Equation Form**. Enter a value or expression in the field (SI unit: Hz). Specify a frequency (it is not present as a solver variable).

Port Name

This option is available with the RF Module **Electromagnetic Waves** interface and if **Boundary Mode Analysis** is selected as the **Equation Form**. Enter a value in the field (unitless).

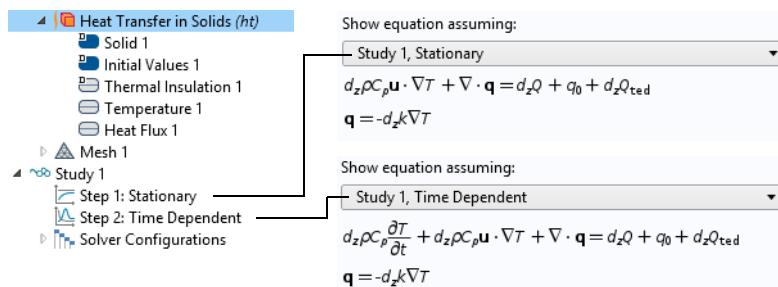

Figure 3-19: An example of the Equation section on a Heat Transfer interface. Selecting the study type updates the equation accordingly.

Boundary Conditions

In the interior of the selection where a physics feature is active, its behavior is governed by its model equations and material properties. *Boundary conditions* apply to the geometric entities separating this region from the unspecified outside and sometimes also to interior entities of the same dimension (interface conditions). Therefore, boundary conditions on a 3D solid object apply to the exterior surfaces of the solid and to interior surfaces embedded in the solid. On a shell geometry in 3D space, boundary conditions instead apply to the edges of the shell surface. In general, boundary conditions apply to geometric entities whose dimension is one less than the physics interface's dimension.

All physics interface branches that contain a default model equation node also contain a default boundary condition node. This boundary condition is active on all exterior boundaries of the physics' selection, except on the symmetry axis of axisymmetric 2D models. On interior boundaries, an implicit continuity condition applies, which makes the physics field (the temperature, for example) continuous across interior boundaries.

In physics interfaces defined on shells, for example, the domain equations are defined on 3D boundaries, and you define the interface conditions on edges as edge conditions rather than boundary conditions.

Boundary Condition Types

There are two fundamental ways to specify what is happening at a boundary, and two corresponding fundamental boundary condition types:

- *Flux conditions* specify how the surroundings affect and interact with the model at the boundary, often expressed as an applied force, flux, or current. This type of boundary condition is also called a *Neumann boundary condition*.
- *Constraints* specify the result of the interaction between the model and its surroundings, expressed as prescribed values of the dependent variables. This type of boundary condition is also called a *Dirichlet boundary condition*.

The two types are closely related because in a well-posed model, every flux condition results in some unique values of the dependent variables, and every constraint requires a unique flux to enforce the expected values. Which type of condition to use depends on what is known about the conditions at the boundary: if the flux is known, the model computes the dependent variables for you; if the values of the dependent variables are known, the model computes the flux.

FLUX CONDITIONS

Flux boundary conditions specify the component of a vector or tensor quantity in the direction normal to the boundary, per unit area of the boundary. Typical examples of flux conditions are the specification of:

- A **Boundary Load** in a solid model, which prescribes the stress acting on the boundary.
- **Heat Flux** in a heat transfer model, which prescribes the heat per unit area flowing into (or out of) the model across the boundary.
- A **Normal Current Density** in an AC/DC model, which prescribes the electrical current per unit area entering (or exiting) the model at the boundary.

There are also more advanced types of flux conditions, where the flux or force is calculated based on local values of dependent variables and other parameters. For example, a **Convective Heat Flux** boundary condition on a heated

body computes the heat flux based on a heat transfer coefficient and the temperature difference to the surroundings.

Convective Heat Flux requires the CFD Module or Heat Transfer Module.

In COMSOL Multiphysics, by convention, the force acting *on* the model or the flux *into* the model is specified. That is, specify how the surroundings affect the model and not how the model affects its surroundings. You can change the direction by reversing the sign before the numerical value of the force or flux.

CONSTRAINTS

Constraint boundary conditions specify the value of one or more dependent variables at the boundary, or a relationship between two or more dependent variables. Typical examples include specifying:

- A [Prescribed Displacement](#) of the boundary of a solid object.
- That the velocity is zero on a [Wall](#) boundary in a CFD model.
- The [Temperature](#) at the boundary of a heated solid.
- The [Electric Potential](#) on an electrode in an AC/DC model.

Examples specifying a relation between dependent variables include [Roller](#) conditions on solids and [Wall](#) conditions for slip flow.

Because constraint conditions generally specify the value of a dependent variable, they also provide a reference level for that variable, which a flux condition normally does not. In many types of physics, the model equations together with only flux boundary conditions uniquely describe the local behavior of the dependent variable, but leave the global level undefined. From a physical point of view, the absolute value of the dependent variables are often of less interest, but the existence of a single, unique, solution is essential for some solvers.

Therefore it is often necessary to apply at least one constraint condition in a model, to provide a global reference value for the dependent variables. For example, it is common to designate one of the electrodes in an AC/DC model as [Ground](#), which constrains the electric potential there to zero and gives a reference with which to compare other parts of the model.

In most physics features, the default boundary condition is of a *flux* type and does *not* fix a reference level for the dependent variable. Therefore, when solving certain study types (notably stationary studies), you must manually add at least one boundary condition of *constraint* type (or a point constraint) for the model to be well-defined.

SWITCHING OFF A CONSTRAINT

If you want to model a constraint that is active only for a certain period of time in a time-dependent simulation, for example, you can use the fact that a 0 constraint (or a Dirichlet boundary condition $u = u$) means that there is no constraint; instead, the boundary condition becomes a “no flux” or “insulation” condition. To implement such a time-limited constraint, you can use the `if` operator: for example, for a Dirichlet boundary condition,

`if(t<2,1,u)` means that for $t < 2$, u is equal to 1 but at $t = 2$ the boundary condition is turned off by setting $u = u$. For a Constraint node, the corresponding `if` statement is `if(t<2,1-u,0)`.

- Constraint Reaction Terms
- Weak Constraints
- Constraint Settings

Physics Interface Boundary Types

There are different types of boundaries for the physics interfaces, which all support different types of boundary conditions:

- Exterior boundaries, where most boundary conditions are applicable — see below.
- Interior boundaries, where special interface conditions can be applicable — see below.
- Axial symmetry boundaries, which are artificial boundaries representing the symmetry axis in axisymmetric models.

If a selection for a boundary condition node, for example, contains boundaries of a type that is not applicable or supported, the **Selection** list has (**not applicable**) next to those boundary numbers.

INTERIOR AND EXTERIOR BOUNDARIES

When specifying boundary and interface conditions, COMSOL Multiphysics differentiates between exterior and interior boundaries:

- An *exterior boundary* is an outer boundary of the modeling domain.
- A *interior boundary* is a dividing interface between two domains in the geometry.

If an equation or physics interface is deactivated in one domain, the interior boundary between the active and inactive domain becomes an exterior boundary for its variables because it then borders on the outside of the active domain for those fields. The boundaries of the inactive domain are then void.

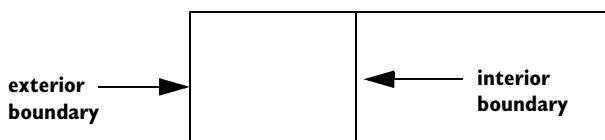

Figure 3-20: Examples of exterior and interior boundaries.

Continuity on Interior Boundaries

Unless a boundary condition is specified on interior boundaries (such as a contact resistance condition), the COMSOL Multiphysics software ensures continuity in the field variables across interior boundaries. For assembly geometries with identity pairs, select a **Continuity** node in the **Pairs** menu in the boundary part of the context menu for most physics interfaces. The **Continuity** condition is only suitable for pairs where the boundaries match.

BOUNDARY SELECTION

The selection list in this section shows the boundaries for the selected pairs.

PAIR SELECTION

Select the pairs where you want to impose continuity across the pair boundaries. Select the pairs from the **Pairs** list (Ctrl-click to deselect).

Identity and Contact Pairs

Physics Interface Axial Symmetry Node

In axisymmetric components, boundaries on the symmetry axis are boundaries where only a condition for the axial symmetry exists. The COMSOL Multiphysics software adds a default **Axial Symmetry** node that is active on all boundaries on the symmetry axis. The condition on the symmetry axis is typically a zero Neumann or no-flux condition.

BOUNDARY SELECTION

The selection list for boundaries is not available because this is a default boundary condition. In the list, boundaries that are not on the symmetry axis have (**not applicable**) added after the boundary number.

Physics Feature Nodes by Space Dimension

Constraint Reaction Terms

Enforcing a constraint condition is more or less a matter of finding a corresponding flux condition that leads to the desired values of the dependent variables. The hidden flux conditions introduced this way appear as *reaction terms* in the system of equations modeling the physics. These reaction terms normally have a physical meaning and correspond to a flux condition, for example:

- The reaction term enforcing a **Prescribed Displacement** on a solid model is a *reaction force*, similar to a **Boundary Load** boundary condition.
- The reaction term enforcing a **Pressure** in an acoustics model is a **Normal Acceleration**.
- The reaction term enforcing a **Temperature** in a heat transfer model is a **Heat Flux**.

Weak Constraints

The reaction terms in the model equations can be scaled in different ways, affecting mainly the numerics and solvers. In a model with more than one dependent variable, it is also possible to distribute the reaction fluxes, or forces, over the variables in different ways — while still enforcing the original constraint.

SYMMETRIC REACTION TERMS

Most boundary conditions of constraint type, by default, introduce reaction terms in such a way that an otherwise symmetric system of equations remains symmetric. This makes constraints *bidirectional* in the sense that all dependent variables that appear in a constraint expression are also affected by the reaction terms.

To illustrate this, suppose a **Prescribed Displacement** boundary condition is applied on a solid model, specifying that the x -displacement of the boundary, u , is proportional to the y -displacement, v , with a constant of proportionality, k , which is a function of the boundary temperature T :

$$u = k(T)v \quad (3-1)$$

If fully symmetric reaction terms are used to enforce this constraint, reaction forces are applied on both displacement components u and v , as well as a reaction heat flux in the heat transfer equation. Applying symmetric reaction terms this way, on completely different equations, is usually not meaningful.

In particular, the solid displacement equation and the heat transfer equation have different units. Because you can choose length and temperature unit independently, the relative scale of the equations is undefined and the symmetry of the coupled system irrelevant. Further you would not, from a physical point of view, expect a constraint on the displacement of a solid boundary to directly affect the temperature field in a model.

Symmetric and Nonsymmetric Constraints

RESTRICTED AND NONSYMMETRIC REACTION TERMS

As an alternative to the default (symmetric) application of reaction terms, you can choose to have these affect only the equations and variables in the physics interface where the constraint boundary condition is added. For the example in [Equation 3-1](#), the reaction terms can be restricted to act on the displacement variables and equations in the Solid Mechanics interface, leaving the temperature unaffected. Many different restrictions of this type are possible, in principle, and the COMSOL Multiphysics software generally provides two alternatives:

- The most consistent and general way to avoid spurious reaction terms affecting other physics is to start from the globally symmetric formulation and remove the terms entering equations belonging to other physics interfaces. This limits the reaction terms to affecting the current physics as if there were no other physics in the model, so the reaction terms preserve the symmetry. For [Equation 3-1](#), this means that reaction terms are distributed over both u and v equations, in proportions $1:k(T)$.
- The other alternative is to apply the reaction terms only on certain individual variables. Another way to look at [Equation 3-1](#) is to read it as prescribing a value for the x -displacement u , rather than prescribing a given relation between u and v . Accepting that view, it is reasonable to insert reaction terms only acting on u . Such reaction terms, in general, do not preserve symmetry even for a single physics interface.

Constraint Settings

Most constraint nodes include a **Constraint Settings** section, which is only available when **Advanced Physics Options** is selected from the **Show** menu (). This section provides settings controlling how reaction terms are applied and whether standard or weak constraints are used. Choose to **Apply reaction terms on**:

- **All physics (symmetric)** to apply reaction terms symmetrically on all dependent variables taking part in the constraint.
- **Current physics (internally symmetric)** to apply reaction terms symmetrically only on the dependent variables in the physics where the constraint is added. This leaves other physics unaffected by the constraint.
- **Individual dependent variables** to apply reaction terms only on selected variables. For most physics, this makes the constraint *unidirectional* and often nonsymmetric.

Select the **Use weak constraints** check box to replace the pointwise standard constraints with weak constraints (see [Weak Constraints](#) below). Note that this option introduces additional equations and dependent variables. If you

use pointwise constraints (the default; the **Use weak constraints** check box is cleared), then select a **Constraint method** for the pointwise constraints: **Elemental** or **Nodal**:

- Choose **Elemental** (the default) to make the software assemble the constraint on each node in each element; that is, there are usually several constraints at the same global coordinates because elements in the computational mesh overlap at nodes.
- Choose **Nodal** to make the software assemble a single constraint for each global node point. The nodal constraint method provides an averaging of the constraints from adjacent elements, which can be beneficial when the constraint has discontinuities between mesh elements (for example, due to discontinuities of the boundary normal). Another case where nodal constraints can be useful is in boundary conditions involving a coupling operator (such as continuity or periodic conditions). With elemental constraints, locking effects can sometimes occur because the coupling operator might map to slightly different points in the source boundary when it is applied to the same node point in different mesh elements.

Not all constraints provide all the above options. Some reaction term methods can be missing and weak constraints are not allowed. Some constraint nodes can also implement additional options.

Excluded Surfaces, Excluded Edges, and Excluded Points

Some constraint nodes, especially for structural modeling, include (depending on the space dimension and the geometry level of the constraint node) **Exclude Surfaces**, **Exclude Edges**, and **Exclude Points** sections, which are only available when **Advanced Physics Options** is selected from the **Show** menu (). You can use the settings in these sections to exclude some lower-level entities from being constrained for a certain boundary condition or constraint on the domain level. Conflicting Dirichlet conditions, such as constraints, can cause problems for several reasons:

- If constitutive properties differ a lot between two adjacent domains, the flux will be sensitive to whether a Dirichlet condition on a boundary includes the common edge or not.
- When you want to mix weak and pointwise constraints on the same degree of freedom, they cannot coexist on nodes shared at, for example, a corner.

The **Exclude Surfaces**, **Exclude Edges**, and **Exclude Points** sections contain settings for selecting surfaces (that is, boundaries in 3D), edges (that is, boundaries in 2D and edges in 3D), and points, respectively. See [About Selecting Geometric Entities](#) for information about selecting geometric entities such as edges.

Weak Constraints

The standard method to enforce constraints in the COMSOL Multiphysics software applies the constraints pointwise at node points in the mesh. At each node point, only local values of the dependent variables are affected by the constraint, making the constraints independent of each other. The solvers can therefore eliminate both the constrained degrees of freedom and the constraint force terms, effectively reducing the system of equations and decreasing the number of degrees of freedom being solved for.

Weak constraints enforce the constraint in a local average sense, using shape functions as weights. Reaction terms are explicitly included in the system of equations, which is extended with *Lagrange multiplier* variables. These Lagrange multipliers in general have a physical meaning and an interpretation as a constraint force or flux. Whereas a standard constraint decreases the number of degrees of freedom by the number of unique constraints, weak constraints increase the degrees of freedom by the same number.

A weak constraint is respected only on average over each Lagrange multiplier shape function, rather than pointwise at mesh nodes. When it is possible to satisfy the constraint everywhere on each mesh element, standard and weak constraints in general lead to the same solution. Conversely, when constraints are contradictory or impossible to

satisfy everywhere, standard and weak constraints can distribute the error differently, and therefore lead to slightly different solutions.

Weak constraints can be of use in the following situations:

- Standard constraints must never contain time derivatives of the dependent variables. Weak constraints do not have this limitation because they allow the same variables as any other term in the combined system of equations. Note that reaction terms cannot be applied symmetrically to time derivatives but must be selectively applied to individual variables.
- When the reaction force or flux is needed during a solution, because it enters into a coefficient somewhere, the Lagrange multiplier from a weak constraint can provide an accurate value (see [Computing Accurate Fluxes](#)). The corresponding variables computed from derivatives of the dependent variables are not as accurate and can, if used, introduce considerable errors in the solution.
- When constraints are strongly nonlinear, weak constraints can allow faster and more robust convergence. For nonlinear constraints, the true linearized subproblem solved in each solution step depends on the value of the Lagrange multiplier variables from the previous step. When using standard constraints, this information is discarded between solution steps. Using weak constraints, the Lagrange multiplier values are instead retained between steps because they are part of the solution vector.

Compared to standard, eliminated, constraints, weak constraints can also have the following drawbacks:

- Discontinuous constraints result in (theoretically) infinite Lagrange multipliers. In practice, large oscillations result.
- Pointwise and weak constraints on the same set of variables on adjacent boundaries (that is, boundaries that share common node points in the mesh) do not work. This means that if all boundaries must be constrained on a solid and you want to use a weak constraint on one boundary segment (one face), the weak constraint must be used on the entire boundary of the solid (if the boundary is connected).
- Lagrange multipliers are in some cases difficult to interpret. For example, Lagrange multipliers from Dirichlet conditions in axial symmetry are not equal to the reaction flux per area but rather per length and full revolution. For separate Weak Constraints nodes in axial symmetry, the default quadrature settings include a multiplication by $2\pi r$, making the Lagrange multiplier represent flux per area.
- Because extra unknowns are introduced for the Lagrange multipliers, the size of the problem increases compared to the standard constraint elimination method.
- The Lagrange multiplier variables added by the weak constraints have a different unit than the main system variables and can therefore be of a different order of magnitude. This can lead to scaling problems. Usually the automatic variable scaling in the solvers is sufficient, but there are cases when manual scaling is needed.
- Weak constraints introduce zeros on the main diagonal of the Jacobian matrix of the discretized system, which therefore cannot be positive definite. This makes certain linear solvers and preconditioners unavailable for solving problems with weak constraints. In particular, the conjugate gradients iterative solver does not work, and neither does the SOR class of preconditioners and smoothers. Instead, try another iterative solver and use the Vanka algorithm with the Lagrange multipliers as the Vanka variables, or use the incomplete LU factorization algorithm as preconditioner.

Periodic Boundary Conditions

Use *periodic boundary conditions* to make the solution equal on two different (but usually equally shaped) boundaries.

To add a periodic boundary condition, in the **Model Builder**, right-click a physics interface node and select **Periodic Condition**. The periodic boundary condition typically implements standard periodicity so that $u(x_0) = u(x_1)$ (that is, the value of the solution is the same on the periodic boundaries). In most cases you can also choose antiperiodicity so that the solutions have opposing signs: $u(x_0) = -u(x_1)$. Other options such as Floquet periodicity or cyclic symmetry may be available. The periodicity is implemented in such a way that fluxes become periodic in the same way as the solution itself.

For fluid flow physics interfaces, the **Periodic Flow Condition** provides a similar periodic boundary condition but without a selection of periodicity. Instead, it allows specifying a pressure difference between the source and destination boundaries.

Typically, the periodic boundary conditions determine the source and destination boundaries automatically, but you can also add **Destination Selection** subnode to manually split the periodic boundary condition's selection into source and destination selections.

The KdV Equation and Solitons: Application Library path
COMSOL_Multiphysics/Equation_Based/kdv_equation.

ORIENTATION OF SOURCE AND DESTINATION

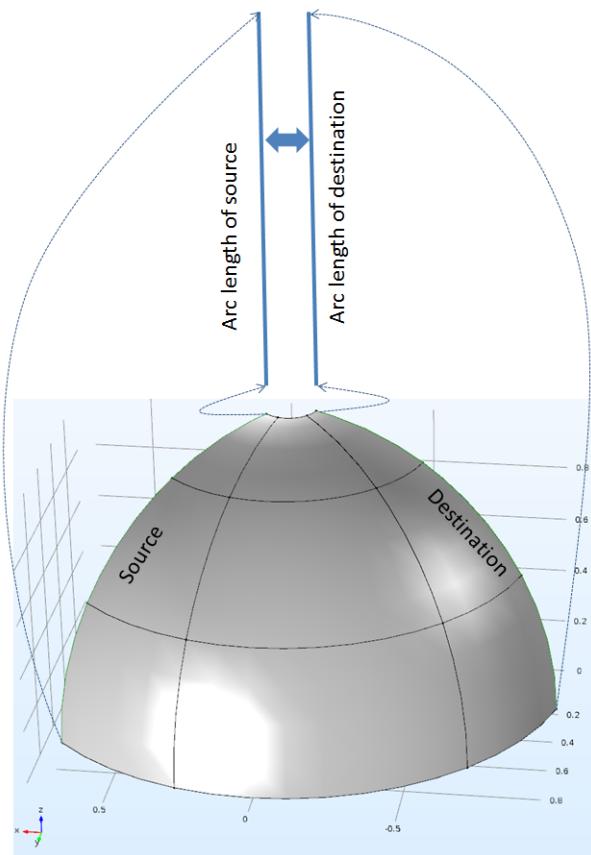

The periodic condition applies a constraint on the destination selection, constraining the solution at each destination point \mathbf{r}_{dst} to be equal to the solution at a corresponding source point \mathbf{r}_{src} . When the periodic condition is applied on surfaces in 3D or edges in 2D, the source point is computed using a rotation of the position relative to the destination and source centers of mass, $\mathbf{r}_{0,\text{dst}}$ and $\mathbf{r}_{0,\text{src}}$:

$$\mathbf{r}_{\text{src}} = \mathbf{r}_{0,\text{src}} + R(\mathbf{r}_{\text{dst}} - \mathbf{r}_{0,\text{src}}) \quad (3-2)$$

where R is a rotation matrix encoding the relative orientation of the source and destination boundaries. It is normally determined automatically from the cross product of the source and destination boundary normal directions. That is, the rotation is performed about an axis perpendicular to the plane spanned by the normal directions, which are evaluated at arbitrary points on each boundary.

When the periodic condition is applied on a shell or beam in 3D, the selection is edges or vertices without a well-defined normal. An automatic mapping from destination point to source point is defined based on the

geometry parametrization. Each destination point is mapped on a source point with the same arc length parameter value (see the image below).

The automatically computed relative orientation is in most cases the one expected. In particular, it is correct if the source and destination have unique normal vectors which are parallel but pointing in opposite directions, unless the geometry is twisted about that direction. But there are a number of situations when the automatic orientation is not necessarily the one expected:

- The geometry is twisted in such a way that the destination selection cannot be represented as a rotation of the source about a single axis.
- The source and destination boundaries are not planar, such that their normals are not unique.
- The source and destination selections are edges or points in 3D, and the arc length parameter values are growing in opposite directions.

For most periodic boundary conditions in the physics interfaces, it is then possible to specify the relative orientation of the source and destination selections using coordinate systems.

The orientation settings appear in an **Orientation of Source** section in the main periodic condition node and in an **Orientation of Destination** section in a **Destination Selection** subnode. To display these settings, first select **Advanced Physics Options** from the **Show** menu () at the top of the **Model Builder** window. The **Orientation of Destination** section is only visible if the source orientation has been chosen manually.

In both sections, there is a **Transform to intermediate map** list. In the **Orientation of Source** section in the main periodic condition node, its default value is **Automatic**. Other possible values represent coordinate systems, including all coordinate system nodes defined in the component as well as the canonical **Global coordinate system**. The latter is the default choice for the **Orientation of Destination** section in **Destination Selection** subnodes.

The chosen source and destination coordinate systems define transformation matrices, T_{src} and T_{dst} , whose row index refers to local coordinate system components, while the column index refers to global coordinates on the source and destination selections, respectively. A rotation matrix as defined by [Equation 3-2](#) is computed by assuming that the source and destination coordinate system coordinates refer to the same basis:

$$R = T_{\text{src}}^T T_{\text{dst}}^{-T}$$

Computing Accurate Fluxes

Flux Computation Methods

The COMSOL Multiphysics software provides three ways to compute accurate fluxes and reaction forces:

- The first approach involves the reaction force operator (`reacf`) that makes it possible to compute integrals of reaction forces or fluxes during analysis. See `reacf` for details.
- The second, more general approach for calculating reaction forces and fluxes is to use weak constraints. Use this approach when you need reaction forces or fluxes in other contexts than calculating integrals of reaction forces or fluxes.

Weak Constraints

- Some physics interfaces provide a third way of computing accurate fluxes. Under the **Discretization** section (if **Advanced Physics Options** is active on the **Show** menu), select the **Compute boundary fluxes** check box. The solver then computes variables storing an accurate boundary flux from each boundary into the adjacent domain (in addition to the standard extrapolated value). On interior boundaries, there are two flux variables corresponding to the flux into the domains on either side of the boundary. Unlike the other methods, these variables are available also on unconstrained boundaries. This method is active by default in Coefficient Form PDE, General Form PDE, heat transfer, and mass transport interfaces. There is also an **Apply smoothing to boundary fluxes** check box that is selected by default. The smoothing can provide a more well-behaved flux value close to singularities. See also [Boundary Flux Operators: uflux and dflux](#).

When using weak constraints in interfaces, the Lagrange multipliers are additional dependent variables in those physics interfaces. When using the reaction force operator, the reaction force operator of a certain dependent variable corresponds to the Lagrange multiplier of that dependent variable. The Lagrange multipliers correspond to the following quantities in the physics interfaces:

TABLE 3-6: INTERPRETATION OF LAGRANGE MULTIPLIERS

PHYSICS INTERFACE	QUANTITY
Electrostatics	Surface charge density
Magnetic Fields	Surface current
Electric Currents	Current density
Heat Transfer	Heat flux
Transport of Diluted Species	Flux
Solid Mechanics	Force per area
Pressure Acoustics	Normal displacement (acceleration for eigenfrequency studies)
Laminar Flow	Total force per area

The sign of the Lagrange multiplier is the same as the one used when applying the corresponding quantity explicitly in a flux condition. As a general rule, the sign corresponds to an action by the surroundings on the model, rather than the opposite.

The program computes only the part of the boundary flux captured by the Lagrange multiplier. You might have additional flux coming from boundary sources or nonidentity constraint matrices. This should not happen in the physics interfaces, though.

Lagrange multipliers in axial symmetry are not equal to the reaction flux per area but rather per length and full revolution.

Flux Calculation Example — Heat Transfer Model

The reaction forces are computed from the value of the residual vector at every node point where a constraint is applied. Therefore, the reaction forces should be thought of as discrete values at each node point rather than continuous fields.

The boundary flux variables are computed in a similar way to the reaction forces but with two important differences:

- First, on each boundary, the contributions to the residual vector from the boundary and from the adjacent domains are computed separately. This makes it possible to compute the flux into each adjacent domain even when there is no constraint on the boundary so that the full residual vector is zero.
- Second, the nodal fluxes computed from the residual vector are further processed and represented as a continuous field on the boundary. The integral of this flux field over a boundary is equal to the sum of the nodal fluxes.

Flux Calculation Example — Heat Transfer Model

Consider a heat transfer model where a heat flux of 1 W/m^2 flows in through one boundary of a square 2D region. All other boundaries are kept at a fixed temperature of 293.15 K. The material is copper. This example verifies that the flux is conserved exactly using a Lagrange multiplier for computing the total flux over the boundaries with a fixed temperature.

MODEL WIZARD

- 1 Open the Model Wizard (see [Open a New Window to Begin Modeling](#)).
- 2 On the **Select Space Dimension** page, click the **2D** button .
- 3 In the list of physics interfaces, under **Heat Transfer** click **Heat Transfer in Solids** . Click **Add**.
- 4 Click the **Study** button . On the **Select Study** page under **Preset Studies**, click **Stationary** .
- 5 Click **Done**.

GEOMETRY

In the **Geometry** toolbar, from the **Rectangle** menu, click to add a **Square** (1-by-1 m).

MATERIALS

- 1 In the **Material** toolbar, click **Browse Materials** .
- 2 Under **Built-in**, click **Copper** then click **Add to Component**.
- 3 Click **Done** .

HEAT TRANSFER

The **Heat Transfer in Solids** node defines the material properties to be those from the material (copper) and does not need to be changed, but the default boundary condition is thermal insulation. Instead, add a heat flux to the bottom boundary and a fixed temperature on the other three boundaries.

- 1 In the **Model Builder**, click the **Heat Transfer in Solids** node .
- 2 In the **Physics** toolbar, from the **Boundaries** menu click **Heat Flux** .
- 3 In the **Graphics** window, click boundary 2 (the bottom boundary) to add it to the selection.
- 4 In the **Settings** window for **Heat Flux**, enter 1 (1 W/m²) in the **General inward heat flux** field for q_0 .
- 5 Right-click **Heat Transfer in Solids** node  and select **Temperature** .
- 6 In the **Graphics** window, select the other three boundaries (1, 3, and 4) and add them to the selection for the temperature condition.
- 7 This step is only needed to show how to use a Lagrange multiplier for an accurate flux. Built-in variables for accurate fluxes are available directly also without this step.

To display the weak constraint option to add the Lagrange multipliers, click the **Show** button () and select **Advanced Physics Options**. In the **Model Builder** click the **Temperature** node. In the **Settings** window, keep the default value for the temperature, 293.15 K. Click to expand the **Constraint Settings** section and select the **Use weak constraints** check box. This adds a Lagrange multiplier for the heat flux as an extra variable to compute.

COMPUTING THE SOLUTION

In the **Home** toolbar, click **Compute** . The resulting plot shows the temperature distribution in the domain.

RESULTS — FLUX EXPRESSION AND LAGRANGE MULTIPLIER

- 1 Under **Results>Derived Values>Integration**, click **Line Integration** .
- 2 Select the three boundaries with a fixed temperature (1, 3, and 4) to add them to the selection in the **Settings** window for **Line Integration**.
- 3 Click the **Replace Expression** button () and select **Heat Transfer in Solids>Boundary fluxes>Normal total heat flux** (the variable `ht.ntflux`).
- 4 Click the **Evaluate** button ().

The total normal heat flux across these boundaries appears in the **Table** under **Normal total heat flux (W/m)** and is exactly equal to the influx of 1 W/m (the normal flux is by convention positive in the direction of the normal).

If you were to clear the **Compute boundary fluxes** check box in the **Discretization** section (click the **Show** button  and select **Advanced Physics Options** first) for the **Heat Transfer in Solids** node, and then re-solve the model, the same flux variable is not as accurate and has a value of about 0.986 W/m. That value approaches 1 if you refine the mesh.

- 5 Click the **Replace Expression** button () and select **Heat Transfer>Lagrange multiplier for temperature** (the variable `T_1m`).
- 6 Click the **Evaluate** button (.

The total heat flux across these boundaries appears in the **Table** under **Lagrange multiplier for temperature** and is -1, exactly equal to the influx (but with opposite sign) without the need for a computationally expensive extremely fine mesh. This method is useful for physics where built-in accurate flux variables are not available.

Using Load Cases

About Load Cases

For linear stationary problems it can be of interest to see the solution for several different loads F (right-hand side of the basic PDE) on the same structure (a model where the geometry and materials are defined and do not change). Typically this is used for studies using linear combinations of different loads — *load cases*. It is then possible to solve for these load cases in a computationally efficient way because there is no need to reassemble the stiffness matrix. Varying constraints can also be part of a general load case definition, and the COMSOL Multiphysics software supports load cases that are combination of loads, with optional weights, and constraints.

- [The Relationship Between Study Steps and Solver Configurations](#)
- [Physics Symbols](#)
- [Stationary study step](#)

Defining Load Groups and Constraint Groups

For boundary conditions that represent loads and constraints, as well as other loads and constraints such as body loads, you can define *load groups* and *constraint groups*, which contain the loads and constraints, respectively, that you want to use as parts of load cases. All loads and constraints for structural mechanics as well as boundary conditions such as heat flux (a load) and temperature (a constraint) in heat transfer support load groups and constraint groups. You can create load groups and constraint groups in two ways: from the **Global Definitions** node's context menu or a physics node's context menu. Both methods add the node under **Global Definitions**.

ADD A LOAD OR CONSTRAINT GROUP FROM THE GLOBAL DEFINITIONS CONTEXT MENU

Add a **Load Group** (grid icon) or **Constraint Group** (grid icon) under **Global Definitions** to create groups to which you can later assign loads and constraints. If you group the nodes, the load and constraint groups display under the **Load and Constraint Groups** node (grid icon). See [Figure 3-21](#).

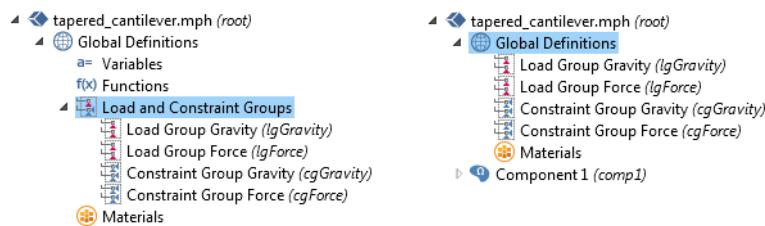

Figure 3-21: An example of the node grouping when **Group by Type** is selected (left) and when **Ungroup** is selected (right).

ADD A LOAD OR CONSTRAINT GROUP FROM A PHYSICS NODE CONTEXT MENU

Right-click a physics node for any load or constraint (for example, a Fixed Constraint, Heat Source, or Boundary Load node) and choose **Load Group>New Load Group** or **Constraint Group>New Constraint Group**, respectively. The software creates a Load Group or Constraint Group under Global Definitions and at the same time assigns that physics node (a load or a constraint) to that group.

ASSIGN A LOAD OR CONSTRAINT TO A GROUP

To assign a load or a constraint to a load group or constraint group, right-click the physics node for a load or constraint and from the **Load Group** or **Constraint Group** submenu choose one of the following (see Figure 3-22):

- **Active in All Load Groups** (or **Active in All Constraint Groups**). This is the default setting, which you can use for some boundary conditions or other parts of the physics design that take part in all load cases.
 - One of the defined load groups or constraint groups such as **Load Group 1**, **Load Group 2**, and so on.
 - **New Load Group** (or **New Constraint Group**) to create a new group as described earlier in this section.

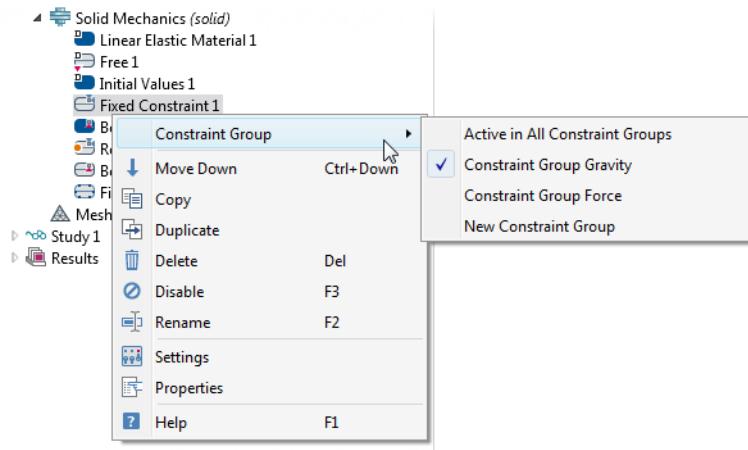

Figure 3-22: An example of the context menu options when a load or constraint physics node is right-clicked, in this case, the Fixed Constraint node.

Define as many groups as you need for the load cases that you want to study. Each load or constraint can only belong to one group. The next step is then to define the actual load cases as combinations of these groups (see [Defining and Evaluating Load Cases](#)).

When the Load Group or Constraint Group is applied to a node under a physics interface, the node indicates this visually. For example, the **Fixed Constraint** and **Roller** nodes have the blue **Constraint Group** symbol in the upper-right corner.

corner and the **Body Load** and **Boundary Load** nodes have the red **Load Group** symbol in the upper-right corner as in Figure 3-23.

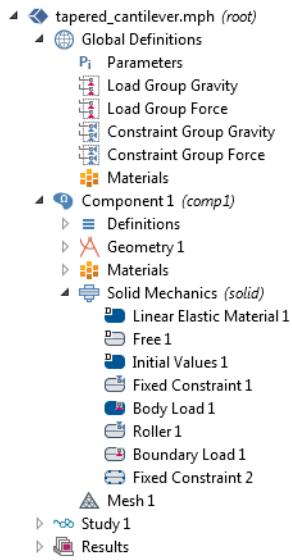

Figure 3-23: An example of the Load and Constraint Groups defined under Global Definitions with loads and constraints applied to nodes under Solid Mechanics.

- *Tapered Cantilever with Two Load Cases:* Application Library path **COMSOL_Multiphysics/Structural_Mechanics/tapered_cantilever**
- If you have the Structural Mechanics Module, also see *Pratt Truss Bridge:* Application Library path **Structural_Mechanics_Module/Civil_Engineering/pratt_truss_bridge**.

Load Group

Add a **Load Group** () under the **Global Definitions** node to create a load group to which you can assign one or more loads. You can then activate the load group in one or more *load cases* for efficiently solving a structural mechanics or heat transfer model to analyze the effects of various loads or sources.

SETTINGS

The **Label** is the default coordinate system name. The default **Parameter name** (for the first coordinate system in the model) is **lg**. This can be modified if you want to use a more descriptive parameter name (for example, **lgGravity**). You can also create load groups from physics nodes for structural mechanics that represent loads and support load cases: Right-click the physics node and choose **Load Group>New Load Group**.

Constraint Group

Add a **Constraint Group** () under the **Global Definitions** node to create a constraint group to which you can assign one or more constraints. You can then activate the constraint group in one or more *load cases* for efficiently solving a model to analyze the effects of various constraints.

SETTINGS

The **Label** is the default coordinate system name. The default **Parameter name** (for the first coordinate system in the model) is **cg**. This can be modified if you want to use a more descriptive parameter name (for example, **cgForce**).

You can also create constraint groups from physics nodes for structural mechanics that represent constraints and support load cases: Right-click the physics node and choose **Constraint Group>New Constraint Group**.

If you select **Group by Type** from the context menu, either right-click the **Global Definitions** node or the **Loads and Constraints Groups** node () to add a **Load Group** or **Constraint Group**.

Defining and Evaluating Load Cases

You define load cases in the **Settings** window for the **Stationary** study. Follow these steps to create load cases:

- 1 In the **Model Builder** under **Study**, in the **Settings** window for **Stationary** () , click to expand the **Study Extensions** section.
- 2 Select the **Define load cases** check box (see [Figure 3-24](#)).
- 3 In the **Define load cases** area, click the **Add** (+) button underneath the table to add a load case.
- 4 The added load case appears last in the table of load cases. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** (≡) buttons to rearrange the load cases in the table, and click the **Add** (+) button to add more load cases.
- 5 For each load case, you can change its name from the default (Load case 2, for example) in the **Load case** column.
- 6 Include the load groups and constraint groups for each load case by clicking the in the columns for the groups to include. The symbol changes to in order to indicate that the group participates in the load case.
- 7 For load groups, optionally change the weight from its default value of 1.0 in the corresponding **Weight** column (the **Weight** column to the right of the load group that it affects). Use a positive value other than 1 to increase or decrease the magnitude of the load; a negative value also reverses the load's direction.

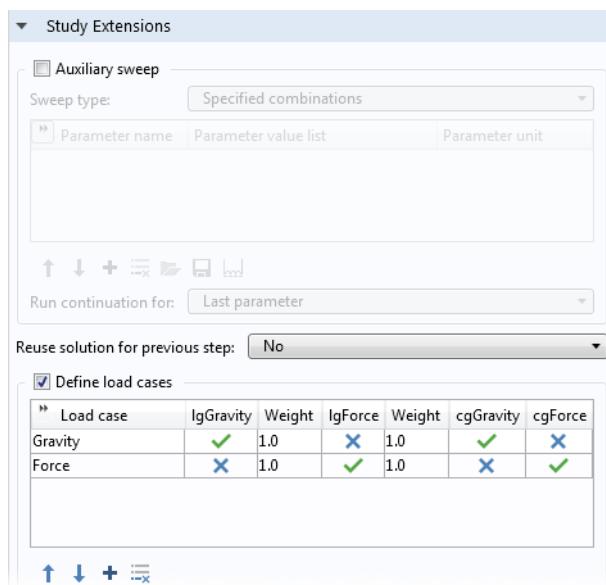

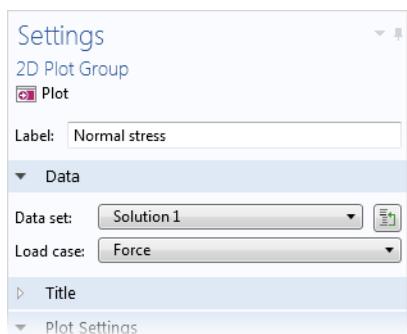

Figure 3-24: An example of the Stationary node's Study Extensions section. Click in the table of load cases to select or remove loads and constraints from the load case.

When you have defined all load cases, you can compute the solution. The COMSOL Multiphysics software then solves for all load cases directly. In the plot groups that are created, a **Load case** list in the **Data** section of the **Settings** window for **Plot Group** contains all load cases. To plot using the solution for a specific load case, select the load case of interest from the **Load case** list, and then click **Plot** ().

Numerical Stabilization

About Numerical Stabilization in COMSOL

This section discusses the numerical stability of the generic scalar convection-diffusion transport equation

$$\frac{\partial u}{\partial t} + \beta \cdot \nabla u = \nabla \cdot (c \nabla u) + F \quad (3-3)$$

where β is the convective velocity vector, c is the diffusion coefficient, u is a transported scalar, and F is a source term. The underlying finite element discretization method in COMSOL Multiphysics is the Galerkin method.

When discretizing [Equation 3-3](#) using the Galerkin method, the resulting numerical problem becomes unstable for an element Péclet number (Pe) larger than one ([Ref. 1](#)):

$$Pe = \frac{\|\beta\| h}{2c} > 1 \quad (3-4)$$

where h is the mesh element size. The Péclet number is a measure of the relative importance of the convective effects compared to the diffusive effects; a large Péclet number indicates that the convective effects dominate over the diffusive effects.

Oscillations can occur where any of the following conditions exist and the Péclet number exceeds one:

- A Dirichlet boundary condition can lead to a solution containing a steep gradient near the boundary, forming a boundary layer. If the mesh cannot resolve the boundary layer, this creates a local disturbance.
- A space-dependent initial condition that the mesh does not resolve can cause a local initial disturbance that propagates through the computational domain.
- A small initial diffusion term close to a nonconstant source term or a nonconstant Dirichlet boundary condition can result in a local disturbance.

As long as diffusion is present, there is — at least in theory — a mesh resolution beyond which the discretization is stable. This means that the spurious oscillations can be removed by refining the mesh. In practice, this method is seldom feasible because it can require a very dense mesh. Instead, it is common practice to use stabilization methods — that is, methods that add artificial diffusion. The COMSOL products include several such methods, some of which are described in [An Example of Stabilization](#).

Consistent Stabilization and Inconsistent Stabilization Sections on Settings Windows

Numerical stabilization is available for physics interfaces that model transport such as fluid flow or convective heat transfer, where the fundamental governing equations are less stable than, for example, conduction-dominated models, solid mechanics models, and wave propagation in the frequency domain.

Several physics interfaces have these settings available, and below you find the common information about the stabilization settings. Differences not described below are noted for the individual interface documentation.

CONSISTENT STABILIZATION

To enable this section, click the **Show** button () and select **Stabilization**.

There are two *consistent stabilization methods*: **Streamline diffusion** and **Crosswind diffusion**. Usually, both check boxes for these methods are selected by default and should remain selected for optimal performance. Consistent stabilization methods do not perturb the original transport equation.

Crosswind Diffusion and Lower Gradient Limit

In some cases, if the **Crosswind diffusion** check box is selected, the **Lower gradient limit** g_{lim} (SI unit: K/m) field is available. This variable corresponds to the smallest concentration change across an element considered by the stabilization, and is used to make sure that the crosswind diffusion expressions are valid also in regions with small to negligible concentration changes.

Residual

In some cases, and for both consistent stabilization methods, select a **Residual** (or **Equation Residual**). **Approximate residual** is the default setting and it means that derivatives of the diffusion tensor components are neglected. This setting is usually accurate enough and is faster to compute. If required, select **Full residual** instead.

INCONSISTENT STABILIZATION

To enable this section, click the **Show** button () and select **Stabilization**.

There is usually just one *inconsistent stabilization method* — **Isotropic diffusion**. This method is equivalent to adding a term to the diffusion coefficient in order to dampen the effect of oscillations by making the system somewhat less dominated by convection. If possible, minimize the use of the inconsistent stabilization method because by using it you no longer solve the original problem. By default, the **Isotropic diffusion** check box is not selected because this type of stabilization adds artificial diffusion and affects the accuracy of the original problem. However, this option can be used to get a good initial guess for underresolved problems.

If required, select the **Isotropic diffusion** check box and enter a **Tuning parameter** δ_{id} as a scalar positive value. The default value is 0.25 (a reasonable value to start with is roughly 0.5 divided by the element order). A higher value adds more isotropic diffusion.

- [An Example of Stabilization](#)
- [Stabilization Techniques](#)

An Example of Stabilization

This example uses the Heat Transfer interface. To illustrate the concepts, consider the problem

$$\cos\left(\frac{\pi}{3}\right)\frac{\partial u}{\partial x} + \sin\left(\frac{\pi}{3}\right)\frac{\partial u}{\partial y} = 10^{-4}\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) + 1 \quad (3-5)$$

solved on the unit square. [Equation 3-5](#) is discretized using 10 times 10 quadratic Lagrangian elements. The boundary conditions are:

- $u = 1$ for $x = 0$
- $u = 1$ for $y = 0$
- $u = 0$ for $x = 1$
- $u = 0$ for $y = 1$

[Figure 3-25](#) shows the mesh and boundary conditions. In general, using uniform meshes for transport problems is not recommended. Nevertheless, this example uses a uniform mesh to demonstrate the different stabilization techniques.

The expected solution rises slowly and smoothly from the left and lower boundaries and has sharp boundary layers along the upper and right boundaries. [Figure 3-26](#) shows a reference solution obtained using 100-by-100 quadratic Lagrangian elements with streamline diffusion and crosswind diffusion (see the next section). The arrows indicate the direction of β .

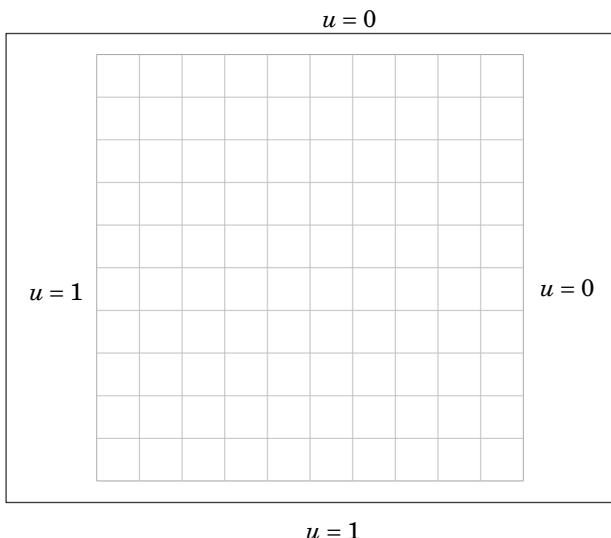

Figure 3-25: The computation domain, mesh, and boundary condition for Equation 3-5.

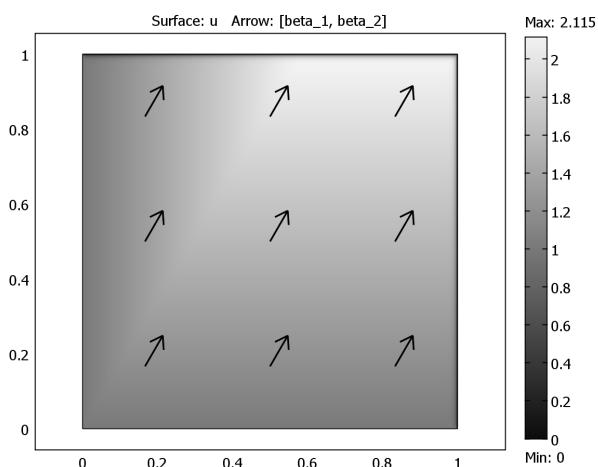

Figure 3-26: Reference solution of Equation 3-5. Solved using 100 times 100 quadratic elements with streamline diffusion and crosswind diffusion.

The cell Péclet number for this example is

$$\text{Pe} = \frac{1 \cdot 0.1}{2 \cdot 10^{-4}} = 500 \gg 1$$

Figure 3-27 displays the solution obtained using the mesh in Figure 3-25 and (unstabilized) Galerkin discretization. As can be expected with such a high Péclet number, the unstabilized solution shows little, if any, resemblance to the reference solution in Figure 3-26. The right plot in Figure 3-27 shows a cross-sectional plot along the dashed line, $y = 0.8$ and the corresponding reference solution. Notice that the unstabilized solution is destroyed by oscillations.

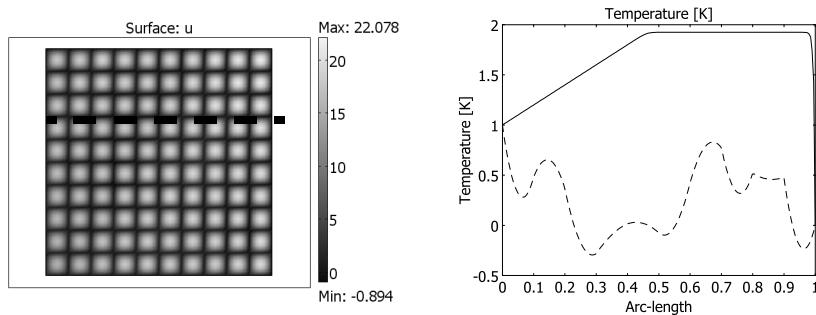

Figure 3-27: Equation 3-5 solved using unstabilized Galerkin formulation. The right plot compares the unstabilized solution (dashed line) along the dashed line in the left plot ($y = 0.8$) with the reference solution (solid line).

The [Stabilization Techniques](#) section explores how different stabilization techniques affect the solution of this example.

Stabilization Techniques

Several techniques for handling numerical instabilities without the need for mesh refinement are available. They all have in common that they add terms to the transport equation. These terms introduce numerical diffusion (artificial diffusion, artificial viscosity, or numerical viscosity are other common names) that stabilize the solution. To display these sections, click the **Show** button (🔍) and select **Stabilization**.

- Heat Transfer Consistent and Inconsistent Stabilization Methods
- Numerical Stability — Stabilization Techniques for Fluid Flow

CONSISTENT STABILIZATION

A consistent stabilization method adds numerical diffusion in such a way that if u is an exact solution to [Equation 3-3](#), then it is also a solution to the problem with numerical diffusion. In other words, a consistent stabilization method gives less numerical diffusion the closer the numerical solution comes to the exact solution.

INCONSISTENT STABILIZATION

An inconsistent stabilization method adds numerical diffusion in such a way that if u is an exact solution to [Equation 3-3](#), then it is not necessarily a solution to the problem with numerical diffusion. In other words, an inconsistent method adds a certain amount of diffusion independently of how close the numerical solution is to the exact solution.

ISOTROPIC DIFFUSION

Adding isotropic diffusion is equivalent to adding a term,

$$c_{\text{art}} = \delta_{\text{id}} h \|\beta\|$$

to the physical diffusion coefficient, c . Here δ_{id} is a tuning parameter. This means that you do not solve the original problem, [Equation 3-3](#), but rather the modified $O(h)$ -perturbed problem

$$\frac{\partial u}{\partial t} + \beta \cdot \nabla u = \nabla \cdot ((c + c_{\text{art}}) \nabla u) + F \quad (3-6)$$

Hence, isotropic diffusion is an inconsistent stabilization method. If $\delta_{\text{id}} = 0.5$, the new cell Péclet number can be expressed as

$$Pe = \frac{h\|\beta\|}{2(c + c_{\text{art}})} = \frac{h\|\beta\|}{2c + h\|\beta\|}$$

Clearly, as $\|\beta\|$ approaches infinity, Pe approaches, but never exceeds, one. While a solution obtained with isotropic diffusion might not be satisfactory in all cases, the added diffusion definitely dampens the effects of oscillations and impedes their propagation to other parts of the system. It is not always necessary to set δ_{id} as high as 0.5 to get a smooth solution, and its value should be smaller if possible. A good rule of thumb is to select $\delta = 0.5/p$, where p is the order of the basis functions. The default value is $\delta_{\text{id}} = 0.25$.

[Figure 3-28](#) shows the effect of isotropic diffusion on [Equation 3-5](#) with $\delta_{\text{id}} = 0.25$. Although the solution is smooth, the comparison with the reference solution in the right plot reveals that the isotropic diffusion introduces far too much diffusion.

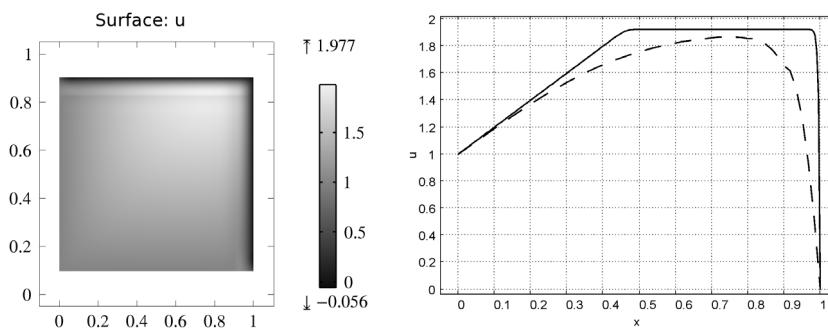

Figure 3-28: [Equation 3-5](#) solved using isotropic diffusion. The right plot compares the stabilized solution (dashed line) along $y = 0.8$ with the reference solution (solid line).

STREAMLINE DIFFUSION

The streamline diffusion method in the COMSOL Multiphysics software is a consistent stabilization method. When applied to [Equation 3-3](#), it recovers the streamline upwind Petrov-Galerkin (SUPG) method, but it can also recover functionality from the Galerkin least-squares (GLS) method. Both methods are described below. For theoretical details, see [Ref. 1](#) and [Ref. 2](#).

Streamline Upwind Petrov-Galerkin (SUPG)

The theory underlying SUPG is a bit too complicated to describe here, but the resulting expressions can be shown to be closely related to upwinding schemes in finite difference and finite volume methods. SUPG can be shown to add a smaller amount of stability than isotropic diffusion (see [Ref. 3](#)), but while the accuracy of isotropic diffusion is at best $O(h)$, the accuracy of SUPG can be shown to be at least $O(h^{p+1/2})$ where $p \geq 1$ is the order of the basis functions.

[Figure 3-29](#) displays the effect of SUPG on the solution of [Equation 3-5](#). The solution closely follows the reference solution away from the boundary layers, but at the boundary layers, oscillations occur. This is a typical behavior for streamline diffusion: the solution becomes smooth and exact in smooth regions but can contain local oscillations at sharp gradients.

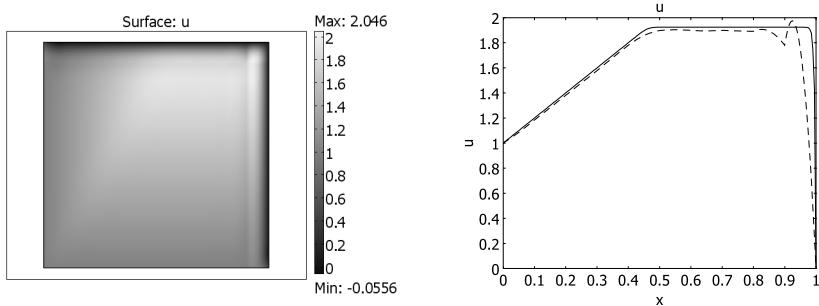

Figure 3-29: Equation 3-5 solved using streamline diffusion. The right plot compares the stabilized solution (dashed line) along $y = 0.8$ with the reference solution (solid line).

Galerkin Least-Squares (GLS)

Galerkin least-squares (GLS) is a more advanced version of SUPG, with which it shares many features. GLS, for example, is also a consistent method and has the same order of accuracy as SUPG. To understand the differences between GLS and SUPG, consider the following extended form of Equation 3-3:

$$\frac{\partial u}{\partial t} + \beta \cdot \nabla u = \nabla \cdot (c \nabla u) + su + F \quad (3-7)$$

where s is a production coefficient if $s > 0$ and an absorption coefficient if $s < 0$. If $s \neq 0$, the numerical solution of Equation 3-7 is characterized by the Péclet number (see Equation 3-4) and the element Damköhler number:

$$Da = \frac{|s| h}{\|\beta\|}$$

A new dimensionless number can be formed by combining the Damköhler number and the Péclet number:

$$2DaPe = \frac{|s| h^2}{c} \quad (3-8)$$

The (unstabilized) Galerkin discretization becomes unstable if $2DaPe > 1$ (Ref. 4), that is, if the production/absorption effects dominate over the viscous effects. GLS differs from SUPG in that GLS relaxes this requirement while SUPG does not.¹

CROSSWIND DIFFUSION

Streamline diffusion introduces artificial diffusion in the streamline direction. This is often enough to obtain a smooth numerical solution if the exact solution of Equation 3-3 (or Equation 3-7) does not contain any discontinuities. At sharp gradients, however, undershoots and overshoots can occur in the numerical solutions (see Figure 3-29). Crosswind diffusion addresses these spurious oscillations by adding diffusion orthogonal to the streamline direction — that is, in the crosswind direction.

Crosswind diffusion methods are consistent, but they are also nonlinear. This means that the discrete equation system becomes nonlinear even if the original equation (Equation 3-3 or Equation 3-7) is linear, which can increase the computational cost.

Use crosswind diffusion if it is important to avoid undershoots or overshoots. Typical examples are concentrations that must not become negative and mass fractions that must be between zero and one.

1. The streamline diffusion stabilization in COMSOL Multiphysics is GLS but without any viscous terms in the test operator in the stabilization term.

The crosswind diffusion option adds a weak contribution as suggested in Ref. 5. For the scalar example here, the term reads

$$-\nu^h \frac{\partial c}{\partial x_i} g^{ij} \frac{\partial c}{\partial x_j}$$

where g^{ij} is the covariant metric tensor. The coefficient ν^h is for Navier-Stokes systems a modified version of the Hughes-Mallet (HM) formulation of Ref. 6. In the scalar case, the modified HM formulation reduces effectively to the form suggested in Ref. 6. Additionally, Ref. 7 suggests to reduce ν^h for higher-order elements. The formulation in the COMSOL Multiphysics software multiplies ν^h with a factor

$$(\sqrt{2})^{1-N}$$

where N is the shape function order.

Figure 3-30 shows the example problem (Equation 3-5) solved using streamline diffusion and crosswind diffusion. Oscillations at the boundary layers are almost completely removed (compare with Figure 3-29), but it has been achieved by the introduction of some extra diffusion. In general, crosswind diffusion tries to smear out the boundary layer so that it becomes just wide enough to be resolved on the mesh (Figure 3-25). To obtain a sharper solution and remove the last oscillations, the mesh needs to be refined locally at the boundary layers.

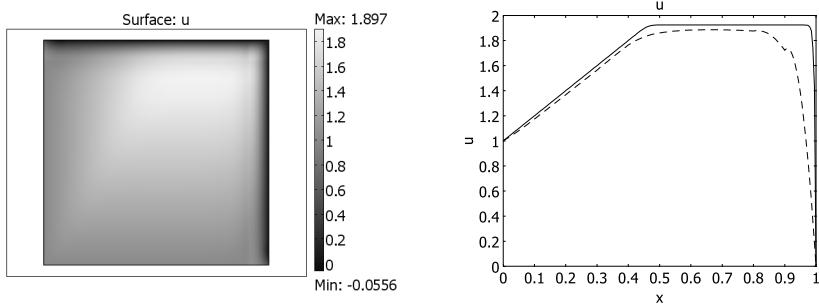

Figure 3-30: Equation 3-5 solved using streamline diffusion and crosswind diffusion. The right plot compares the stabilized solution (dashed line) along $y = 0.8$ with the reference solution (solid line).

Using Units

The COMSOL Multiphysics software supports a number of consistent unit systems, including the SI unit system, which is the default unit system. The physics interface displays the unit for the physical quantities entered in the selected unit system, but by [Using Standard Unit Prefixes and Syntax](#) you can use any available and applicable unit or SI prefix to define your input quantities. In addition to SI units, many English units and units from the CGS (or cgs) system are also available, regardless of the unit system used in the model. All data in the material databases and Material Library product use SI units with declared units using the unit syntax (see [Materials](#)). This makes it possible to use the material data also in models with non-SI unit systems. Regardless of the selected unit system, you can always choose from a list of applicable units for plotting and results evaluation.

In the unit tables, “N/A” means that no unit symbol is available.

- [Unit Systems](#)
- [Indication of Unexpected, Unknown, or Inconsistent Units](#)
- [Setting the Unit System for Models](#)

Using Standard Unit Prefixes and Syntax

STANDARD UNIT PREFIXES

For SI units you can scale data using the standard prefixes for powers of 10 — *kilo*, *mega*, *milli*, or *micro*, for example. Either the full prefix or the symbol can be used, but you must use the same form for the prefix and the unit — that is, [`milliampere`] and [`mA`] are valid but not [`mampere`] or [`milliA`]). In the **Settings** windows for plotting and numerical results, the **Unit** list contains the SI unit for the quantity, including the most common prefixes. The lists also contain applicable non-SI units, which in some cases also support these prefixes — for example, for **g** (gram), **G** (gauss), and **M** (molar).

Use [Table 3-7](#) as a guide for the format to enter.

TABLE 3-7: SI PREFIXES

FULL PREFIX	SYMBOL	FACTOR
yotta	Y	10^{24}
zetta	Z	10^{21}
exa	E	10^{18}
peta	P	10^{15}
tera	T	10^{12}
giga	G	10^9
mega	M	10^6
kilo	k	10^3
hektto	h	10^2
deca	da	10^1
deci	d	10^{-1}
centi	c	10^{-2}
milli	m	10^{-3}

TABLE 3-7: SI PREFIXES

FULL PREFIX	SYMBOL	FACTOR
micro	u	10^{-6}
nano	n	10^{-9}
pico	p	10^{-12}
femto	f	10^{-15}
atto	a	10^{-18}
zepto	z	10^{-21}
yocto	y	10^{-24}

STANDARD UNIT SYNTAX

You can use the unit syntax to specify a quantity with any applicable unit. To do so, append the unit to any constant or variable in a model using a syntax where you enclose the unit in brackets, for example, `200[ft]` and `3e6[kg/m^3]`.

Both the name and the symbol can be used for a unit (but only names that form a single word without spaces or hyphens are possible to use). For example, `2.4[ampere]` and `2.4[A]` are both valid to indicate an electric current in SI units. The SI units can also contain standard prefixes. Appending a unit means that you *multiply* the constant or variable to the left of the unit declaration with this unit. This multiplication takes precedence over other operators so, for example, `1/2[m]` evaluates to 0.5 m^{-1} (`0.5[1/m]`) whereas both `(1/2)[m]` and `1/2*1[m]` evaluate to 50 cm (`0.5[m]` or `50[cm]`). Also, if `L` is a variable defined as `2[m]`, `L[1/s]` evaluates to `2[m/s]`.

The following examples show how to apply the unit syntax:

- Adding two quantities of the same kind that use different units: `0.5[ft]+33[mm]`. The COMSOL Multiphysics software converts the result to the base unit system's length unit.
- Using multiplication with a unit to get consistent units for two quantities that you want to add, for example, `14[kg]+ht.rho[m^3]`, which works if `ht.rho` represents the density for a heat transfer model. You can also concatenate several units, for example, `3.6[N][m]`, which is equivalent to typing `3.6[N*m]` and evaluates to `3.6 N·m`.

For unit names with spaces and hyphens, such as *British thermal unit* and *pound-force*, only use the symbols when declaring units.

It is possible to add constants (without units) to any quantity. The COMSOL Multiphysics software then assumes that this value has the same unit as that quantity (as indicated in the **Settings** window).

All data in the material databases and Material Library product use SI units and this unit syntax.

DECLARING UNITS FOR PARAMETERS, VARIABLES, AND FUNCTIONS

It is important to be aware of the following aspects of unit handling.

When using parameters, variables, and functions in expressions:

- If user-defined parameters or variables are used in the physics, it is good practice to use the unit syntax to define them. The **Settings** windows for parameters and variables display the resulting unit, in the models base unit system, of user-defined parameters and variables. It is important to verify that the variables have the expected unit before using them in the physics settings. The unit of parameters and variables is otherwise undefined.

- Most user-defined and built-in functions expect dimensionless inputs and outputs, so it is good practice to use make inputs, such as time, dimensionless using unit syntax. If the input is not dimensionless, the COMSOL Multiphysics software marks the expression in an orange color and reports an unexpected unit of input. For example, to use the time t as input to a Rectangle function `rect1`, use `[1/s]` to make the input dimensionless: `rect1(t[1/s])`.
- Using properties with undefined units in a model does not affect the numerical results during the analysis, but undefined units are required in the results and visualization stages — expressions involving such parameters and variables are also unitless.
- If other units than the base unit system's units are used or if SI prefixes are included, the conversion to base units also affects the value (quantity) using a scaling factor (and an offset for temperature units). The **Value** column in a **Settings** window for **Parameter** displays the quantity and unit in the base unit system so that you can see the result of the unit conversion. For example, a parameter is defined as `3[ft]`, the result in the **Value** column is **0.9144 m** if the base unit system is SI.

SI Base, Derived, and Other Units

The SI units form an internationally accepted system with seven units for base quantities and a large number of derived units. Use the symbols for these and other units when declaring units in COMSOL (for example, `10[m/s]` uses the SI unit for velocity).

- [Table 3-8](#) lists the SI units for the seven base quantities.
- [Table 3-9](#) lists the SI derived units supported in COMSOL Multiphysics.
- [Table 3-10](#) lists additional units available in the COMSOL Multiphysics software regardless of the unit system in the model. If more than one name or symbol is available, use any of them, except when names contain more than one word or a hyphen. See also the tables with special units for other unit systems than the SI system; special units that are not listed in [Table 3-10](#) are only available when using such non-SI unit systems.
- [Table 3-11](#) lists other SI derived units without special names or symbols.

ADDITIONAL NOTES ABOUT UNITS IN Table 3-9 AND Table 3-10

UNIT NAME	NOTE
British thermal unit	An energy unit defined as the amount of heat required to raise the temperature of one pound (pound-mass) of water by one degree from 60° to 61° Fahrenheit at a constant pressure of one atmosphere. Refer to the British thermal unit using the symbol only (Btu or BTU): for example, 0.28[Btu/(h*in*degF)] for a thermal conductivity.
calorie	Small calorie or gram calorie, which equals 4.184 J. A large calorie or kilogram calorie is 1000 calories (4.184 kJ). Use [kcal] for large calories.
kilopond	The kilopond (kp) or kilogram-force (kpf) is a gravitational metric unit of force. Refer to this unit using kilopond, kp, or kpf only.
kilopound per square inch	The kilopound per square inch (ksi) is a scaled pressure unit derived from psi (1 ksi is equal to 1000 psi). Refer to this unit using the symbol only (ksi).
millidarcy (mD)	Widely used for permeability in petroleum engineering. Typical values for the permeability of porous media are in the range of a few to a few hundred mD. The symbol D represents the debye, a unit for the magnetic dipole moment, and not the darcy unit.
mile	The international statute mile, which equals 1609.344 m.
nautimile	The nautical mile equals 1852 m.
ohm	To declare the SI unit for electric resistance, ohm, use [ohm]. The COMSOL Multiphysics software then displays this as Ω .
inches water	The value of 1 inch of water is defined as the pressure exerted by one inch of water for a pure water density of 1000 kg/m ³ at 4 degrees Celsius and standard gravity of 9.80665 m/s ² . Refer to this unit using the symbol only (inH ₂ O or inAq).
millimeters water	Millimeters water or millimeters, water gauge, is defined as the pressure exerted by one millimeter of water for a pure water density of 1000 kg/m ³ at 4 degrees Celsius and standard gravity of 9.80665 m/s ² . Refer to this unit using the symbol only (mmH ₂ O).
knot	The same as nautical miles per hour.
year	A Gregorian year, which equals 365.2425 days.
gallon (gal)	This is the U.S. liquid gallon which equals 0.003785411784 m ³ ; the Imperial (UK) gallon (imperialgallon, impgal) is equal to 0.00454609 m ³ .
pint and quart	The U.S. liquid pint and U.S. liquid quart, respectively.

TABLE 3-11: EXAMPLES OF SI DERIVED UNITS WITHOUT SPECIAL NAMES

DERIVED QUANTITY	NAME	SYMBOL
acceleration	meter per second squared	m/s ²
amount-of-substance concentration	mole per cubic meter	mol/m ³
area	square meter	m ²
current density	ampere per square meter	A/m ²
heat capacity, specific heat	joule per kilogram kelvin	J/(kg·K)
magnetic field strength	ampere per meter	A/m
mass density	kilogram per cubic meter	kg/m ³
permeability	henry per meter	H/m
speed, velocity	meter per second	m/s
wave number	reciprocal meter	m ⁻¹
volume	cubic meter	m ³

Special British Engineering Units

The base units in the British engineering unit system are identical to the SI units with the following exceptions:

TABLE 3-12: SPECIAL BASE UNITS IN THE BRITISH ENGINEERING UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	foot	ft
mass	slug	N/A
temperature	Fahrenheit	degF

There is one derived unit that differs from the corresponding SI unit:

TABLE 3-13: DERIVED BRITISH ENGINEERING UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
force	pound-force	lbf

The British thermal unit is also available as Btu or BTU.

If the British engineering unit system is the base unit system, the COMSOL Multiphysics software constructs derived units from the applicable SI base units and the units listed in [Table 3-12](#) and [Table 3-13](#). This means, for example, that the unit for voltage displayed in the physics interface is lbf·ft/As rather than V (volt). In a text field that expects a voltage as input, you need to use the unit syntax when entering a numerical value, for example, 10[V].

Special CGSA Units

The base units in the CGSA unit system are identical to the SI units with the following exceptions:

TABLE 3-14: SPECIAL BASE UNITS IN THE CGSA UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	centimeter	cm
mass	gram	g

The CGSA unit system includes the following derived units that differ from the corresponding SI units:

TABLE 3-15: DERIVED CGSA UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
acceleration	galileo	Gal
energy	erg	N/A
force	dyne	dyn
pressure	barye	N/A
speed	kyne	N/A

Special EMU Units

The base units in the EMU unit system are identical to the SI units with the following exceptions:

TABLE 3-16: SPECIAL BASE UNITS IN THE EMU UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	centimeter	cm
mass	gram	g
electric current	abampere, biot	N/A

The EMU unit system includes the following derived units that differ from the corresponding SI units:

TABLE 3-17: DERIVED EMU UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
acceleration	galileo	Gal
capacitance	abfarad	N/A
conductance	absiemens	N/A
electric charge	abcoulomb	N/A
electric resistance	abohm	N/A
electric potential difference, voltage	abvolt	N/A
energy	erg	N/A
force	dyne	dyn
inductance	abhenry	N/A
magnetic flux	abweber	N/A
magnetic flux density	abtesla	N/A
pressure	barye	N/A
speed	kyne	N/A

Special ESU Units

The base units in the ESU unit system are identical to the SI units with the following exceptions:

TABLE 3-18: SPECIAL BASE UNITS IN THE ESU UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	centimeter	cm
mass	gram	g
electric current	statampere, franklin	N/A

The ESU unit system includes the following derived units that differ from the corresponding SI units:

TABLE 3-19: DERIVED ESU UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
acceleration	galileo	Gal
capacitance	stafarad	N/A
conductance	statsiemens	N/A
electric charge	statcoulomb	N/A
electric resistance	stathohm	N/A
electric potential difference, voltage	statvolt	N/A
energy	erg	N/A
force	dyne	dyn
inductance	stathenry	N/A
magnetic flux	statweber	N/A
magnetic flux density	stattesla	N/A
pressure	barye	N/A
speed	kyne	N/A

Special FPS Units

The base units in the FPS unit system are identical to the SI units with the following exceptions:

TABLE 3-20: SPECIAL BASE UNITS IN THE FPS UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	foot	ft
mass	pound	lb
temperature	Fahrenheit	degF

There is one derived unit that differs from the corresponding SI unit:

TABLE 3-21: DERIVED FPS UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
force	poundal	N/A

Special IPS Units

The base units in the IPS unit system are identical to the SI units with the following exceptions:

TABLE 3-22: SPECIAL BASE UNITS IN THE IPS UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	inch	in
mass	pound	lb
temperature	Fahrenheit	degF

Special MPa Units

The base units in the MPa unit system are identical to the SI units with the following exceptions:

TABLE 3-23: SPECIAL BASE UNITS IN THE MPA UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	millimeter	mm
mass	tonne, ton	t

There is one derived unit that differs from the corresponding SI unit:

TABLE 3-24: DERIVED MPA UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
pressure	megapascal	MPa

Special Gravitational IPS Units

The base units in the Gravitational IPS unit system are identical to the SI units with the following exceptions:

TABLE 3-25: SPECIAL BASE UNITS IN THE GRAVITATIONAL IPS UNIT SYSTEM

BASE QUANTITY	NAME	SYMBOL
length	inch	in
mass	GIPS_mass	N/A
temperature	Fahrenheit	degF

The following derived units differ from the corresponding SI units:

TABLE 3-26: DERIVED GRAVITATIONAL IPS UNITS IN COMSOL

DERIVED QUANTITY	NAME	SYMBOL
force	pound-force	lbf
pressure	psi	psi

Switching Unit System

If the unit system is switched during modeling, the COMSOL Multiphysics software does not convert the data in the model (except for length units and angular units in the geometry if specified). All physical constants and data in the material libraries are in SI units and defined using the unit syntax, so you can use them with any unit system because the COMSOL Multiphysics software converts these values to the corresponding values in the model's unit system.

The units of other input data must be declared for the model using the unit syntax (or manually convert the numerical values to the new unit system).

About Temperature Units

The relationship between different temperature units involves an offset in addition to the usual scale factor. The offset is often not important to the physics equations because these equations are concerned only with temperature differences. There are, however, some cases where an absolute or thermodynamic temperature measure must be used. One example is the Stefan-Boltzmann law for blackbody radiation used in radiation boundary conditions.

The SI unit system uses the kelvin, which is an absolute temperature, as the basic unit of temperature. English unit systems use degree Fahrenheit as the basic unit of temperature, which, because the Fahrenheit scale is not absolute, is fine for most purposes except radiation. For such purposes, the Rankine scale provides the corresponding absolute temperature unit. See [Table 3-27](#) for a list of acceptable unit syntax.

TABLE 3-27: TEMPERATURE UNITS

SCALE	UNIT
Celsius	[degC]
Fahrenheit	[degF]
Kelvin	[K]
Rankine	[R] or [Ra]

DIFFERENTIAL VS. ABSOLUTE TEMPERATURE

If the dimension of an expression that includes a unit is temperature or 1/temperature, the COMSOL Multiphysics software interprets the dimension as an absolute temperature. If the dimension is something other than temperature but the unit expression includes temperature, the temperature is a differential temperature; that is, the COMSOL Multiphysics software uses no offset when converting between different temperature units.

The following examples show how the unit conversion works for different expressions that include temperature units:

- 100[degC] is an expression that has temperature as the dimension. The COMSOL Multiphysics software interprets it as an absolute temperature and evaluates it as 373.15 K.
- 373.15[1/K] is interpreted as an absolute inverse temperature (but no conversion is necessary from kelvin to kelvin).

- $373.15[1/\text{degC}]$ evaluates to $100[1/\text{K}]$ using the offset of 273.15 degrees between kelvin and degrees Celsius.
- $100[\text{degC}/\text{K}]$ is dimensionless, and the temperature is therefore a differential temperature; that is, the result is 100 because the conversion uses no offset.
- To make the COMSOL Multiphysics software interpret $100[\text{degC}/\text{K}]$ as an absolute temperature, split the expression using two separate expressions such as $100[\text{degC}][1/\text{K}]$, which equals 373.15. This is also what occurs when you use a variable (TC, for example) defined as $100[\text{degC}]$. TC[1/K] is then also two expressions where both are interpreted as absolute temperature.
- For temperature units that require an offset and a scale factor to be converted to kelvin, it is not possible to convert them simply using a multiplication. While $293.15[\text{K}][1/\text{degF}]$ produces the expected output, 68 (68 degrees Fahrenheit corresponds to 293.15 kelvin), $293.15[\text{K}]*1[1/\text{degF}]$ evaluates to something completely different. As mentioned in the previous point, $293.15[\text{K}/\text{degF}]$ uses no offset and is also usually not the desired expression.

About Editing Geometry Length and Angular Units

The default units are meters for length and degrees for angles. For many applications an independent length unit for the geometry might be required. For example, if the model describes a MEMS device, the natural length unit might be μm (micrometers), or the geometry imported from a CAD file might use another unit than meters. It can also be useful to specify the angular unit in radians instead.

The length unit for the geometry does not affect the units that include length in the physics interfaces or any other part of COMSOL Multiphysics.

- 1 Create or open a model file.
- 2 In the **Model Builder**, under a **Component** node, click the **Geometry** node.
- 3 Under **Units**, select a **Length unit** from the list.
- 4 Select an **Angular unit: Degrees or Radians**.
- 5 Select the **Scale values when changing units** check box to automatically scale for dimensions in the existing geometry.
- 6 Enter a **Default relative repair tolerance** and select a **Geometry representation**.

When importing 3D CAD geometries, you can choose to use the length unit from the CAD file or the length unit from the COMSOL Multiphysics software.

[The Geometry Node](#)

Units and Space Dimensions

Most physics interfaces support 2D (and in some cases also 1D) models in addition to 3D models. The units for intensive physical quantities such as density in the physics interfaces are the same regardless of the space dimension (for density, kg/m^3 in SI units). This makes it possible to use common material property values also in models with other space dimensions than 3D using their well-known, physical units regardless of the dimension you are modeling in. In planar 2D, this means that the implementation includes an implicit unit depth in the out-of-plane direction, except for some physics interfaces (for plane stress in solid mechanics and for electric currents, for example), where the thickness is a user-defined property that defines the volume of the model domain. In axisymmetric models, the volume of the domain is defined by the 2D cross section in the rz -plane that is the

geometry you define for such models. The volume that it defines is the area of the 2D cross section integrated a full 360 degrees in the circumferential direction.

Customizing the COMSOL Desktop

This chapter describes a variety of tasks that can organize and simplify the model building process. For example, set the layout and other features of the COMSOL Desktop using the Preferences settings, change the language and fonts, restrict or allow features to display based on license, or learn about how to edit node names.

In this chapter:

- [Customizing a Model](#)
- [Preferences Settings](#)
- [Advanced Physics, Study, and Results Sections](#)

Customizing a Model

A variety of tasks can be done to organize and simplify the model building process.

- Customizing the Desktop Layout
- Changing Fonts and the Desktop Language
- Editing Node Properties, Names, and Labels
- Custom Grouping of Nodes
- Grouping Nodes by Space Dimension and Type
- Setting the Unit System for Models
- Checking and Controlling Products and Licenses Used

- Preferences Settings
- The Application Libraries Window
- Advanced Physics, Study, and Results Sections
- The COMSOL Desktop

Customizing the Desktop Layout

To customize the COMSOL Desktop environment, you can rearrange the windows by moving, resizing, detaching, or docking each window (see [Adjusting Window Location and Size on the Desktop](#)). Predefined layouts are also available and selected from the **Desktop Layout** menu where you can adjust to a widescreen or regular layout or reset it to the default.

You can also adjust the fonts and the language. See [Changing Fonts and the Desktop Language](#).

CHANGING AND RESETTING THE DESKTOP LAYOUT

The COMSOL Desktop layout can be set to widescreen or regular screen, or you can reset it to its default settings. Resetting can be useful after you have been moving or resizing the windows and want to quickly return to the default. The default settings are restored either for a widescreen layout or a regular screen layout depending on the monitor. Also see [The COMSOL Desktop Menus and Toolbars](#).

From the **Reset Desktop** menu () in the **Layout** section of the **Home** toolbar, or from the **Desktop Layout** submenu in the **Windows** menu in the cross-platform version, select one of the following:

- **Widescreen Layout:** suitable for widescreen monitors. The **Model Builder** window and the **Settings** window display side by side.
- **Regular Screen Layout:** suitable for monitors with a regular screen (4:3). The **Model Builder** window displays on top of the **Settings** window.

To reset the desktop, click **Reset Desktop** () in the **Layout** section of the **Home** toolbar.

To reset the desktop, select **Reset Desktop** or click the **Reset desktop** () button in the main toolbar.

Changing Fonts and the Desktop Language

The COMSOL Multiphysics software uses a default font for texts in plots such as axis labels and titles. It might be necessary to use another default font to display non-Latin characters such as Chinese and Japanese characters. You can also change the Desktop language. You make these changes using [The Preferences Dialog Box](#).

CHANGING THE FONT FOR PLOT LABELS AND TITLES

The **Default font** options are applicable for the text that displays for plots in the **Graphics** window. Changes to those settings are applied when you create a new model. In the **Preferences** dialog box, click **Graphics and Plot Windows**.

- 1 Under **Default font**, select a font **Family** from the list and enter a font **Size** (in points). The default is to use a predefined font family and the font size set to **Default size** in the **Size** list (to use the default system-dependent font size). Depending on the operating system and the installed fonts on the computer, you can select from a number of other font families. You can also choose another font size (6–24 pt) from the **Size** list.
- 2 Click **OK**. The program stores the specified font family and size as a preference setting, so you only have to change it once.

You can also change the setting used for an existing model from the root node's **Settings** window's **Font in Graphics** section. By default, it uses the font specified in the **Preferences** dialog box and the default font size.

- [Plot Titles for Plot Groups and Plot Types](#)
- [The Root Settings and Properties Windows](#)

CHANGING THE COMSOL DESKTOP LANGUAGE

- 1 In the **Preferences** dialog box, click **General**.
- 2 Select an available **Language** for the graphical user interface. The following languages are available: Simplified Chinese, Traditional Chinese, English, French, German, Italian, Japanese, Korean, and Spanish.
- 3 Click **OK**. A message displays indicating that the program must be restarted for the changes to take effect. Click **OK** again, exit and reopen the COMSOL Desktop to display the user interface in the selected language.

If you selected a language during the COMSOL installation, that language becomes the default language when you first start COMSOL Multiphysics.

Editing Node Properties, Names, and Labels

All nodes, except container nodes, have a common set of node properties, some of which can be changed and some system-generated properties that cannot be edited. The **Root** node has additional information that provides an overview of the complete model file. The **Properties** window for the Root node also includes a **Node Properties** section with additional information about the model file. The **Thumbnail** is set from the **Settings** window for Root. See [The Root Settings and Properties Windows](#) for details about the Root node.

EDITING A COMPONENT NAME FOR USE WITH VARIABLES

Use a component **Name** to access variables throughout the model. The name is part of the full reference to variables (for example, when referring to variables in another model component). To edit a component name, in the **Model Builder**, click a **Component** node. The **Settings** window for a **Component** node opens. Edit the default **Name** (comp1, comp2, and so on) as required in the **Name** field.

RENAMING A NODE LABEL

To rename a node in the **Model Builder** (except container nodes with fixed names such as under **Global Definitions**), right-click a node and select **Rename** (救人) or press F2. Enter a **New label** and click **OK**. The **Label** is both updated in the **Model Builder** and in the **Properties** window.

THE NODE PROPERTIES WINDOW

In the **Model Builder**, right-click a node (except “container nodes” such as **Materials**) and select  **Properties** from the context menu. The **Properties** window for that specific node replaces the **Settings** window. The node properties vary by node type.

Node Properties

This section contains these fields:

- The **Label** field defaults to a system label for the node.
- The **Name** field defaults to a system name for the node.
- The **Tag** is a unique system-defined tag for the node, which cannot be changed and is mainly used when using the COMSOL API and the optional LiveLink™ for MATLAB®.
- The **Created** field is system generated and shows the node creation date and time.
- The **Author** field contains the name of the author (creator) of the node. In addition to editing the author name manually, you can make a change for all nodes that you add later on from [The Preferences Dialog Box](#).
- The **Version** and **Comments** fields are empty by default. Enter version numbers or comments to track model changes or changes to specific node contents.

-
- | | |
|---|---|
|  | <ul style="list-style-type: none">• By default, if a node’s settings are described in a report, the comments you enter in the Comments field are also included; see Node Properties for Reports.• For nodes with settings that can be described in reports, toolbars with buttons that let you control the formatting of the text appear above and below the Comments field; for details about these toolbar buttons and how to use them, see Text Formatting Tools. |
|---|---|
-

Returning to the Settings Window

When you are finished editing the properties, right-click the node again and select **Settings** to return to the **Settings** window (or click another node and then click the node again).

-
- | | |
|---|---|
|  | <ul style="list-style-type: none">• The Root Settings and Properties Windows• Settings and Properties Windows for Feature Nodes• To learn about how some of these properties can be viewed, see Displaying Node Names, Tags, and Types in the Model Builder.• Variable Naming Convention and Namespace |
|---|---|
-

Custom Grouping of Nodes

To achieve better overview and easier navigation of the model tree in the Model Builder window, you can create *group nodes* in the Model Builder by selecting and grouping other nodes. You can also create initially empty group nodes and then move other nodes into those group nodes. Group nodes can add organization to the model tree by grouping features that belong together, such as features that belong to a particular part of the geometry or are related to a particular aspect of the physics. You can drag the group nodes to reorder them or drag other nodes to or from the group nodes. Group nodes also make it easy to apply actions to all their members. Right-click a **Group** node (or use the corresponding keyboard shortcuts) and choose **Copy**, **Duplicate**, **Enable**, **Disable**, and **Delete** to make those commands act on the group and all its members. Group nodes under **Results** also make it possible to, for example, evaluate all derived values in a group by right-clicking the **Group** node and choose **Evaluate All**.

The groups only change the view of the model but do not modify the model itself (with the exception that the order of features might be affected).

CREATING GROUP NODES

You can create group nodes using one of these methods:

- Select a set of nodes that are related and appear in the same part of the model tree. Right-click the selected nodes and choose **Group** from the context menu (or press Ctrl+G) to create a **Group** node. The selected nodes become children of the node group.
- Right-click a node (see below) that supports group nodes as subnodes and choose **Node Group** to create an empty **Group** node. You can then move applicable nodes to that node group.

There is only one setting in the **Settings** window for a **Group** node (gear icon). In the **Label** field, type a descriptive node label if desired, so that the label of the **Group** node describes its contents.

You can add node groups to the following parts of the model tree:

- Under **Global Definitions**: Parameters, Variables, Functions, Method Calls, Load and Constraint Groups, Geometry Parts, Mesh Parts, Materials, Extra Dimensions, and Reduced Models.
- Under each type's group node under **Global Definitions**: **Variables**, **Materials**, and so on.
- Under **Definitions** under a component.
- Under each type's group node under **Definitions**: **Variables**, **Functions**, and so on.
- Within a geometry sequence.
- Within a meshing sequence.
- Under **Materials** in a component.
- Under a physics interface.
- Under **Results**.
- Under each type's group node under **Results**: **Data Sets**, **Tables**, and so on.

When you right-click a **Group** node, you can chose to add any applicable nodes as subnode from the context menu.

UNGROUPING AND DELETING GROUP NODES

To ungroup nodes under a group node, right-click the **Group** node and choose **Ungroup**, or press Ctrl+Shift+G. Ungrouping removes the group and moves the subnodes in the group to the group's parent. If you instead right-click the **Group** node and choose **Delete**, or press Delete, the group node and all its subnodes are removed. If it is not possible to delete a subnode, it is then moved to the parent just like when you ungroup a group node.

MOVING NODES TO AND FROM GROUP NODES

You can drag and drop an applicable node into a group, or right-click the node and choose an applicable group node from the context menu's **Move To** submenu.

To move nodes out from a group node to the level above, you can drag and drop it or right-click it and choose **Move Out** (➡). You can also choose **Move Out** for a **Group** node that is placed under a type's node, such as **Variables**.

GROUP NODES AND GROUP BY TYPE AND BY SPACE DIMENSION

When activating **Group by Type** (see below), it will affect **Group** nodes in the following way:

- All applicable nodes that do not belong to a **Group** node will appear under a type node.
- The type nodes appear after the **Group** nodes in the model tree.
- **Group** nodes that contain only a single type of nodes become a child of the type node keeping the order of the features of that type.

The behavior is similar for grouping of physics features by space dimension in the physics interfaces.

Grouping Nodes by Space Dimension and Type

The default setting, found under **Model Builder** in [The Preferences Dialog Box](#) section, disables grouping in new models.

The **Group by Space Dimension** (for physics interface nodes), **Group by Type** (for **Definitions** nodes), or **Ungroup** options are available from the context menu for these features:

- The **Global Definitions** node.
- The **Definitions** node under a **Component**.
- For any physics interface, nodes can be grouped by space dimension — that is, by geometric entity level: **Domains**, **Boundaries**, **Edges** (3D only), or **Points**.

For physics interfaces, when either of these options is selected, the way the nodes are organized changes in the Model Builder and when you right-click to view the context menu.

GROUPING NODES BY SPACE DIMENSION

The default is **Ungroup** in the **Model Builder** for all new models. Right-click and select **Group by Space Dimension** (≡) from the context menu to group the nodes in both the Model Builder and the context menu (see [Figure 4-1](#)).

In [Figure 4-1](#) for the **Electric Currents** interface and when **Group by Space Dimension** is selected, the default **Current Conservation** and **Initial Values** subnodes are included under the **Domains** node, and two boundary level nodes are included under **Boundaries**. However, there are no nodes under **Edges** or **Points** even though these nodes display in the **Model Builder**.

When **Ungroup** (✖) is selected from the context menu (or the default is kept), the tree is flattened and all nodes are ungrouped. Only default physics interface nodes and user-added nodes are included in the **Model Builder** sequence.

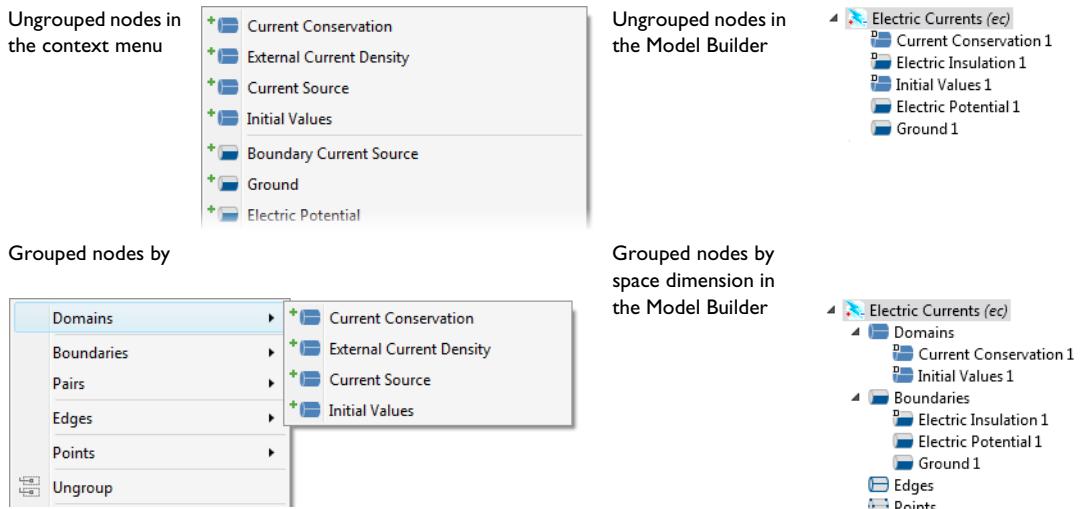

Figure 4-1: The context menu and Model Builder sequence for physics nodes when Group by Space Dimension or Ungroup is selected. For the Global Definitions and Definitions nodes, the same principles apply but the nodes are grouped by type instead.

GROUPING NODES BY TYPE

The same principles apply for the two kinds of **Definitions** nodes as for the physics nodes, except the nodes are grouped by type.

The default is that the nodes are not grouped in the **Model Builder** for all new models. Right-click and select **Group by Type** from the context menu to both group the nodes in the Model Builder and in the context menu. When there is no grouping, only the default **Definitions** or **Global Definitions** nodes and user-added nodes are included in the **Model Builder** sequence as in Figure 4-2.

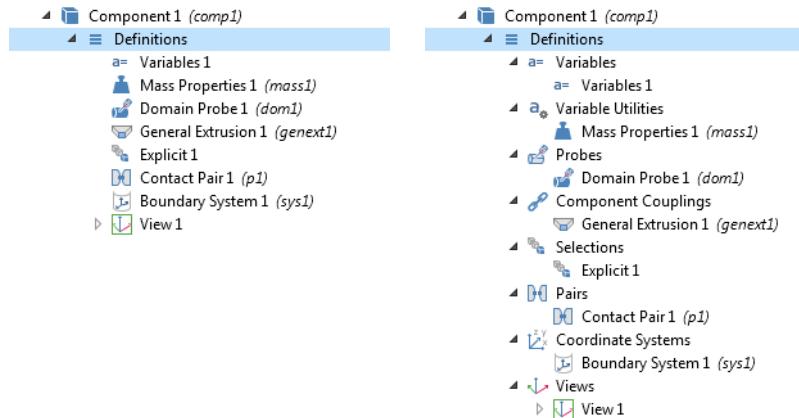

Figure 4-2: Group by Type is not selected (left) and selected (right) from the context menu for the Definitions node.

- Opening Context Menus and Adding Nodes
 - The Physics Nodes
 - The Physics Interfaces
 - Building a COMSOL Multiphysics Model
-

SETTING THE UNIT SYSTEM ON THE GLOBAL LEVEL

To set the unit system for the entire MPH-file on a global level:

- 1 In the **Model Builder**, click the root node (the top node in the model tree). The root node's name is the name of the MPH-file or **Untitled.mph** before you have saved your work.
- 2 In the root node's **Settings** window, select the unit system from the list in the **Unit System** section or **None** to turn off unit support.

SETTING THE UNIT SYSTEM FOR INDIVIDUAL MODEL COMPONENTS

By default, all components in a model use the same global unit system, but it is possible to use different unit systems in each component. To do so, follow these steps:

- 1 In the **Model Builder**, click the top node for a **Component** branch (**Component 1**, for example).
- 2 In the **Settings** window for a **Component** node locate the **Component Settings** section.
- 3 Select the **Override global system** check box, and then select the unit system from the list of unit systems that becomes available.

To make the results of a model independent of the unit system, make sure to define all material properties and other model settings using unit syntax so that all values are interpreted using the intended units. If you switch from a metric unit system, using kelvin as the temperature unit, to a unit system using degrees Fahrenheit as the temperature, or vice versa, the model results are typically not identical because of the offset involved in the conversion of temperature values.

To disable unit support in a model, choose **None** from the list in the **Unit System** section in the root node's **Settings** window and make sure that the corresponding setting for each component is **Same as global system**. If unit support is turned off only for some components (or if the settings at global and component level differ for a model with a single component) unexpected side effects can occur.

- [Using Units](#)
- [The Root Settings and Properties Windows](#)

Checking and Controlling Products and Licenses Used

Open the **Licensed and Used Products in Session** dialog box to view a list of licenses or to block the use of a product. Blocking a license can be useful for consultants who want to duplicate a client's environment while building a model or when collaborating with other users who do not have access to the same set of COMSOL products. You can also use these settings to prevent the use of a module when sharing a floating-network license, for example. It is possible to open and postprocess models that include functionality that you have blocked or that your license does not include. Nodes with functionality that requires a license for a product that is blocked or not available get a **License Error** subnode (✖), where you find information about the missing but required product license. Unless you disable or remove such nodes, it is not possible to re-solve such models.

To open the **Licensed and Used Products in Session** dialog box:

- From the **File** menu, select **Licensed and Used Products** () (Windows users). You can also customize the Quick Access Toolbar and then click the button. See [Windows Toolbars and Menus](#).
- From the main menu, select **Options>Licensed and Used Products** () (macOS and Linux users).

By default, the use of all products is active and the check boxes for all products are selected. The licenses in use are unavailable (you cannot block the use of products with functionality already in use). The main COMSOL Multiphysics product is always in use and therefore has no check box. By default, product licenses that are in use are checked out and unavailable until you start a new model or application by choosing **New** from the **File** menu, for example. To make product licenses that are checked out unavailable during the entire COMSOL Multiphysics session (until you restart COMSOL Multiphysics), select the **Keep checked out licenses throughout session** check box.

Click to clear the check box next to a product to hide or block it from use. Click **Select All** to activate all products. Click **Deselect All** to block all products (except the ones that are already in use). Click **OK** to save the changes or **Cancel** to discard any changes and close the window.

PRODUCT INFORMATION

Click the **Product Information** button to go to the product information pages on the COMSOL website, where you find information about all COMSOL products.

You can also get information about the licensed products from [The About COMSOL Multiphysics Box](#).

BORROW A LICENSE

If you have a floating network license (FNL) or a class kit license (CKL) and your license file has been enabled for borrowing, click **Borrow** to open the **Borrow Licenses** dialog box and borrow licenses from the license server. Select the licenses you want to borrow from the list and specify the number of days you want to keep them. Click **OK** to save.

Remember that other users cannot use the licenses that you have checked out. If you try to borrow a license that has already been borrowed, you receive an error message that shows for which products the license has been borrowed.

Preferences Settings

The Preferences Dialog Box

To make changes to how items are displayed throughout COMSOL edit the following settings in the **Preferences** dialog box as needed.

To open the **Preferences** dialog box:

- Windows users: From the **File** menu, select **Preferences** () You can also customize the Quick Access Toolbar and then click the button. See [Windows Toolbars and Menus](#).
- Cross-platform (macOS and Linux) users: From the main menu select **Options>Preferences** ().

For some settings changes, a message window displays to tell you that COMSOL needs to be restarted for the changes to take effect. For each preference **Settings** window, you can click the **Factory Settings** button to restore the factory default values, or click **Factory Settings for All** to reset all the preferences to the factory default.

As shown in [Figure 4-3](#), the following are available in the **Preferences** dialog box:

- Application Builder
- Application Libraries
- Client Server
- Email
- Files
- Forms
- General
- Geometry
- Graphics and Plot Windows
- Help
- LiveLink Connections
- Methods
- Model Builder
- Multicore and Cluster Computing
- Parametric Sweep
- Part Libraries
- Physics Builder
- Quick Access Toolbar
- Remote Computing
- Results
- Security
- Updates

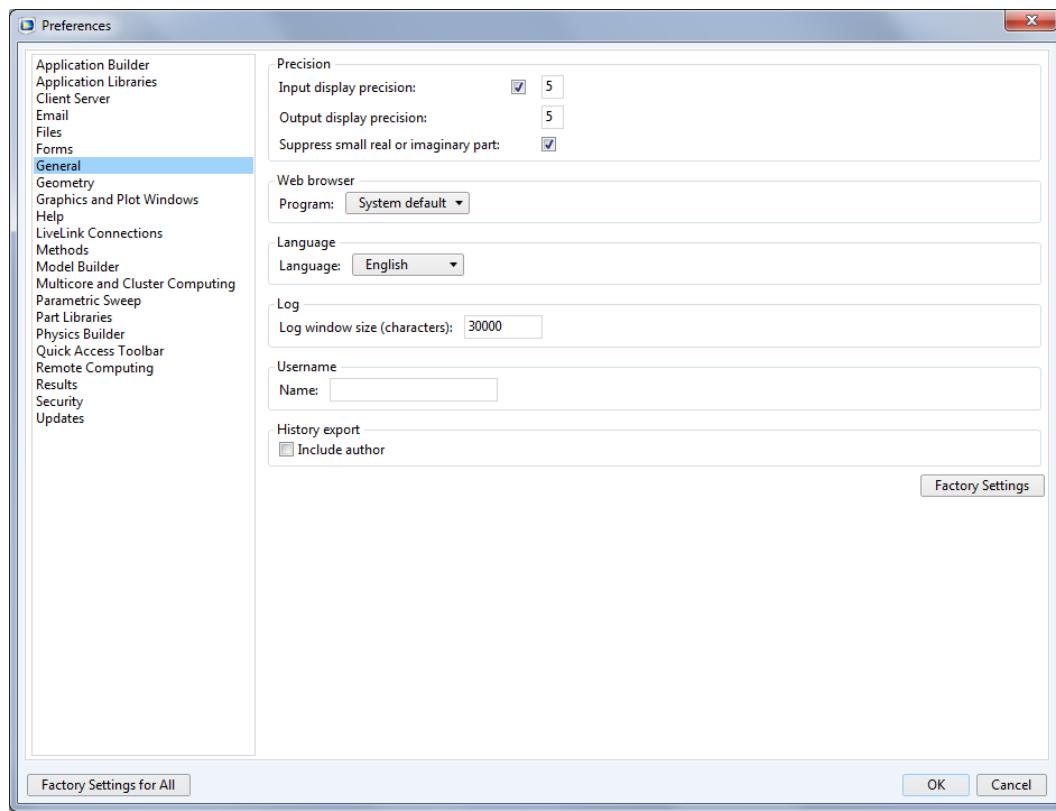

Figure 4-3: The Preferences dialog box.

Importing and Exporting Preferences

You can import and export the preference settings as COMSOL preference files (*.prefs). In the **Preferences** dialog box, click **Import** at the bottom of the dialog box to choose a COMSOL preference file to import from the file chooser window that opens. Then click **Open** to import and use the preferences from the chosen file. Click **Export** at the bottom of the dialog box to choose a COMSOL preference file to export the preference to from the file chooser window that opens. Then click **Save** to save the preferences in the specified file.

By default, most preference settings are migrated from the previous COMSOL Multiphysics version the first time that you start an instance of a new version of COMSOL Multiphysics. See [Preference Migration](#) for more information.

Advanced Physics, Study, and Results Sections

To display the functionality described in this section, click the **Show** button () on the **Model Builder** and then select the applicable option: **Equation Sections**, **Equation View**, **Override and Contribution**, **Stabilization**, **Advanced Physics Options**, **Advanced Study Options**, and **Advanced Results Options**. Each of these are described in this section.

These options are also accessed from [The Preferences Dialog Box](#) in the **Model Builder** section.

EQUATION SECTIONS AND EQUATION NODE

By default all the **Equation** section displays on all physics nodes' **Settings** windows.

Select this option to display the **Equation View** node under all physics nodes in the **Model Builder**.

- [Common Physics Interface and Feature Settings and Nodes](#)
- [Equation View](#)
- [Physics Nodes — Equation Section](#)

ADVANCED PHYSICS OPTIONS

Select **Advanced Physics Options** for a variety of display settings to take effect. It also activates additional options in the context menus or toolbars.

Advanced Settings

The **Advanced** section displays on some physics feature node **Settings** windows. This section does not normally show unless the physics interface contains some advanced options.

Constraint Settings

This section controls how constraints are enforced, usually in boundary conditions. See [Constraint Settings](#) for more information.

Additional Advanced Physics Options

There are additional nodes that can be added to the model either from the context menu (from the **More** or **Global** submenus) or from the **Physics** toolbar.

- **Weak Contribution.** See [Weak Contribution \(PDEs and Physics\)](#) and [Weak Contribution \(ODEs and DAEs\)](#).
- [Weak Constraint](#)
- [Pointwise Constraint](#)
- **Weak Contribution on Mesh Boundaries.** This feature is similar to Weak Contribution but is active on mesh boundaries. See [Weak Contribution \(PDEs and Physics\)](#) and [Weak Contribution \(ODEs and DAEs\)](#).
- [Global Equations](#). Also see [Adding ODEs, DAEs, and Other Global Equations](#).
- [Global Constraint](#). Also see [Symmetric and Nonsymmetric Constraints](#) and [Constraint](#).
- **Weak Contribution.** See [Weak Contribution \(PDEs and Physics\)](#) and [Weak Contribution \(ODEs and DAEs\)](#).
- **Discretization.** See [Discretization \(Node\)](#) and [Settings for the Discretization Sections](#).

ADVANCED STUDY OPTIONS

Select **Advanced Study Options** to enable these options from the context menu, which can then be added to the **Model Builder**: **Job Configurations** and **Solver Configurations**. These nodes also display if they contain content.

- Right-click the **Study** node to enable **Cluster Computing**, **Cluster Sweep**, and **Batch Sweep** and **Batch**.
- Right-click the **Solver Configurations** node to be able to select the option **Create Custom Solver** and add a **Solver** node without any added solver settings or other nodes.
- Right-click any of the **Study Step** nodes to enable the **Multigrid Level** option from the context menu.

ADVANCED RESULTS OPTIONS

To display the **Views** node under **Results**, select **Advanced Results Options**.

- User-Defined Views
- Results Analysis and Plots

STABILIZATION

Select **Stabilization** to display the **Consistent Stabilization** and **Inconsistent Stabilization** sections on the **Settings** windows. If you have access to the Level Set and Mixture Model interfaces, it displays a **Stabilization** section instead.

For detailed information about this feature, see [Numerical Stabilization](#) and [Numerical Stability — Stabilization Techniques for Fluid Flow](#).

OVERRIDE AND CONTRIBUTION

Select **Override and Contribution** to include the section in all physics nodes (for material models, sources, boundary conditions, and so on). For a specific node, the **Override and Contribution** section in its **Settings** window contains lists of other nodes that the node is overridden by, other nodes that the node overrides, and other nodes that contributes with the node (to the total load or flux, for example).

- Physics Exclusive and Contributing Node Types
- Listing Overrides and Contributions
- Overridden Selections

5

Global and Local Definitions

This chapter describes the available functionality in the Global and Component Definitions branches such as parameters, variables, functions, operators, coordinate systems, contact pairs, probes, and infinite elements and PMLs.

In this chapter:

- [Global Definitions, Geometry, Mesh, and Materials](#)
- [Definitions](#)
- [Operators, Functions, and Constants](#)
- [Predefined and Built-In Variables](#)
- [Mass Properties](#)
- [Functions](#)
- [Matrices and Matrix Operations](#)
- [Component Couplings and Coupling Operators](#)
- [Coordinate Systems](#)
- [Identity and Contact Pairs](#)
- [Probes](#)
- [Infinite Elements, Perfectly Matched Layers, and Absorbing Layers](#)
- [Reduced Models](#)

Global Definitions, Geometry, Mesh, and Materials

Depending on the geometric scope, there are different nodes that can be defined in the Model Builder under the top-level **Global Definitions** () node. See [Global Definitions](#) below for a list of available global definitions. The section for local Component [Definitions](#) has all the information about the available features for local definitions.

Global Definitions

Under **Global Definitions** () you add features that apply to the entire model. Add the following features by right-clicking **Global Definitions** and choosing an option from the context menu. You can also access the most widely used functionality using the toolbars (the **Home** toolbar for Windows users and the **Main** toolbar for macOS and Linux users).

- **Parameters** (): User-defined global, scalar values that are used to parameterize any part of the model.
- **Variables** (): User-defined variables that can be used anywhere to simplify the specifications of some properties.
- **Variable Utilities** (). Matrices and matrix operations such as matrix inverse and diagonalization.
- **Thermodynamics** (). This branch contains functionality for thermodynamic calculations. See the documentation for the Chemical Reaction Engineering Module for more information.
- **Functions** (): Function templates for creating user-defined functions based on analytic expressions or imported data, or specifying parameters for common function types such as step functions, ramps, and random functions.
- **Groups** (): Add **Load Group** () and **Constraint Group** () nodes for use in load cases. See [Using Load Cases](#).
- **Geometry Parts** (). Geometry parts for use in 1D, 2D, and 3D model components.
- **Mesh Parts** (). Mesh parts for use in 1D, 2D, and 3D model components.
- **Global Materials** (). For adding materials, layered materials, and material switches at the global level.
- **Reduced Model Inputs** (). For adding **Global Reduced Model Inputs** nodes defining potential inputs to Reduced Model nodes.
- **Reduced Models** (). Here you can choose **Reduced Models Import** () to import a COMSOL Reduced Model file (*.mphrom).
- **Common Model Inputs** (). For modifying the values of common model input properties.

Geometry Parts

The **Geometry Parts** () branch under **Global Definitions** has features to create a geometry **Part** in 3D (), 2D (), and 1D (). You can add these geometry parts as part instances in a geometry sequences in a Component. The **Geometry Parts** node appears when you add a geometry part by right-clicking the **Global Definitions** node and choosing a part from the **Geometry Parts** submenu.

A geometry part can be called (several times) from geometry sequences. You can use geometry parts to make custom parameterized geometric primitives. When calling a part, the input to the part is numerical values of its arguments. The output from the part is a number of geometry objects and a number of selections on these objects.

The part node behaves like a geometry sequence with a few minor differences as described in the [Using Geometry Parts](#) section. You can also link a part from a Model MPH-file.

See also [Creating a Geometry Sequence](#) in the [Geometry Modeling and CAD Tools](#) chapter, which also explains [The Geometry Node](#) and the geometry features.

Mesh Parts

The **Mesh Parts** () branch under **Global Definitions** has features to create a **Mesh Part** in 3D (), 2D (), and 1D (). The **Mesh Parts** node appear when you add a mesh part by right-clicking the **Global Definitions** node and choosing a mesh part from the **Mesh Parts** submenu.

A mesh part contains an imported mesh or meshing sequence and possibly additional meshing operations such as partitions. You can use a mesh part in a geometry sequences by referencing it in an **Import** node. Also, when importing a mesh using an **Import** node in a geometry sequence, a **Mesh Part** node is created.

See [Using Mesh Parts](#) for more information about mesh parts. Also see [Adding, Editing, and Building Meshing Sequences](#) for general information about meshing sequences.

Global Materials

The **Materials** () branch under **Global Definitions** enables you to add materials at the global level. You can add materials in the same way as you do under a **Component** branch, but materials on the global level are available throughout the model and therefore have no **Geometric Entity Selection** section. You can refer to global materials using a **Material Link** node under the **Materials** branch in a component. Using global materials can be useful if you want to use the same materials in several components within a model.

MATERIAL OVERVIEW

This section provides an overview of the materials added under the global **Materials** node. To access global materials in a model component, use a [Material Link](#).

The **Material** column lists the current materials using the materials' node labels from the model tree according to the settings defined in [Displaying Node Names, Tags, and Types in the Model Builder](#).

The **Selection** column for global materials always shows **Global** to indicate the global scope for the materials defined here.

Materials

Definitions

Just as the Global Definitions branch () collects user-defined parameters, variables, and functions accessible at all levels in the Model Builder, the *Definitions* branch () under each Component collects the definitions of variables, functions, and other objects where the geometric scope is restricted to a single component.

Definitions are under the Component branch because several model components can separately be defined in one multiphysics file, for example, when treating certain parts of the whole model in 2D and other parts in 3D.

Definitions which in some way refer to domains in a geometry, the geometry's dimension or its coordinate names must therefore be held apart in different Component branches.

An example of the type of objects you can add under the Definitions branch is a *Selection* node (), which saves selections of geometric entities (boundaries, for example) that relate to a region or part of the overall geometry for reuse in operations later in the modeling process.

Add a **Component** node to the Model Builder, then add definitions with a local scope that apply to that specific model Component. Click or select features either using the **Definitions** toolbar or right-click **Definitions** () and choose an option from the context menu:

Select among the following definition types:

- **Variables** (): Add user-defined variables to simplify the expressions of other variables and properties.
- **Variable Utilities** (). Add variable utilities such as matrices and matrix operations, modal participation factors, and **Mass Properties**, for computing quantities such as volume, mass, center of mass, and moment of inertia
- **View**: Create a user-defined view to visualize the model. See [User-Defined Views](#) in the [Visualization and Selection Tools](#) chapter.
- **Functions** (): Add user-defined functions based on analytic expressions or imported data, or specifying parameters for common function types such as step functions, ramps, and random functions.
- **Probes** (): Add a probe to monitor the development of a scalar-valued quantity (real or complex-valued number) during a dynamic simulation.
- **Component Couplings and Coupling Operators** (): Add nonlocal couplings inside or between Components, in the form of integration, mapping, projection and similar user-defined operators.
- **Selections** (): Create a user-defined set of geometric entities for reuse throughout the model component. See [Creating Named Selections](#) in the [Visualization and Selection Tools](#) chapter.
- **Pairs**: Pairs are only available and necessary when the model geometry is an assembly. See [Identity and Contact Pairs](#). There are two types of pairs:
 - **Contact Pair** (), which specifies two sets of boundaries that can come in contact under deformation. The contact pairs are only available if your license includes the Structural Mechanics Module or the MEMS Module.
 - **Identity Boundary Pair** (), which specifies two boundary selections (also available for edges and points as **Identity Edge Pair** () and **Identity Point Pair** (), respectively) that coincide while belonging to different parts of an assembly. Special boundary conditions connect the physics features in the two parts.
- **Coordinate Systems** (): Create coordinate systems for use in the physics interfaces.
- **Extra Dimensions**: Attach extra dimensions to a selection in the base geometry of a model. See [Using Extra Dimensions](#) for more information.
- **Moving Mesh Features** (). Add moving mesh functionality to model moving meshes in a COMSOL Multiphysics model.

- **Topology Optimization** (). Add **Density Model** () nodes to define the density for topology optimization. This functionality requires the Optimization Module. See the *Optimization Module User's Guide* for more information.
- **Perfectly Matched Layer (PML)** (, **Infinite Element Domain** (, or **Absorbing Layer** (Infinite Elements, Perfectly Matched Layers, and Absorbing Layers.
- **Ambient Thermal Properties**. For specifying ambient thermal properties in heat transfer simulations as user-defined properties or from meteorological data (the meteorological data requires the Heat Transfer Module). The ambient meteorological data comes from the processing of measured data from ASHRAE Weather Data Viewer 5.0 (©2013 ASHRAE, www.ashrae.org. Used with permission.) and ASHRAE Weather Data Viewer 6.0 (©2017 ASHRAE, www.ashrae.org. Used with permission.), given as frequencies of observations, monthly and hourly averaged for several past years of observation. They provide time-dependent weather conditions for more than 8000 stations worldwide in terms of the dry bulb temperature, the dew point temperature, the relative humidity, the wind speed, and the solar direct and diffuse irradiance. See “Ambient Thermal Properties” in the *Heat Transfer Module User's Guide* for more information.
- **Model Input**. For specifying a value for a model input locally, overriding its global value from the [Common Model Inputs](#) node. See [Model Input](#).

About Parameters, Variables, Variable Utilities, and Expressions

PARAMETERS AND VARIABLES

Parameters and *variables* are used to parameterize and organize your model. These are available for the Global Definitions node. Variables are also available in each model component.

Parameters

Parameters are user-defined constant scalars with a global scope that are available for use throughout the Model Builder tree. In particular, they can be used for parameterization in the Geometry, Mesh, and Study branches. Important uses include:

- Parameterizing geometric dimensions
- Parameterizing mesh element sizes
- Defining parametric sweeps

A *parameter expression* can contain: numbers, other parameters, mathematical constants, physical constants, user-defined functions, functions of parameter expressions, unary operators, and binary operators. Parameters can have units. For example, a parameter can be defined as $(\exp(-\pi*i)+a)*c_const$, where *a* is another parameter, but it is often a scalar numerical value for use in a parametric sweep, where that value is updated during the sweep.

Variables

A *variable*'s expression can contain numbers, parameters, mathematical constants, physical constants, other variables, functions of variable expressions, spatial variables, time, unary operators, and binary operators. Variables can also depend on dependent variables (the solution) and their derivatives, and they can have units. For example, a variable can be defined as $\pi*(R_tube^2-r_tube^2)$, where *R_tube* and *r_tube* are two other variables or parameters (for example, defined as 10[mm] and 25[mm], respectively). Variables must be defined so that they return a scalar value when evaluated; that is, the expression defining a variable can be a scalar-valued function such as $2*\pi*x*y$ (in a 2D model), which evaluates to a scalar value for each call with a value of *x* and *y*.

Variables cannot be used in the Geometry and Mesh branches, and only to a limited amount in the Study branch.

Variables can have global or local scope depending on where they are defined. A variable with local scope is limited to a geometric entity level within a model component: the entire component's geometry or selected domains, boundaries, edges (3D only), or points.

Variables with a global scope cannot depend on dependent variables. Such variables can only depend on the time t for time-dependent studies.

Variables can make a model easier to understand by introducing short and descriptive names for complicated expressions or to use a single variable for a quantity that is defined differently in some model domains. Most variables for material properties, coordinates, and other quantities defined on the computational domain are “field variables” — that is, they are defined so that they can vary in space and time and return a scalar value for each set of input values. For example, a built-in variable for the density in a Solid Mechanics interface, `solid.rho`, represents a density ρ as $\rho(x, y, z, t)$ in 3D. You can visualize it in a surface or volume plot, for example, but you cannot use it in an ODE or a global evaluation, even if it should happen to be defined as a constant value. In such a situation, use a component coupling that computes an average quantity or a point probe to obtain a scalar quantity with a global evaluation scope.

NAMING CONVENTIONS, RESERVED NAMES, AND ERRORS

Parameter names and variable names are case sensitive and must begin with a lowercase or uppercase letter (a–z or A–Z). All other characters in the name must be a lowercase or uppercase letter, a number 0–9, or an underscore (_). Dots (.) are also allowed in names but are best avoided because they have a special meaning as delimiters in the namespace. It is possible that the first part of a variable name containing a dot is misinterpreted as a dot symbol for accessing a variable in the namespace.

It is good practice to use descriptive names that are different from the names of built-in functions and constants. Some fundamental built-in mathematical and numerical constants and built-in variables have reserved names; defining a variable using a reserved name is not recommended because it can cause unexpected results. If you use a variable name that is a reserved name (see [Summary of Built-In Variables With Reserved Names](#)), the name appears in orange and if you move the cursor to the name, a tooltip such as **j is a reserved name** appears. The following names are reserved: `eps`, `nan`, `NaN`, `inf`, `Inf`, `i`, `j`, and `pi`. Also, when used in a model, errors about duplicate variable names occur if you defined parameter names using names of built-in variables for the geometry, mesh, and physics (`h`, `dom`, and similar names of built-in variables as well as the names of dependent variables and spatial coordinates in the model).

If the expression contains a syntax error, it appears in red. Syntax errors can be due to illegal characters, mismatched parentheses, and other syntactic errors. The **Error** node (✖), which occurs when trying to solve a model with a syntax error, typically contains information about the position and expression where the syntax error is located.

Parameters

Parameters nodes (`Pi`) are available under **Global Definitions** for creating and defining global parameters. One **Parameter** node is always available, and it cannot be moved or deleted. Additional **Parameter** nodes can be added as desired, if you would like to group parameters in several **Parameter** nodes, perhaps with descriptive labels. This is also useful if you want to use some parameters for preprocessing only and then not include them in parametric sweeps for example (see the **Visibility** section below). You can move and delete **Parameter** nodes that you have added. If you group nodes by type, the **Parameters** nodes appear under **Global Definitions>Parameters**. Right-click a

Parameters Node and choose **Parameter Case** to add **Case** subnodes for parameter cases, which can be useful for parameter switching in a **Parametric Sweep** node (see [Parameter Cases](#)).

The parameter namespace is global, so you cannot use the same parameter name in different **Parameter** nodes. If you do, the parameter name turns red and a **Name already used** tooltip appears.

You can also add a **Parameters** node () under **Results** () for parameters that you want to use for results analysis and postprocessing without the need to update the solution.

Parameters are useful in the following context:

- As parameters in dimensions for geometric primitives or other geometry operations
- As parameters for the mesh generators to, for example, specify the mesh size
- As parameters to control some aspects of the solution process
- To quickly evaluate a mathematical expression, including unit conversion
- In physics interface and feature settings, expressions, and coupling operators
- In expressions when evaluating results

The **Settings** window for **Parameters** includes the following sections.

P A R M E T E R S

Enter values in the **Parameters** table to define parameters used throughout the entire model (or in nodes under **Results** only). In the **Parameters** section you can enter parameters manually or import them from a text file.

- In the **Parameters** table or the field under the table, enter a parameter **Name**.
- In the **Expression** column or field, enter a parameter expression that defines the parameter value, including a unit if desired. You can define a parameter as an expression in terms of numbers, other parameters defined in the same context (and global parameters in the **Parameters** node under **Results**), built-in constants, built-in functions of parameters, built-in constants, and user-defined functions (to access user-defined functions defined under a component use a component scope; that is prefix them with the component's name, such as `comp1.an1(fpar)`). Also add a unit using unit syntax, unless the parameter is unitless. Press Ctrl+Space (or Ctrl+/) or use the **Insert Expression** button () below the table to choose from previously defined parameters, mathematical constants and functions, operators, and physical constants that you can insert into the expression at the position of the cursor.
- The **Value** column displays the value of the parameter in the base unit system.
- In the **Description** column or field, enter an optional description.

You can select one or more parameters and right-click to move them inside this table or to another **Parameters** node, delete the parameters, or cut, copy, and paste the expressions. If there are **Case** subnodes (see [Parameter Cases](#)) added as parameter cases, you can also choose from which **Case** node the parameter values are taken (using the **Set From** submenu).

You can also use the buttons underneath the table to move and remove rows and to clear the table. Also, use the **Move To** button () to move selected parameters to any other available **Parameters** node or to a new **Parameters** node. If there are **Case** subnodes, use the **Set From** button () to pick the parameter values from one of the parameter cases.

Additionally, you can save the parameters to a text file to reuse in other models. Click the **Save to File** button () and enter a **File name** in the **Save to File** dialog box, including the extension .txt. Click **Save** to store the parameters in a text file or in a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ for Excel®. The information is saved in space-separated columns in the same order as displayed on screen. When saving to Excel, an

Excel Save dialog box appears where you can specify the sheet and range and whether to overwrite existing data, include a header, or use a separate column for units.

You can import or load data in files from a spreadsheet program, for example, with the **Load from File** button () and the **Load from File** dialog box that appears. Data must be separated by spaces or tabs. If there is already data in the table, imported parameters are added after the last row. Move or edit rows as needed. If the license includes LiveLink™ for Excel® you can also load parameters from a Microsoft Excel® Workbook spreadsheet. Then an **Excel Load** dialog box appears where you can specify the sheet and range and whether to overwrite existing data. It is also possible to import from a spreadsheet containing a separate column for units.

VISIBILITY

The **Show in parameter selections** check box is selected by default. Clear it if the parameters in this **Parameters** node should not be available for selections in, for example, a **Parametric Sweep** node's **Settings** window.

This section is not available for the **Parameters** node under **Results**.

Parameter Cases

You can right-click a **Parameters** node and choose **Parameter Case** to add one or more **Case** () subnodes. The **Case** nodes' **Settings** window contains a **Parameters** section with the same parameter names as the parameters in the **Parameters** node to which they belong. You can only change the **Expression** column to use a different parameter value in each parameter case. Parameter cases are useful for using different set of parameter values without having to load the parameter values from a set of files. When you have defined multiple parameter cases using **Case** nodes, you can select from which case to set the parameter values in the main **Parameters** node. You also use parameter cases for parameter switching using a **Parametric Sweep** node.

Variables

You can add **Variables** () from either the **Global Definitions** node or the **Definitions** node under the **Component** (local) nodes.

- From the **Home** (Windows users) or **Main** (macOS and Linux users) toolbar click **Variables** and choose **Global Variables** or **Local Variables**.
- Right-click **Global Definitions** and choose **Variables**.
- Under **Component** right-click **Definitions** and choose **Variables**, or click **Local Variables** in the **Definitions** toolbar (Windows users).

Use the **Variables** node to define expressions as user-defined *variables*. Global variables can be used in any context that accepts variable expressions, in all Components and on all geometric entities — provided that their expressions are also global expressions. In contrast, local variables have a specific geometry domain of definition. Such variables can only be used and evaluated in a specific Component, or on selected domains, boundaries, edges, or points.

Global variables are primarily useful for expressions involving parameters that do not depend on the geometry, such as time, or dependent variables in an ODE or algebraic equation. Whenever possible, define variables under **Definitions** in a Component to minimize the risk of variable name conflicts in the global namespace.

Which variables are available for evaluation in postprocessing is decided at the time a solution is created. This means that variables you define do not immediately show up as predefined quantities in results nodes or become available for use in expressions when postprocessing an existing solution. To access the new variables, you must solve the model or update an existing solution by right-clicking a **Study** node () and selecting **Update Solution** ().

GEOMETRIC ENTITY SELECTION (LOCAL DEFINITIONS ONLY)

Select the geometric scope from the **Geometric entity level** list: **Entire model**, **Domain**, **Boundary**, **Edge** (3D only), or **Point**. For all levels except **Entire model**, you must also specify the variables domain of definition either by adding entities to a **Manual** selection or choosing **All boundaries**, for example, from the **Selection** list..

	Variables defined in a Component but with Geometric entity level set to Entire model are in fact global; they can be used anywhere using their full name. For example, if you define variable <code>a</code> in Component 1 in this way, you can refer to it in another Component as <code>comp1.a</code> .
	If a variable is defined on the boundary (with the same name as a variable defined in a domain), it will take precedence, when evaluated on a boundary, over the variable in the domain. If you define a variable <code>v</code> , for example, and the selection is Entire model , you actually define four different variables, representing <code>v</code> in domains, boundaries, edges (3D only), and points.

VARIABLES

In the **Variables** table or the fields under the table, enter variables by defining a variable name under **Name**, an expression that define the variable under **Expression** (see [About Parameters, Variables, Variable Utilities, and Expressions](#)), and (optionally) a description that explains the variable under **Descriptions**. Alternately, you can import variable definitions from a text file. For the expression, press Ctrl+Space (or Ctrl+/) or use the **Insert Expression** button () below the table to choose from a number of applicable variables, parameters, functions, operators, and constants that you can insert into the expression at the position of the cursor. Use other buttons underneath the table to move and remove rows and to clear the table.

Additionally, the **Save to File** button () saves variables to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ for Excel®) for reuse in other models. The information is saved in space-separated columns in the same order as displayed on screen. When saving to Excel, an **Excel Save** dialog box appears where you can specify the sheet and range and whether to overwrite existing data, include a header, or use a separate column for units.

Using the **Load from File** button (, you can import or load data in text files created, for example, by a spreadsheet program. Data must be separated by spaces or tabs. If the license includes LiveLink™ for Excel® you can also load variables from a Microsoft Excel Workbook spreadsheet. Then an **Excel Load** dialog box appears where you can specify the sheet and range, whether to overwrite existing data, and declare if the data is stored using a separate column for units.

	For an example of global variables, see <i>Effective Diffusivity in Porous Materials</i> : Application Library path COMSOL_Multiphysics/Diffusion/effective_diffusivity For examples of local variables see: <ul style="list-style-type: none">• <i>Automotive Muffler</i>: Application Library path COMSOL_Multiphysics/Acoustics/automotive_muffler• <i>Shock Tube</i>: Application Library path COMSOL_Multiphysics/Fluid_Dynamics/shock_tube• <i>Tubular Reactor with Nonisothermal Cooling Jacket</i>: Application Library path COMSOL_Multiphysics/Chemical_Engineering/tubular_reactor
---	--

Variable Utilities

You can add **Variable Utilities** () from the **Definitions** node under the **Component** (local) nodes. If **Group by Type** is active, the variable utility nodes appear in the **Variable Utilities** () branch.

Right-click **Variable Utilities** and, or right-click **Definitions** and, from the **Variable Utilities** submenu, choose from the following variable utility nodes:

- **Matrix**: for defining a matrix variable by entering the components of the matrix. See [Matrix](#).
- **Matrix Inverse**: for computing a matrix inverse from an input matrix. See [Matrix Inverse](#).
- **Matrix Diagonalization**: for diagonalization of a matrix, computing the eigenvalues and eigenvectors of a symmetric 3x3 matrix from an input matrix. See [Matrix Diagonalization](#).
- **Matrix Decomposition (SVD)**: for computing a matrix decomposition using SVD (singular value decomposition) from an input matrix. This node computes singular values, singular vectors, a rotation matrix, and a stretch matrix from a general 1x1 to 9x9 matrix. See [Matrix Decomposition \(SVD\)](#).
- **Participation Factors**: for computing modal participation factors. See [Participation Factors](#) below.
- **Response Spectrum**: for computing modal participation factors and setting up data for a response spectrum analysis. See [Response Spectrum](#) below.
- **Mass Properties**: for computing mass properties such as mass, volume, and center of mass. See [Mass Properties](#).

Common Model Inputs

The **Common Model Inputs** node () can be added under **Global Definitions** to define constant values for model inputs that are common for the entire model. Right-click **Global Definitions** and choose **Common Model Inputs** to display or hide the **Common Model Inputs** node. The **Common Model Inputs** node also appears if it is hidden when a model input is requested (for example, from a material that is dependent on temperature).

The common model inputs include most physical properties and are always available with a scalar default value. In the settings for the **Common Model Inputs** node, you can change the default values, and you can also override them locally either by a dependent variable (field variable) for the same quantity or by a locally defined **Model Input** node (see [Model Input](#)).

Common model inputs are useful in the following ways:

- Model inputs have a central representation as a variable. The value of a model input variable can differ between components and geometry regions.
- There is no need, in most cases, to use a local model input in the physics interfaces.
- Any material using a model input will use the common model input, unless something else is specified.
- It makes it possible to use, for example, a temperature-dependent material property in a PDE interface, which can be evaluated as a common model input, possibly overridden by a local model input or by a temperature field from a Heat Transfer interface defined in the same component geometry.

The main **Materials** node under each component contains a **Model Input Contribution** section, in which all model input contributions are listed with the provider and value or expression used for all domains in the component (see [Materials](#)).

Click the **Reset All** button () to reset all values to their default values.

The **Settings** window contains the following sections:

REQUESTED MODEL INPUTS

In this section any requested model inputs from the physics or materials appear.

The table of requested model inputs contains the following columns:

- The **Model input** column contains the names of the requested model inputs such as **Temperature**.
- The **Expression** column contains the expression that defines the model input, such as **comp1.T** for a temperature field in Component 1. The column will be editable if it does not contain an automatically matched quantity such as **comp1.T** for an existing temperature field. For example, if the expression comes from a **Model Input** node under **Definitions** in a model component. If the model input is editable, click the **Edit Expression** button () underneath the table. You can also right-click the cell and choose, for example, **Edit Expression for Remaining Selections** to enter another value for remaining selections in the text field for the model input under **Expression for remaining selections** in the **Browse Model Inputs** section. The **Expression** column can also contain the value **Mixed**, which indicates an expression that is requested in two selections, and the expression is different on each selection (for example, it is a temperature field in one domain and a user-defined model input in another).
- The icon column contains an icon for the material or physics that requested the model input.
- The **Selection** column contains the geometric selection for the model input.
- The **Requested by** column contains the node that requested this model input. Click the **Go to Requesting Node** button () to move to that node.

Click the **Create Model Input** button () to create a local **Model Input** node that you can use to override the global model input in some part of the component geometry.

BROWSE MODEL INPUTS

In this section, you can select a physical quantity (all physical quantities can serve as model inputs) from the **General**, **Acoustics**, **Maxwell**, **Solid**, and **Transport** folders. You can also type in a physical quantity in the text field above the list and click the **Filter** button () to filter the list of model inputs. If the **Show Only Contributed and Requested Model Inputs** button () is active, the list of physical quantities only contains such physical quantities that are either contributed or requested model inputs.

When you have selected a model input, its default value is displayed below the list of model inputs under **Expression for remaining selection**, for example. The default value is a constant value, which can be useful, for example, for evaluating an expression that used a model input before computing a solution. For many model inputs, the default value is 0, but for **Temperature**, for example, it is 293.15 K (20 degrees Celsius). You can change that value if you want to use another value for the temperature as a common model input, for example. Click the **Reset to Default** button () to reset the value to the default value for that model input.

In the table under **Model input contributions**, the left column contains value of the model input, the **Selection** column contains its selection (**Remaining**, for example). The icon column contains an icon that represents the interface, or the **Common Model Input** node itself (, that contains the provider that contributed a model input. The **Provider** column contains the name of the provider of the model input.

Every physical quantities that can act as model inputs declares and defines a common variable that is always available (for example, **minput.T** for the temperature T). Any material property that depends on a model input quantity can be evaluated using the common variable.

About Model Inputs

Model Input

Add a **Model Input** () under **Definitions** to define a local value for a model input in part of or all of the geometry in the component and for all physics interfaces in that component, overriding its value from the **Common Model Inputs** node and any value based on a dependent value from a physics interface. This functionality can be useful if

you want to, for example, override a multiphysics coupling or specify a custom model input (such as a temperature defined by a PDE) for a multiphysics simulation.

The default **Name** is the same as the selected model input quantity (T , for example, for temperature).

The **Settings** window includes the following sections:

GEOMETRIC ENTITY SELECTION

In this section, define the geometric entities where this model input definition is active.

OVERRIDE

This section lists any other **Model Input** nodes that this node overrides or is overridden by. Only **Model Input** nodes with the same model input quantity and the same or an overlapping geometric entity selection can override or be overridden.

DEFINITION

Click the **Select Quantity** button () to select a model input quality from the **General**, **Acoustics**, **Maxwell**, **Solid**, or **Transport** folder, or type a filter text and click the **Filter** button () to filter the list of model inputs. Then type a value or expression in the text field for the selected model input quantity. Under **Variable name**, the variable name that represent this model input (`minput.T` for temperature, for example) appears.

Participation Factors

Add a **Participation Factors** node () under **Definitions>Variable Utilities** in a model component for computing modal participation factors in structural simulations. Participation factors are measures that relate to the energy contained within each resonant mode (they represent the amount of system mass participating in a particular mode). See *Modal Participation Factors* in the *Structural Mechanics Module User's Guide* for more information.

When you add an Eigenfrequency study a **Participation Factors** node is automatically created.

The **Settings** window contains the following section:

CENTER OF ROTATION

From the **Center of rotation** list, choose **Center of mass** (the default) or **User defined** for defining the coordinates of the center of rotation in the **X**, **Y**, and **Z** field (the default names in a 3D structural mechanics model).

Response Spectrum

Add a **Response Spectrum** node () under **Definitions>Variable Utilities** in a model component to prepare for response spectrum evaluations in structural simulations. This node serves two purposes:

- It defines participation factor variables, similar to a **Participation Factors** node. These variables are available for standard result presentation but are also used by the special response spectrum data sets.
- You can generate the model features necessary for computing *missing mass correction*, a method used in some response spectrum evaluations.

The **Settings** window contains the following section:

RESPONSE SPECTRUM

You need to access the settings in this node only if you are going to include a missing mass correction in your response spectrum analysis. In this case, a synchronization between the eigenfrequency study and the stationary study used to compute the forces from missing mass is needed.

From the **Eigenfrequency study** list, choose the study used for computing the eigenfrequencies to be used in the response spectrum evaluation. When the **Response Spectrum** node has been automatically created through the addition of a Response Spectrum study, the selection will as a default point to the corresponding study.

For creating the additional features needed for including missing mass correction into your response spectrum evaluation, click the **Create** button. The effect of doing so is:

- A number of load groups are created.
- A number of **Gravity** nodes are added to all structural mechanics interfaces in the component.
- A new study sequence is added for the stationary analyses needed to compute the missing mass correction.

The **Response Spectrum** node requires the Structural Mechanics Module.

For more information:

- See [Performing a Response Spectrum Analysis](#) in the *Structural Mechanics Module User's Guide* for a general overview of how to set up a response spectrum analysis.
- See *Modal Participation Factors* in the *Structural Mechanics Module User's Guide* for a discussion about participation factors.
- See [Response Spectrum 2D and Response Spectrum 3D](#) for information about the data sets used for response spectrum evaluation.

Common Settings for the Definitions Nodes

Many nodes that can be added under the **Global Definitions** node or a **Definitions** node at the Component level share the same settings or use settings generally found throughout COMSOL Multiphysics.

COMMON BUTTONS ON THE SETTINGS WINDOWS

The following buttons are available on many of the **Settings** windows and are mostly self explanatory. These are not explicitly described or explained for every node.

- [About Selecting Geometric Entities](#)
- [The Model Builder](#)
- [Creating Named Selections](#)

- In general, use the **Move Up** (↑), **Move Down** (↓), and **Delete** (⌫) buttons and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**.
- The **Add** button (✚) under a list of named selections opens an **Add** dialog box that contains all existing selections for the same geometric entity level.
- To save the contents of a table, click the **Save to File** button (💾) and enter a **File name** in the **Save to File** dialog box, including the extension .txt. Click to **Save** the text file. The information is saved in space-separated columns in the same order as displayed on screen.
- Use the **Load from File** button (📁) and **Load from File** dialog box to import data in text files, generated by, for example, a spreadsheet program. Data must be separated by spaces or tabs (or be in a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ for Excel®).

NAME

For **Mass Properties**, **Participation Factors**, **Matrix** and other matrix utility nodes, **Selections**, and **Coordinate Systems**, you must specify a **Name** that is unique within the model component where the feature is added. You can use this Name in expressions, and it is also the node's **Tag**. A unique default **Name** is always generated when the node is created. See [Settings and Properties Windows for Feature Nodes](#) and [Displaying Node Names, Tags, and Types in the Model Builder](#) for more information.

For **Coordinate Systems** it provides a namespace for variables created by the coordinate system. The default **Name** is **sys1**. For example, the determinant of the coordinate system's transformation matrix can typically be accessed in equations and postprocessing as **sys1.detT**. See the **Equation View** subnode for a complete list of available variables.

To display the **Equation View** node under all nodes creating variables, click the **Show** button and select **Equation View**. See also [Equation View](#).

FUNCTION NAME

For all **Functions** you must specify a **Function name** that is unique on the global level or within the model component where the feature is added. You can use this function name or operator name in expressions, and it is also the node's **Tag**. A unique default function name or operator name is always generated when the node is created. See [Functions](#).

VARIABLE NAME

For all **Probes** you must specify a **Variable name** that is unique within the model component where the feature is added. You can use this Variable name in expressions, and it is also the node's **Tag**. A unique default Variable name is always generated when the node is created. See [Probes](#).

OPERATOR NAME

For all **Component Couplings** you must specify an **Operator name** that is unique within the model component where the feature is added. You can use this Operator name in expressions, and it is also the node's **Tag**. A unique default Operator name is always generated when the node is created. See [Component Couplings and Coupling Operators](#).

PAIR NAME

For all **Pairs** you must specify a **Pair name** that is unique within the model component where the feature is added. You can use this Pair name in expressions, and it is also the node's **Tag**. A unique default Pair name is always generated when the node is created. See [Identity and Contact Pairs](#).

To display the **Equation View** node under all nodes creating variables, click the **Show** button and select **Equation View**. See also [Equation View](#).

- [Settings and Properties Windows for Feature Nodes](#)
- [Displaying Node Names, Tags, and Types in the Model Builder](#)
- [Editing Node Properties, Names, and Labels](#)

Operators, Functions, and Constants

Many built-in mathematical and logical operators, functions, and constants can be used to specify parameters, variables, equation coefficients, and material properties. These tables list the unary and binary operators ([Table 5-1](#) and [Table 5-2](#)), special operators ([Table 5-8](#)), mathematical functions and constants ([Table 5-6](#)), and physical constants predefined as variables ([Table 5-7](#)) that are available in COMSOL Multiphysics. See also [Component Couplings and Coupling Operators](#) for information about coupling operators.

Unary, Binary, and List Operators and Their Precedence Rules

TABLE 5-1: UNARY OPERATORS

OPERATOR	DESCRIPTION
+	Unary plus
-	Unary minus
!	Logical not

The binary operators include arithmetic and logical operations.

TABLE 5-2: BINARY OPERATORS

OPERATOR	DESCRIPTION
+	Plus
-	Minus
*	Multiply
/	Divide
^	Power
==	Equal
!=	Not equal
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
&&	Logical and
	Logical or

A comparison using a binary operator can be, for example $x < 1$, which returns 1 (true) if x is smaller than 1 and 0 (false) otherwise. For a composite comparison such as $0 < x < 1$, you can achieve it using $(0 < x) * (x < 1)$. An expression like $0 < x < 1$ is possible to use but is evaluated as $(0 < x) < 1$, which for an x in the interval is interpreted as 1 < 1 and thus returns 0 instead of 1 for all such value of x .

The following operators are used for precedence, grouping, lists, and unit definitions:

TABLE 5-3: GROUPING, LIST, AND UNIT OPERATORS

OPERATOR	DESCRIPTION
()	Parentheses for controlling precedence in expressions
{}	Vector and tensor expressions
,	Element separator in lists
.	Scoping operator
[]	Unit

The following list shows the precedence order for the operators above:

TABLE 5-4: PRECEDENCE LEVELS

PRECEDENCE LEVEL	SYMBOL	DESCRIPTION
1	() { } .	Grouping, lists, namespace
2	$^$	Power
3	! - +	Unary: logical not, minus, plus
4	[]	Unit
5	* /	Multiplication, division
6	+ -	Addition, subtraction
7	< <= > >=	Comparisons: less than, less than or equal, more than, more than or equal
8	== !=	Comparisons: equal, not equal
9	&&	Logical and
10		Logical or
11	,	Element separator in lists

Mathematical and Numerical Constants

The following table includes the built-in mathematical and numerical constants. The names of these constants are reserved names. You cannot use such reserved constant names when creating user-defined variables and parameters.

TABLE 5-5: MATHEMATICAL AND NUMERICAL CONSTANTS

NAME	DESCRIPTION
eps	Floating point relative accuracy (machine epsilon, 2^{-52} or about $2.2204 \cdot 10^{-16}$, for double floating point numbers).
i, j	Imaginary unit, $\sqrt{-1}$.
inf, Inf	Infinity, ∞ . A value larger than what can be handled with floating-point representation.
NaN, nan	Not-a-number. An undefined or unrepresentable value such as the result of $0/0$ or inf/inf .
pi	Pi (about 3.141592653589793).

Mathematical Functions

The following list includes the built-in mathematical functions that you can use when defining variables or directly in expressions in the physics interface or feature settings, for example. The function names are reserved names that cannot be used for user-defined functions, but they can be used for variable and parameter names.

TABLE 5-6: MATHEMATICAL FUNCTIONS

NAME	DESCRIPTION	SYNTAX EXAMPLE
abs	Absolute value	abs(x)
acos	Inverse cosine (in radians)	acos(x)
acosh	Inverse hyperbolic cosine	acosh(x)
acot	Inverse cotangent (in radians)	acot(x)
acoth	Inverse hyperbolic cotangent	acoth(x)
acsc	Inverse cosecant (in radians)	acsc(x)
acsch	Inverse hyperbolic cosecant	acsch(x)
arg	Phase angle (in radians)	arg(x)
asec	Inverse secant (in radians)	asec(x)
asech	Inverse hyperbolic secant	asech(x)

TABLE 5-6: MATHEMATICAL FUNCTIONS

NAME	DESCRIPTION	SYNTAX EXAMPLE
asin	Inverse sine (in radians)	asin(x)
asinh	Inverse hyperbolic sine	asinh(x)
atan	Inverse tangent (in radians)	atan(x)
atan2	Four-quadrant inverse tangent (in radians)	atan2(y,x)
atanh	Inverse hyperbolic tangent	atanh(x)
besselj	Bessel function of the first kind	besselj(a,x)
bessely	Bessel function of the second kind	bessely(a,x)
besseli	Modified Bessel function of the first kind	besseli(a,x)
besselk	Modified Bessel function of the second kind	besselk(a,x)
ceil	Nearest following integer	ceil(x)
conj	Complex conjugate	conj(x)
cos	Cosine (argument in radians)	cos(x)
cosh	Hyperbolic cosine	cosh(x)
cot	Cotangent (argument in radians)	cot(x)
coth	Hyperbolic cotangent	coth(x)
csc	Cosecant (argument in radians)	csc(x)
csch	Hyperbolic cosecant	csch(x)
erf	Error function	erf(x)
erfinv	Inverse error function	erfinv(x)
exp	Exponential function e^x . That is, exp(1) is the mathematical constant e (Euler's number).	exp(x)
floor	Nearest previous integer	floor(x)
gamma	Gamma function	gamma(x)
imag	Imaginary part	imag(u)
log	Natural logarithm	log(x)
log10	Common logarithm (base 10)	log10(x)
log2	Base-2 logarithm	log2(x)
max	Maximum of two arguments	max(a,b)
min	Minimum of two arguments	min(a,b)
mod	Modulo operator	mod(a,b)
psi	Psi function and its derivatives	psi(x,k)
random	Random function, uniform distribution	random(x,y)
randomnormal	Random function, normal (Gaussian) distribution	randomnormal(x,y)
range	Create a range of numbers	range(a,step,b)
real	Real part	real(u)
round	Round to closest integer	round(x)
sec	Secant (argument in radians)	sec(x)
sech	Hyperbolic secant	sech(x)
sign	Signum function	sign(u)
sin	Sine (argument in radians)	sin(x)
sinh	Hyperbolic sine	sinh(x)

TABLE 5-6: MATHEMATICAL FUNCTIONS

NAME	DESCRIPTION	SYNTAX EXAMPLE
sqrt	Square root	sqrt(x)
tan	Tangent (argument in radians)	tan(x)
tanh	Hyperbolic tangent	tanh(x)

Physical Constants

Physical constants are fundamental, universal constants that represent physical quantities. COMSOL Multiphysics includes the most widely used physical constants as built-in constants. [Table 5-7](#) lists all supported physical constants with their names, symbol (variable name), value, and SI unit. The values are taken from Ref. 1 and include the SI unit.

TABLE 5-7: PHYSICAL CONSTANTS

NAME	SYMBOL	VALUE
Acceleration of gravity	g_const	9.80665[m/s^2]
Avogadro constant	N_A_const	6.022140857e23[1/mol]
Boltzmann constant	k_B_const	1.38064852e-23[J/K]
Characteristic impedance of vacuum (impedance of free space)	Z0_const	376.730313461...[ohm] (mu0*c)
Electron mass	me_const	9.10938356e-31[kg]
Elementary charge	e_const	1.6021766208e-19[C]
Faraday constant	F_const	96485.33289[C/mol]
Fine-structure constant	alpha_const	7.2973525664e-3
Gravitational constant	G_const	6.67408e-11[m^3/(kg*s^2)]
Molar volume of ideal gas (at 273.15 K and 1 atm)	V_m_const	22.413962e-3[m^3/mol]
Neutron mass	mn_const	1.674927471e-27[kg]
Permeability of vacuum (magnetic constant)	mu0_const	4*pi*1e-7[H/m]
Permittivity of vacuum (electric constant)	epsilon0_const	8.854187817e-12[F/m]
Planck's constant	h_const	6.626070040e-34[J*s]
Planck's constant over 2 pi	hbar_const	1.054571800e-34[J*s]
Proton mass	mp_const	1.672621898e-27[kg]
Speed of light in vacuum	c_const	299792458[m/s]
Stefan-Boltzmann constant	sigma_const	5.670367e-8[W/(m^2*K^4)]
Universal gas constant (molar gas constant)	R_const	8.3144598[J/(mol*K)]
Wien displacement law constant	b_const	2.8977729e-3[m*K]

Built-In Operators

There are special built-in operators available for modeling and for evaluating results; these operators are similar to functions but behave differently. Many physics interfaces use these operators to implement equations and special functionality. See [Table 5-8](#) and the detailed descriptions that follow.

TABLE 5-8: BUILT-IN OPERATORS

OPERATOR	DESCRIPTION	LINK TO MORE INFORMATION
<code>adj(expr)</code>	Evaluate expression using the adjoint sensitivity.	adj
<code>at</code>	Access the solution at any time.	at
<code>atlocal</code>	Evaluate expression at given local coordinates in each mesh element.	atlocal
<code>attimemax</code> <code>attimemin</code>	Evaluates an expression at the time where another expression achieves its maximum or minimum.	attimemax and attimemin
<code>atxd, atonly, noxd</code>	Evaluation of expressions in extra dimensions.	atxd, atonly, and noxd
<code>ballint(<i>r</i>,<i>expr</i>)</code> , <code>ballavg(<i>r</i>,<i>expr</i>)</code> , <code>circint(<i>r</i>,<i>expr</i>)</code> , <code>circavg(<i>r</i>,<i>expr</i>)</code> , <code>diskint(<i>r</i>,<i>expr</i>)</code> , <code>diskavg(<i>r</i>,<i>expr</i>)</code> , <code>sphint(<i>r</i>,<i>expr</i>)</code> , <code>sphavg(<i>r</i>,<i>expr</i>)</code>	Evaluates the integral or average of the expression on the specified shape with radius <i>r</i> .	ball , circle , disk , and sphere
<code>bdf(expr,<i>i</i>)</code>	Apply backward differentiation formula of order <i>i</i> on expression.	bdf
<code>bndenv(expr)</code>	Evaluates the expression <i>expr</i> at the coordinates of a particle or ray at a boundary.	env , bndenv , and noenv
<code>centroid(expr)</code>	Evaluates the expression <i>expr</i> in the centroid of the mesh element to which the point belongs.	centroid
<code>circumcenter(expr)</code>	Evaluates the expression <i>expr</i> in the circumcenter of the mesh element to which the point belongs.	circumcenter
<code>d(f,x)</code>	Differentiation operator. Differentiation of <i>f</i> with respect to <i>x</i> .	Differentiation Operators: d, pd, and dtang
<code>depends(expr)</code> <code>depends(expr,var)</code>	True if expression <i>expr</i> depends on the solution or <i>var</i> , respectively.	depends
<code>dest(expr)</code>	Evaluate parts of an integration coupling expression on destination side.	dest
<code>down(expr)</code>	Evaluate expression as defined in adjacent downside.	up and down
<code>dtang(f,x)</code>	Tangential differentiation of an expression <i>f</i> defined on a boundary with respect to a spatial dimension <i>x</i> .	Differentiation Operators: d, pd, and dtang
<code>emetric(exprx,expry)</code> <code>emetric(exprx,expry,exprz)</code>	The square of the length of the global vector (<i>exprx</i> , <i>expry</i> , <i>exprz</i>) computed in the mesh element's own metric.	emetric
<code>env(expr)</code>	Evaluates the expression <i>expr</i> at the coordinates of a particle or ray in a domain.	env , bndenv , and noenv
<code>error('string')</code>	Generates an error with error message <i>string</i> .	error

TABLE 5-8: BUILT-IN OPERATORS

OPERATOR	DESCRIPTION	LINK TO MORE INFORMATION
<code>fsens(<i>p</i>)</code> <code>fsensimag(<i>p</i>)</code>	Functional sensitivity with respect to control variable <i>p</i> . Functional sensitivity with respect to imaginary part of control variable <i>p</i> .	fsens and fsensimag
<code>gpeval(<i>gporder,expr</i>)</code> <code>gpeval(<i>gporder,expr,exorder</i>)</code>	Evaluate expression in the specified Gauss point pattern and extrapolate the result to the input evaluation points.	gpeval
<code>if(<i>cond,expr1,expr2</i>)</code>	Conditional expression evaluating the second or third argument depending on the value of the condition.	if
<code>integrate(<i>expr,var,lower,upper</i>)</code>	Evaluate integral of general expression with respect to an integration variable over a real interval specified by lower and upper limits.	integrate
<code>isdefined(<i>variable</i>)</code>	Returns one where the variable is defined and zero where it is not defined.	
<code>isinf(<i>expr</i>)</code>	True if expression evaluates to infinity.	isinf and isnan
<code>islinear(<i>expr</i>)</code>	True if expression is a linear function of the solution.	islinear
<code>isnan(<i>expr</i>)</code>	True if expression evaluates to NaN (not-a-number).	isinf and isnan
<code>jacdepends(<i>expr</i>)</code> <code>jacdepends(<i>expr,var</i>)</code>	True if the derivative of the expression <i>expr</i> with respect to the solution depends on the solution or <i>var</i> , respectively.	jacdepends
<code>lindev</code>	Evaluate an expression linearized at the linearization point (when a linearization point is stored in the solution).	lindev
<code>linper</code>	Marks a load term to be used in a Linear perturbation solver.	linper
<code>linpoint</code>	Access the linearization point (when a linearization point is stored in the solution).	linpoint
<code>linsol</code>	Access the standard solution (for example inside <code>linpoint</code> or <code>lintotal</code>).	linsol
<code>lintotal</code>	Access the sum of the linearization point and linear perturbation.	lintotal
<code>lintotalavg</code>	Evaluate average of <code>lintotal(<i>expr</i>)</code> over all phases.	lintotalavg
<code>lintotalpeak</code>	Evaluate maximum of <code>lintotal(<i>expr</i>)</code> over all phases.	lintotalpeak
<code>lintotalrms</code>	Evaluate RMS of <code>lintotal(<i>expr</i>)</code> over all phases.	lintotalrms
<code>linzero</code>	Evaluate expression with zero solution.	linzero
<code>mean(<i>expr</i>)</code>	Mean value of expression as evaluated on adjacent boundaries.	mean
<code>nif(<i>cond1,expr1,...,condn,exprn,exprn+1</i>)</code>	Nested if operator. Evaluating the <i>expr</i> after the first <i>cond</i> to return true.	nif
<code>noenv(<i>expr</i>)</code>	Evaluates an expression <i>expr</i> that is defined only on particles or rays, not the domain or boundary where the particles or rays are located.	env , bndenv , and noenv
<code>nojac(<i>expr</i>)</code>	No contribution to the Jacobian.	nojac

TABLE 5-8: BUILT-IN OPERATORS

OPERATOR	DESCRIPTION	LINK TO MORE INFORMATION
<code>pd(f,x)</code>	Differentiation operator. Differentiation of f with respect to x . No chain rule for dependent variables.	Differentiation Operators: d, pd, and dtang
<code>ppr</code>	Polynomial-preserving derivative recovery.	ppr and pprint
<code>pprint</code>	Polynomial-preserving derivative recovery within each domain group.	ppr and pprint
<code>prev(expr,i)</code>	Evaluate expression at the i th previous time step.	prev
<code>reacf(u)</code> <code>reacf(u,dim)</code>	Accurate evaluation of reaction forces and fluxes.	reacf
<code>realdot(a,b)</code>	Treat complex numbers a and b as real 2-vectors and return their dot product.	realdot
<code>residual(expr)</code>	Evaluate last computed residual.	residual
<code>scope.atent(i,ent,expr)</code>	Evaluates the expression $expr$ at an i -dimensional entity with number ent .	entity at
<code>scope.ati(coordinate exprs,expr)</code> <code>scope.ati(coordinate exprs,expr,'evaltype')</code>	Evaluates the expression $expr$ at an i -dimensional entity in the point with coordinates given by the coordinate expressions $coordinate\ exprs$.	spatial at
<code>sens(expr,i)</code>	Evaluate expression using the forward sensitivity for the parameter given by the second argument.	sens
<code>setconst(const,value)</code>	Define temporary constant in <code>withsol</code> .	setconst
<code>setind(par,index)</code> <code>setval(par,value)</code>	Specify parameter index or parameter value in <code>withsol</code> .	setind and setval
<code>shapeorder(variable)</code>	The element order used for discretization of a variable.	shapeorder
<code>side(entity,expr)</code>	Evaluate expression as defined in the adjacent entity.	side
<code>subst(expr,expr1_orig,expr1_subst,...)</code>	Substitute variables in an expression with other variables or expressions.	subst
<code>sum(expr,index,lower,upper)</code>	Evaluate sum of general expression for all indices from lower to upper.	sum
<code>test(expr)</code>	Test function operator.	test
<code>timeint, timeavg</code>	Integrate or compute the average of a time-dependent expression over a time interval.	timeint and timeavg
<code>timemax, timemin</code>	Evaluates the maximum or minimum of an expression over time.	timemax and timemin
<code>treatasconst(expr)</code>	Treat $expr$ as independent of the solution.	treatasconst
<code>try_catch(tryExpr, catchExpr)</code>	Attempts to evaluate $tryExpr$, but if this fails for any point, $catchExpr$ is evaluated instead.	try_catch
<code>uflux(u), dflux(u)</code>	Evaluate the flux associated to a dependent variable u into the domains on the up and down sides of a boundary, respectively.	Boundary Flux Operators: uflux and dflux
<code>up(expr)</code>	Evaluate expression as defined in adjacent upside.	up and down
<code>var(expr,fieldname1,fieldname2, ...)</code>	Variation operator.	var
<code>with</code>	Access specific solutions during results evaluation.	with
<code>withsol(tag,expr)</code>	Access solution defined by solver tag.	withsol

ADJ

- When you apply the adjoint sensitivity operator `adj` to an expression, COMSOL Multiphysics uses the adjoint sensitivity solution instead of the primal solution for the evaluation.
- The adjoint sensitivity solution is available for results when the sensitivity solver has been used with the adjoint sensitivity method, and for the dependent variables that have been solved for.

AT

- The `at` operator can access a solution to a time-dependent problem at any time. COMSOL Multiphysics provides the solution at that time using interpolation. You can use the `at` operator to compare two solutions at different times during results evaluation; for example, `at(30,u) - at(20,u)` is the difference between the solution at 30 s and the solution at 20 s.
- The first input argument is the time. The second input argument is the expression that you want to evaluate using this solution. For example, `at(12.5,u)` is the solution at 12.5 s. The time must be within the simulation time span but does not have to be a specified output time. If it is not, then the `at` operator uses interpolation to compute the data values at that time.
- You can also use '`first`' or '`last`' as the first argument to evaluate an expression at the first or last time of the simulation, respectively.
- The `at` operator can only be used during results evaluation, so it should not be used when setting up the model.

See also [withsol](#) for a more general operator.

ATLOCAL

- The `atlocal` operator takes 2, 3, or 4 arguments depending on the dimension of the geometrical entity it is being evaluated on.
- For example, on a three-dimensional entity, `atlocal(xi1,xi2,xi3,expr)` evaluates `expr` at the point with local coordinates (ξ_1, ξ_2, ξ_3) in each mesh element. On a two-dimensional entity the syntax is `atlocal(xi1,xi2,expr)` and on a one-dimensional entity it is `atlocal(xi1,expr)`.

ATTIMEMAX AND ATTIMEMIN

- The `attimemax` and `attimemin` operators evaluate an expression at the time where another expression achieves its maximum or minimum, respectively. `attimemax(t1,t2,expr1,expr2)` finds the time t_0 on the interval $t_1 \leq t \leq t_2$ where `expr1(t)` is maximal and computes `expr2(t_0)`. The first two arguments must be real constants.
- `attimemax(t1,t2,expr1,expr2,'nointerp')` and `attimemin(t1,t2,expr1,expr2,'nointerp')` evaluate the maximum or minimum without doing any interpolation between the stored time steps. This variant might be less accurate but faster and more robust.
- The `attimemax` and `attimemin` operators can only be used during results evaluation, so you cannot use them when setting up the model. See [timemax](#) and [timemin](#) for similar operators.

ATXD, ATONLY, AND NOXD

When working with extra dimensions, evaluation can be done in either a standard base geometry, in an extra dimension geometry, or in a product of a base geometry and one or several extra dimension geometries. The `atxd`, `atonly`, and `noxd` operators modify the evaluation context by adding or removing geometries from the current product.

All of these operators have a scope indicating the base geometry or extra dimension to which they belong. The scope for base geometries is typically `comp1`, `comp2`, and so on, while the scope for extra dimensions is typically `xdim1`, `xdim2`, and so on. Also, the `atxd` operators have a suffix 0, 1, 2, or 3, which indicates the dimension of the geometric entities where their argument is evaluated. So, the complete name of an `atxd` operator is, for example,

`xdim1.atxd2`, and the complete name of an `atonly` or `noxd` operator is, for example, `comp1.atonly` or `xdim1.noxd`.

The `atxd` operators add another geometry to the current product. Suppose, for example, that you have a 2D base geometry with scope `comp1`, and a 2D extra dimension geometry with scope `xdim1`. Starting in an evaluation context in the base geometry, `xdim1.atxd1(2,3,expr)` evaluates `expr` in the product of `comp1` and `xdim1`, at a point on the boundary in `xdim1` with coordinates (2, 3). Starting in an evaluation context in the extra dimension, `comp1.atxd2(4,5,expr)` evaluates `expr` in the product of `comp1` and `xdim1`, at a point in a domain in `comp1` with coordinates (4, 5).

When there is a product of a base geometry with more than one extra dimension, several nested `atxd` operators can be used to specify evaluation in the product. For example, suppose `xdim2` and `xdim3` are 1D extra dimensions attached to a base geometry `comp1`. Starting in the base geometry, `xdim2.atxd1(2,xdim3.atxd0(3,expr))` evaluates `expr` in the product of `comp1` with `xdim2` and `xdim3`. The order of applying the two operators is inconsequential.

The following points are worth noting about the `atxd` operators:

- The number of arguments is always `sdim+1`, where `sdim` is the dimension of the geometry indicated by the scope of the operator.
- The first `sdim` arguments specify coordinates in this geometry. They must be constant in the current evaluation context.
- The last argument is an expression that is evaluated in the product context specified by the operator.
- The operator name suffix is an integer i in the range $0 \leq i \leq sdim$.
- The product geometry specified by the operator must have been created using an Attached Dimensions feature in the model.

The `atonly` operators remove all but one geometries from the current product. Consider again the example where `comp1` is a base geometry and `xdim1` is an extra dimension. Starting in the product of `comp1` and `xdim1`, `comp1.atonly(expr)` evaluates `expr` in the base geometry, and `xdim1.atonly(expr)` evaluates `expr` in the extra dimension. `expr` must be available in the geometry corresponding to the `atonly` prefix (for example, in the base geometry for `comp1.atonly`).

The `noxd` operators are similar to the `atonly` operators, but instead remove a single geometry from the current product. This is most useful in products with more than one extra dimension, because in products with just one extra dimension, an `atonly` operator can be used instead. For example, in the product of a base geometry `comp1`, and extra dimensions `xdim2` and `xdim3`, `xdim2.noxd(expr)` evaluates `expr` in the product of `comp1` and `xdim3`.

BALL, CIRCLE, DISK, AND SPHERE

- The `ballint(r,expr)` operator computes the volume integral of the expression `expr` in a ball with radius r around the point in which it is evaluated. The `ballint` operator can be evaluated on all entities in 3D.
- The `ballavg(r,expr)` operator is defined as `ballint(r,expr)/ballint(r,1)`.
- The `circint(r,expr)` operator computes the curve integral of the expression `expr` on a circle with radius r around the point in which it is evaluated. The `circint` operator can be evaluated on all entities in 2D and on edges in 3D, when used in 3D the integration is done on the circle in the normal plane to the edge.
- The `circavg(r,expr)` operator is defined as `circint(r,expr)/circint(r,1)`.
- The `diskint(r,expr)` is similar to the `circint` operator but calculates the surface integral on a disk instead.
- The `diskavg(r,expr)` operator is defined as `diskint(r,expr)/diskint(r,1)`.
- The `sphint(r,expr)` is similar to the `ballint` operator but computes the surface integral on a sphere instead.
- The `sphavg(r,expr)` operator is defined as `sphint(r,expr)/sphint(r,1)`.

- All of operators can be used with a third argument N that approximately specifies the number of integration points used — for example, `circint(r, expr, 100)`.
- To all operators you can add a suffix (“`_frameId`”) that specifies the frame in which the integration is done — for example, `circint_spatial(r, expr)`.
- The expression `expr` may contain the `dest` operator. The `dest` operator forces its expression to be evaluated in the center of the sphere or circle. You can use it, for instance, with a `sphint` operator to write expressions including the sphere’s normal direction.

BDF

- Use the `bdf` operator to approximate time derivatives when the time discrete solver is used.
- The expression `bdf(expr, i)` results in a discretization of the time derivative of `expr` using a backward differentiation formula.
- The second argument, i , determines the order of accuracy of the discretization. Currently, first order and second order is available, so allowed values are $i = 1$ and $i = 2$. A second-order formula requires access to two previous time steps. Because this is not possible at the initial step, the evaluation at the initial step always uses the first-order formula.
- The `bdf` operator can be implemented using the `prev` operator. For example, obtain the first-order backward differentiation formula, also known as the backward Euler method, through `bdf(u, 1) = (u-prev(u, 1))/timestep`.

BOUNDARY FLUX OPERATORS: UFLUX AND DFLUX

- If you have selected **Compute boundary fluxes** in a physics interface defining a dependent variable u , `uflux(u)` and `dflux(u)`, when evaluated on a boundary, give an accurate value of the boundary flux into the domains on the up and down side of the boundary, respectively.
- If you have not selected **Compute boundary fluxes**, the `uflux` and `dflux` operators give a less accurate value of the flux into the domain, based on the gradient of u . The less accurate method is always used if the operators are evaluated during solution because accurate boundary fluxes are not available then.
- The flux for different frames can be obtained by appending `_material`, `_spatial`, `_mesh`, or `_geometry` to the operator names. The default is the material frame.

The `uflux` and `dflux` operators are only applicable to dependent variables defined by physics interfaces that support accurate boundary fluxes.

[Computing Accurate Fluxes](#)

CENTROID

- The `centroid(expr)` operator evaluates the expression `expr` in the centroid of the mesh element to which the point belongs.
- Note that the operator is context sensitive in the sense that it chooses the mesh element of the same dimension (a point often belongs to several different mesh elements) as the context in which the evaluation is performed.

CIRCUMCENTER

- The `circumcenter(expr)` operator evaluates the expression `expr` in the circumcenter of the mesh element to which the point belongs. This point is in general only well defined for simplices. For other mesh elements, a point with approximately the same distance to all vertices of the mesh element is computed.

- Note that the operator is context sensitive in the sense that it chooses the mesh element of the same dimension (a point often belongs to several different mesh elements) as the context in which the evaluation is performed.
- You can add a suffix (“`_frameId`”) that specifies the frame in which the evaluation is done — for example, `circumcenter_spatial(expr)`.

DIFFERENTIATION OPERATORS: D, PD, AND DTANG

- All differentiation operators (`d`, `pd`, and `dtang`) can be used both in model settings and in results evaluation.
- Use the `d` operator to differentiate a variable with respect to another variable, using the chain rule for dependent variables. For example, `d(T,x)` means differentiation of `T` with respect to `x`. Some space derivatives are also available using predefined variables. For example, `uxx`, `d(ux,x)`, and `d(d(u,x),x)` are equivalent for a dependent variable `u` when evaluated in a domain. On a boundary, however, `d(u,x)` is 0, while `ux` is the average of the values from the adjacent domains.
- The `pd` operator works in a similar way to the `d` operator. The main difference is that `pd(u,x)` is 0 rather than `ux` (no chain rule is applied for dependent variables).
- Use the `dtang` operator to compute derivatives in the tangential direction along a boundary. The `dtang` operator can be applied to expressions that are only defined on the boundary and therefore cannot be differentiated by the `d` operator. In a 3D model, `(dtang(f,x), dtang(f,y), dtang(f,z))` is a vector in the tangent plane of a boundary at the point where it is evaluated, and similarly in a 2D model, `(dtang(f,x), dtang(f,y))` is a vector in the tangent line of a boundary point. When evaluated in a domain, `dtang(f,x)` is the same as `d(f,x)`. The second argument of `dtang(f,x)` must be one of the spatial coordinates. Not all quantities have rules for evaluating tangential derivatives. Applying `dtang(f,x)` to an expression with no tangential derivative rule results in an error message.
- Time derivatives can be written as `d(u,t)` or `d(u,TIME)` depending on the context. If the model does not contain any ALE (arbitrary Lagrangian-Eulerian) formulation, always use `d(u,t)` (or `ut`). In the presence of ALE, `d(u,TIME)` computes the time derivative for fixed points in the mesh and is usually the best way to compute a time derivative because `d(u,t)` is not supported for many variables.

Examples of Using the Differentiation Operators

The expressions `d(u^2,u)` and `pd(u^2,u)` both equal `2*u`; `d` also takes the spatial and time variables into account and treats their derivatives accordingly. In other words, if `u` is the dependent variable and `x` and `t` are the spatial coordinate and time, respectively, then `d(u+x,x)` equals `ux+1` (`ux` is the spatial derivative of `u` with respect to `x`), while `pd(u+x,x)` equals 1 because `u` is considered to be independent of anything but itself in the case of `pd`. Equivalently, `d(u,t)` equals `ut`, while `pd(u,t)` is zero.

If a time-dependent model contains two dependent variables `u` and `v`, use `d(u*v,t)` to compute the derivative of the product `uv` with respect to time `t`. The `d` operator uses the chain rule and is equivalent to `u*vt+ut*v` (using COMSOL Multiphysics syntax). `pd(u*v,t)`, on the other hand, is zero.

If `u` is a dependent variable defined only on a boundary, `d(u,x)` is not defined, but the tangential derivative `dtang(u,x)` can be evaluated on the boundary. The tangential derivative obeys most of the common differentiation rules, such as the product rule and the chain rule; however, `dtang(x,x)` is not always equal to 1.

DEPENDS

- The `depends(expr)` operator returns 1 if the expression `expr` that it operates on depends on the solution; otherwise it returns 0.
- `depends(expr, var)` returns 1 if `expr` depends on `var`; otherwise it returns 0.

Use this operator to check user-defined expressions for dependency on the solution.

DEST

The `dest` (destination) operator is available for the following operators:

- Coupling operators: Integration, Maximum, Minimum, General Projection, Linear Projection, and Integration Over Extra Dimension.
- Built-in operators: `ballint`, `ballavg`, `circint`, `circavg`, `diskint`, `diskavg`, `sphint`, and `sphavg`.

The `dest` operator forces the expression that it operates on to be evaluated on the destination points instead of the source points. This means that the destination operator can be used to create convolution integrals and other integral transforms. For instance, integrating the expression `u/((dest(x)-x)^2+(dest(y)-y)^2)` gives the following function of `x` and `y`:

$$f(x, y) = \int \frac{u(x', y')}{(x - x')^2 + (y - y')^2} dx' dy'$$

The `dest` operator can also be used in the operator listed in the section [ball, circle, disk, and sphere](#). In this context, the forced point of evaluation is the center of the sphere or circle. You can use it, for instance, with a `sphint` operator to write expressions including the sphere's normal direction.

EMETRIC

The `emetric(vector)` returns the square of the length of a 2-vector computed in the mesh element's own covariant metric. In this metric, the edges of the mesh element typically have length 1, and vectors orthogonal to the element have length 0. The number of input arguments defining the vector should be equal to the space dimension. You can add a frame suffix to change from the default material frame to the frame that you want. For instance, you can write `emetric_spatial(vector)` to use the spatial frame.

If you are more interested in the contravariant element metric, its components can be accessed by the variables `emetricinvxx`, `emetricinvxy`, `emetricinvXX`, and so on. See also the entries for `emetric2` and `tremetric` in [Table 5-9](#) for related variables.

ENTITY AT

The `scope.atenti(ent, expr)` operator evaluates the expression `expr` in the geometry with the given scope (typically `comp1` for Component 1 or a similar scope for another Component branch) on the i -dimensional entity with number `ent`. The entity does not have to be meshed and not even be inside the geometry. Domains outside the geometry have nonpositive `dom` values.

The evaluation is performed without a mesh and that the expression thus cannot depend on the position within the entity. For a similar operator, use `scope.at3(coordinate exprs, expr, 'mi')`; see [spatial at](#).

ENV, BNDENV, AND NOENV

These operators can only be evaluated on particles or rays in a particle tracing or ray tracing simulation. Thus, the Particle Tracing Module, Ray Optics Module, or Acoustics Module is required.

- Evaluating `env(expr)` on a particle or ray evaluates `expr` at the point in the domain where the particle or ray is. When evaluating a variable `var` on a particle or ray, if the variable is not defined on the particle or ray it is automatically replaced by `env(var)`. Therefore the `env` operator can often be omitted.

- Evaluating `bndenv(expr)` on a particle or ray, evaluates `expr` at the point on the boundary where the particle or ray is. If the particle or ray is not on a boundary, the evaluation fails. Use this operator instead of `env` when evaluating expressions that are only defined on boundaries.
- The `noenv(expr)` operator can only be used as part of an expression within the `env(expr)` or `bndenv(expr)` operator. The `noenv(expr)` operator is used to evaluate an expression `expr` that is defined for particles or rays but is not defined at their locations within a domain or on a boundary. For example, if you write `env(expr1*noenv(expr2))`, then the `expr1` must be defined in the domain where the particle or ray is, and `expr2` must be a quantity that is defined for individual particles or rays, such as the particle speed.

ERROR

- The `error(string)` operator generates an error with error message `string`.
- You can for instance use this operator to make assertions on how your solution should behave. If you write `if(cond,expr,error('cond is false'))` `expr` is calculated when `cond` is true and an error message is generated including the text `cond is false`, when `cond` is false.

FSENS AND FSENSIMAG

- The functional sensitivity operator `fsens` evaluates the sensitivity of the current objective functional with respect to the control variable given as the single argument. Note that the argument must be a control variable name; other dependent variables or general expression are not allowed.
- The functional sensitivity operator `fsensimag` evaluates the sensitivity of the current objective functional with respect to the imaginary part of the control variable given as the single argument.
- The functional sensitivity is available for analysis when the sensitivity solver has been used with either the adjoint or the forward sensitivity method, and for the control variables that have been solved for.

For a complex-valued control variable $z = x + iy$, denote a sensitivity function f as

$$f = f(z) = u(z) + iv(z)$$

When you use complex splitting, you can think of the sensitivity as a matrix of derivatives

$$J = \begin{pmatrix} u_x & v_x \\ u_y & v_y \end{pmatrix}$$

In that case, `fsens` returns the first row, and `fsensimag` returns the second row as $v^y - iu_y$.

GPEVAL

The `gpeval` operator evaluates the expression in the specified Gauss point pattern and extrapolates the result to the input evaluation points, using the specified extrapolation order.

- `gpeval(gporder,expr)` evaluates the expression `expr` in the Gauss point pattern given by the Gauss point order (integration order — see [integration order](#) in the *Glossary*) in `gporder` (a positive integer). The value of `gporder` determines the points where `expr` is evaluated. Extrapolation (see below) is in this case done using an `exorder` set to 1.
- `gpeval(gporder,expr,exorder)` uses an optional extrapolation order `exorder`. The extrapolation order is an integer larger or equal to -1. -1 gives the maximum order given the value of `gporder`; the order used is limited by the number of Gauss points used. The extrapolation tries to create a polynomial approximation of expressions that are based on positions and values evaluated in the Gauss points. The order of such polynomials (`exorder`) cannot be arbitrarily high — the number of evaluation points limits the order of the polynomials.

IF

- The `if(cond,expr1,expr2)` operator implements a conditional expression.
- The first argument is a condition that COMSOL Multiphysics treats as a Boolean expression. If — at a particular evaluation point — `cond` is true, then the second argument is evaluated, otherwise the third argument is evaluated. That is, only one branch is evaluated at any evaluation point.
- Use the `if` operator to avoid illegal operations. For example, `if(x==0,1,sin(x)/x)` is a valid and continuous expression for all values of x , including $x = 0$.

See also [nif](#) for a nested conditional expression.

INTEGRATE

- `integrate(expr,var,lower,upper)` computes the integral of `expr` for the integration variable `var` over an interval specified by expressions `lower` for the lower limit and `upper` for the upper limit. The expressions for lower and upper limits do not have to be constants but are required to evaluate to real values.
- `integrate(expr,var,lower,upper,tol)` sets the relative tolerance in the numerical integration to `tol`. The default value of the relative tolerance (used when the fifth argument is omitted) is `1e-3`. The tolerance must be a real constant between 0 and 1.
- The expression `expr` might be any 1D function, such as `sin(x)`. It is also possible to include additional variables, such as `sin(xy)`. The second argument specifies over which variable the integral is calculated. For example, `integrate(sin(x*y),y,0,1)` yields a function of x , because integration only eliminates the integration variable y . Note that the operator can also handle analytic functions, which you define under **Definitions** in the current component.
- It is possible to use a coordinate name as the integration variable in the `integrate` operator. Note, however, that this will not change the evaluation point where the first argument is evaluated. For example, if u is a dependent variable, `integrate(u,x,a,b)` is equivalent to `u*integrate(1,x,a,b)`.
- To evaluate an integral over a geometrical curve, the `integrate` operator can be combined with one of the *spatial at* operators. For example, in a 2D model, `integrate(comp1.at2(x,y,u),x,a,b)` will integrate u along the line segment with endpoints (a,y) and (b,y) .

ISINF AND ISNAN

- The `isinf` operator returns 1 if the expression that it operates on evaluates to infinity (or minus infinity); otherwise it returns 0.
- The `isnan` operator returns 1 if the expression that it operates on evaluates to NaN (not-a-number); otherwise it returns 0.

ISLINEAR

- The `islinear` operator returns 1 if the expression that it operates on is a linear function of the solution; otherwise it returns 0.
- Use this operator to check user-defined expressions for linearity with respect to the solution. The stationary solver does this automatically to choose between a linear or a nonlinear solver.

JACDEPENDS

- The `jacdepends(expr)` operator returns 1 if the derivative of the expression `expr`, with respect to any part of the solution, depends on the solution; otherwise it returns 0.
- `jacdepends(expr,var)` returns 1 if the derivative of the expression `expr`, with respect to any part of the solution, depends on `var`; otherwise it returns 0.

LINDEV

The `lindev` operator evaluates its argument in the following way when the solution has a stored linearization point: The expression is first linearized at the linearization point and then evaluated at the current solution. In particular, if f depends linearly on the solution, `lindev(f)` is the same as f . If f does not depend on the solution, `lindev(f)` is 0. If the solution does not have a stored linearization point, `lindev` linearizes around zero.

LINPER

The `linper` operator has one single use: To indicate load terms that should be used by stationary solvers setting **Linearity** to **Linear perturbation** in the **Settings** window for **Stationary Solver**. Terms not enclosed by `linper` are ignored by such solvers. On the other hand, terms inside `linper` are ignored by all other solvers.

LINPOINT

The `linpoint` operator can access the linearization point in a solution with a stored linearization point. If the solution does not have a stored linearization point, using `linpoint` causes an error message.

LINSOL

The `linsol` operator evaluates an expression using the standard solution. This is the default, so in most contexts the operator is not very useful. However, it can, for example, be used inside the argument of `linpoint` to evaluate a part of the expression with the standard solution instead of the linearization point.

LINTOTAL

The `lintotal` operator can access the sum of the linearization point and the linear perturbation in a solution with a stored linearization point. If the solution does not have a stored linearization point, using `lintotal` causes an error message.

LINTOTALAVG

The `lintotalavg` operator evaluates the average of an expression over all phases. `lintotalavg(f)` is evaluated by taking the average of `lintotal(f)` with the solution (but not the linearization point) multiplied by $e^{i\varphi}$ for a number of phases φ . The number of phases is automatically selected to achieve an accurate value.

`lintotalavg(f,n)` uses n equidistantly spaced phases.

LINTOTALPEAK

The `lintotalpeak` operator evaluates the maximum of an expression over all phases. `lintotalpeak(f)` is evaluated by taking the maximum of `real(lintotal(f))` with the solution (but not the linearization point) multiplied by $e^{i\varphi}$ for a number of phases φ . The number of phases is automatically selected to achieve an accurate value. `lintotalpeak(f,n)` uses n equidistantly spaced phases.

LINTOTALRMS

The `lintotalrms` operator evaluates the RMS of an expression over all phases. `lintotalrms(f)` is the same as `sqrt(lintotalavg(abs(f)^2))`.

LINZERO

The `linzero` operator evaluates an expression using a zero solution. This is mostly used internally in the definitions of some other operators.

MEAN

- The COMSOL Multiphysics software can evaluate expressions on entities of different dimensions and this might affect the result. For instance, a point can lie on an edge, which can be an edge of a square, which can be part of the boundary of a cube. If you now want to access the numbering of the entity it is obvious that you should get different results for the point, edge, square and cube. If on the other hand you want to know the value of the dependent variable, this should be the same if you think of the point as part of a point, edge, square, or cube.

- The `mean` operator can be called on any entity that has a lower dimension than the model. The dimension of the entity from where the call is made is called `n`.
- The `mean` operator determines the smallest integer `m>n` for which there are adjacent entities of dimension `m`. It then evaluates the expression at the point one time for each `m` dimensional adjacent entity, regarding the point as a point in the entity, and takes the average of the calculated values.

See also [up](#) and [down](#) and [side](#) for similar operators.

NIF

- The `nif(cond1,expr1,...,condn,exprn,exprn+1)` operator implements a nested conditional expression. It can be transcribed as “if `cond1`, then `expr1`, else if ..., else if `condn`, then `exprn`, else `exprn+1`”.
- The `nif` operator can have any odd number of arguments greater than or equal to 3.
- `cond` is considered true if nonzero.
- `nif(cond1,expr1,expr2)=if(cond1,expr1,expr2)`

See also [if](#).

NOJAC

- The `nojac` operator makes sure that any expression that it operates on is excluded from the Jacobian computation (it prevents all symbolic differentiation). This is useful if a Jacobian contribution is not strictly necessary and the computational requirements for it are high, such as when using a nonlocal coupling. The use of the `nojac` operator can then significantly lower the memory requirements by avoiding fill-in of the Jacobian matrix, but its use might also slow down the convergence of the solution.
- The *k-e* turbulence model is an example where a built-in use of the `nojac` operator improves performance.

PPR AND PPRINT

- When the `ppr` operator is applied on an expression, the COMSOL Multiphysics software uses *polynomial-preserving recovery* to evaluate all variables in the expression that are discretized using Lagrange shape functions. For example, if `e = ux + vy`, then `ppr(e^2)=(ppr(ux)+ppr(vy))^2`. For other shape function types, the operator has no effect.

Polynomial-Preserving Derivative Recovery

- The `pprint` operator similarly applies polynomial-preserving recovery within each group of domains with equal settings. Use these operators to get an estimate of the discretization error in the gradient. For example, `ux-pprint(ux)` in a 1D model.

If these operators are applied on expressions that are used when solving the model, COMSOL Multiphysics computes the Jacobian approximately by ignoring the operator. For example, the Jacobian of `ux-pprint(ux)` is 0.

PREV

When the time discrete solver is used, it stores the solution at a number of previous time steps.

- The expression `prev(expr,i)` evaluates `expr` using the solution obtained `i` time steps before the current time step.
- The operator can be used in equations as well as for results evaluation.

- When used in equations, the `prev` operator makes it possible to discretize time derivatives. For example, to discretize ut (the time derivative of u) with the formula known as the *backward Euler method*, use the expression $(u-prev(u,1))/timestep$. Here, `timestep` is the size of the time step used to reach the current solution u . The `prev` operator is also applicable for `timestep`. For example, `prev(timestep,1)` is the size of the time step used to reach the solution at the previous time step.
- When using the `prev` operator, sufficiently many previous time steps must be stored. Specify the number of previous time steps to store in the time discrete solver (time discrete levels) in the **Number of time discrete levels** field in the **General** section of the **Settings** window for **Time Discrete Solver**. Evaluating an expression at a previous time step that has not been stored results in an error.

REACF

The reaction force operator (`reacf`) evaluates the reaction force at each node point where a constraint is applied. The reaction force at a node is equal to the corresponding component of the negated residual vector $-L$ computed while solving the model. The reaction forces are stored together with the solution vector by the solvers.

- The reaction force operator (`reacf`) is useful when calculating integrals of reaction forces or fluxes.
- Apply the `reacf` operator on the names of dependent variables when doing a surface integration. For example, in structural mechanics, with dependent variables u and v corresponding to x - and y -displacements, use `reacf(u)` and `reacf(v)` to access integrals of the reaction forces in the x - and y -direction, respectively. The integration for the reaction force is a summation over the nodes, so the integration method must be summation rather than integration. The automatic integration method in the integrations available under **Results>Derived Values** detects the use of the `reacf` operation and then uses the summation method.
- If you integrate the reaction force separately over two adjacent constrained boundaries, the sum of the two results is in general not equal to what you get if you perform the integration over both boundaries in one operation. The nodes that are shared between the two boundaries are included in both integrations. Another way of stating this is that the reaction force in a node has contributions from all elements attached to the node, so there is some influence also from the closest elements on a neighboring boundary. This discrepancy decreases if you refine the mesh because the reaction force on a node is proportional to the element size. See also [Computing Accurate Fluxes](#).
- Storing of the reaction forces can be disabled by clearing the **Reaction forces** check box in the **Output** section in the solver's **Settings** window. This saves some computational time and memory. It is then not possible to use the reaction force operator.
- You can call `reacf` with an optional second argument. The second argument is the dimension of the entity where the reaction force should be evaluated. The dimension is assumed to be at least equal to the dimension from where the call to `reacf` is made. This is different from `reacf(u)` only in the case when u is not defined on the entity where the operator is evaluated but only on adjacent entities of higher dimension.
- It is also possible to call `reacf` with an optional third argument. This is a factor that the COMSOL Multiphysics software multiplies `reacf(u,dim)` by. The third argument is evaluated on each adjacent entity of dimension `dim` and multiplied by the reaction forces on that entity.
- When using weak constraints, the residual vector is always 0, so reaction forces are not available.

REALDOT

- The expression `realdot(a,b)` treats complex numbers a and b as if they were real-valued vectors of length 2 and returns their dot product. Also think of the operator call as a shorthand form of `real(a*conj(b))`. This expression, however, is not an analytical function of its complex arguments and therefore has no unique partial derivatives with respect to a and b .

- The difference between `realdot(a,b)` and `real(a*conj(b))` is that the partial derivatives of the former with respect to a and b are defined as $\text{conj}(b)$ and $\text{conj}(a)$, respectively, while for the latter expression, the partial derivatives are $\text{real}(b)$ and $\text{real}(a)$.

The difference between the partial derivative definitions is important during sensitivity analysis of frequency-response problems (scalar or vector Helmholtz equations).

- Common objective function quantities like power and energy must be redefined in terms of `realdot(a,b)` rather than `real(a*conj(b))` for the sensitivity solver to compute correct derivatives. This applies also to the absolute value, `abs(a)`, via the definition $|a|^2 = \text{realdot}(a, a)$.
- The `realdot` function is nonanalytic, and it is therefore not possible to express and evaluate the Jacobian of that function correctly when a complex-valued solution vector is represented in terms of single complex-valued degrees of freedom. For that reason, the `realdot` operator, by default, results in Jacobian contributions during assembling only when the **Split complex variables in real and imaginary parts** settings in the **Compile Equations** node for the Study is active. The default behavior of Jacobian contributions is possible to override by providing an optional third argument to `realdot`:

```
realdot(a,b,jaclevel)
```

The `jaclevel` argument controls Jacobian contributions of the `realdot(a,b)` operator and can have the following values:

- 1: (default) Jacobian contributions in the assembling only if splitting of complex variables in real and imaginary part is active for the Study.
- 0: no Jacobian contributions
- 1: always Jacobian contributions

RESIDUAL

- To access the latest assembled residual, use the `residual` operator. For example, you can plot `residual(spf.U)` to get a plot of the latest residual of the velocity U in a fluid-flow simulation. The residual can provide insight into convergence issues by showing the locations where the algebraic residual is large.
- The computation of the residual uses an update scheme where, in each iteration, the solver computes the residual, updates the stored residual vector, and then computes the Jacobians.
- To make the residual available in the simulation output (for plotting, for example), specify that the solver stores it both while solving and in the output by selecting **While solving and in output** from the **Store last residual** list in the **Advanced** solver node's **Settings** window.
- For interpolated output (the **Times to store** list set to **Specified values**), no data is stored for the residual (NaN).

SENS

- When the forward sensitivity operator (`sens` operator) is applied to an expression, COMSOL Multiphysics uses the forward sensitivity solution with respect to the indicated control variable instead of the primal solution for the evaluation. This means, in practice, that when the first argument is a linear expression in the dependent variables, the operator returns its derivative with respect to the control variable given as second argument. The result for a nonlinear expression usually lacks meaning.
- The forward sensitivity solution is available for analysis when the sensitivity solver has been used with the forward sensitivity method, and for the dependent variables and control variables that have been solved for.

- For scalar control variables, access the corresponding forward sensitivity solution by giving the control variable name as the second argument to this operator. For example, with the dependent variable u and the scalar control parameter q , access the forward sensitivity solution $\partial u / \partial q$ as `sens(u,q)`.
- For a control variable field, which is not a scalar, a more elaborate syntax specifying a unique degree of freedom must be used. This is done by giving an integer as the second argument, corresponding to the global degree of freedom number for the requested control variable degree of freedom. The degree of freedom index for the sensitivity parameter must be a number greater than or equal to 1.

SETCONST

Use the operator `setconst` to define temporary constants while the second argument of the `withsol` operator (see [withsol](#)) is evaluated. For example, `withsol('sol1',expr, setconst(a,3))` defines the variable `a` to have the value 3 while `expr` is evaluated. The `setconst` operator can be combined with `setind` or `setval` (see below) and does not affect the solution that is selected for evaluation.

You can use `setconst` with more than two arguments to make the syntax more compact. For example, `withsol('sol1',expr, setconst(a,3,b,4))` is equivalent to `withsol('sol1',expr, setconst(a,3), setconst(b,4))`.

SETIND AND SETVAL

Use `setind` to specify a parameter index and `setval` to specify a parameter value in connection with the `withsol` operator (see [withsol](#)). For parametric sweeps over several parameters, say `p` and `q`, `setval` and `setind` can be used in any combination for the two parameters — for example, `withsol('sol1',expr, setind(p,2,q,3))` or `withsol('sol1',expr, setind(p,2), setval(q,5))`.

Negative indices in `setind` are counted from the end. For example, in a time-dependent solver, `withsol('sol1',expr, setind(t,-2))` evaluates `expr` at the second last time step. An alternative notation for the first and last indices is `setind(p,'first')` and `setind(p,'last')`.

You can use `setind` and `setval` with more than two arguments to make the syntax more compact. For example, `withsol('sol1',expr, setval(p,1,q,2))` is equivalent to `withsol('sol1',expr, setval(p,1), setval(q,2))`.

SHAPEORDER

- The expression `shapeorder(u)` gives the element order used for discretization of the variable u .
- The argument u must be a dependent variable or a partial derivative of a dependent variable. In the latter case, the order returned is the order of the dependent variable itself and not the order of its derivative.
- It is an error to apply the `shapeorder` operator to, for example, an expression, a constant, or a spatial coordinate.

SIDE

- The COMSOL Multiphysics software can evaluate expressions on entities of different dimensions and this might not affect the result. For instance, a point can lie on an edge, which can be an edge of a square, which can be part of the boundary of a cube. If you now want to access the numbering of the entity it is obvious that you should get different results for the point, edge, square, and cube. If you, on the other hand, want to know the value of the dependent variable, this should be the same if you think of the point as part of a point, edge, square, or cube.
- The `side` operator can be called on an entity that has lower dimension than the model. The dimension of the entity from where the call is made is called `n`.

- The `side` operator is an operator that evaluates an expression, not on the entity where it is called but instead on one of the adjacent entities of dimension $n+1$. You choose which entity by giving its number (this is the number displayed, for instance, in the selection fields) as the first argument to the operator.
- It can happen that the entity you choose is adjacent to the evaluation point more than once. For instance, a boundary can have the same domain on both sides. In such cases the `side` operator takes the average of the different values.

See also [up](#) and [down](#) and [mean](#) for similar operators.

S P A T I A L A T

The operator evaluates an expression `expr` in a specific point in space. Typically, use `ati` without extra arguments when evaluating inside a mesh and add extra arguments when evaluating outside the mesh or even outside the geometry.

- The `scope.ati(<coordinate expressions>, expr)` operator evaluates the expression `expr` in the geometry with the given scope (typically `comp1` for Component 1 or a similar scope for another Component branch) on an *i*-dimensional entity in the point given by the coordinate expressions (`at0` for a 0-dimensional entity, `at1` for a 1-dimensional entity, `at2` for a 2-dimensional entity, and `at3` for a 3-dimensional entity). For example, `comp1.at1(0,y,dom)` evaluates `dom` in the two-dimensional geometry on an edge in the point $(0, y)$. To use a certain `ati` operator variant, there must be a meshed geometric entity of the right dimension at the coordinates where it is evaluated; for example, `at0` only works if the source geometry has a vertex in the point where you want to evaluate the expression. The number of arguments for the `scope.ati` operator is equal to the space dimension in the source component (the coordinate expressions) plus one (the expression to evaluate).
- For two- and three-dimensional models, the evaluation on the domain level (that is, `at2` for two-dimensional models and `at3` for three-dimensional models) can take an extra argument '`evaltype`'. The supported '`evaltype`' values are '`mi`' and '`minc`'. Contrary to regular `ati` evaluations, these evaluation types do not require any domain meshes and can be evaluated in any given point. However, if there are two adjacent domains for which something is defined differently, the operator requires that the boundary between the domains is meshed. The '`mi`' (mesh-independent evaluation) value checks that you have meshed all such required boundaries (even for variables that have nothing to do with the actual argument of the operator), whereas the '`minc`' (mesh-independent no-check evaluation) value does not, and it might therefore give inaccurate results if not used correctly.
- To all operators you can add a suffix ("`_frameId`") that specifies the frame in which the coordinate expressions are used — for example, `at1_spatial(x,y,expr)`. Without a suffix, the evaluation is performed in the material frame.

S U B S T

- The `subst` operator takes a variable or expression as its first argument, followed by one or more argument pairs, each consisting of a variable name and an expression. The first argument in each pair is an original variable that appears in the variable or expression that you specify as the first argument, and the second argument in each pair is the variable or expression that you want to substitute the original variable with. This can be useful, for example, for replacing the variable for temperature in a temperature-dependent expression for some quantity by a fixed initial temperature for use as an initial condition.
- As an example, the expression `subst(hmnf.nutildeinit,p, pin_stat)` (taken from the Sajben Diffuser model in the CFD Module's application library) substitutes the dependent variable for pressure, `p`, with a user-defined variable `pin_stat` for the inlet static pressure. The evaluation of the variable `hmnf.nutildeinit` (for the undamped turbulent kinematic viscosity) then takes the value of `pin_stat` instead of `p`.
- The unit of the output from the `subst` operator is the same as the unit for its first input argument.

SUM

The `sum` operator, when used as `sum(expr, index, lower, upper)`, is a summation operator that computes the sum of the terms `expr` for all `index` values from `lower` to `upper`. The expressions for lower and upper limits are required to evaluate to real values and to be independent of the evaluation point. For example, `sum(i^2, i, 1, 4) = 1^2+2^2+3^2+4^2 = 30.`

TEST

- The `test` operator is available for modeling using the weak formulation of the equations.
- This operator creates the test function for the variable that it operates on. For example, write `ux*test(u)` to represent u_x times the test function of u .

TIMEINT AND TIMEAVG

- The `timeint` and `timeavg` operators integrate and compute the average of a time-dependent expression over a time interval, respectively. `timeint(t1, t2, expr)` and `timeavg(t1, t2, expr)` compute the integral and average of `expr` over the interval $t=t_1$ to $t=t_2$, respectively. The first two arguments must be real scalars. The integral is computed by numerical integration, subdividing the interval until the required accuracy is reached. The `timeavg` operator numerically integrates the expression in the same way as `timeint` and then divides the result by t_2-t_1 .
- `timeint(t1, t2, expr, tol)` and `timeavg(t1, t2, expr, tol)` set the relative tolerance in the numerical integration procedure to `tol`. The tolerance must be a positive real constant. The default tolerance (used when the fourth argument is omitted) is `1e-8`.
- `timeint(t1, t2, expr, tol, minlen)` and `timeavg(t1, t2, expr, tol, minlen)` set the smallest length of the subintervals used in numerical integration as a fraction of the length of the whole integration interval. Subintervals smaller than this length are not further subdivided even if that means that the required accuracy is not reached. `minlen` must be a positive real constant. The default value of `minlen` (used when the last argument is omitted) is `1e-4`.
- `timeint(t1, t2, expr, 'nointerp')` and `timeavg(t1, t2, expr, 'nointerp')` evaluate the time integral without doing any interpolation between the stored time steps. This variant might be less accurate but faster and more robust.
- The `timeint` and `timeavg` operators can only be used during results evaluation, so you cannot use them when setting up the model.

TIMEMAX AND TIMEMIN

- The `timemax` and `timemin` operators evaluate the maximum and minimum, respectively, of an expression over time. `timemax(t1, t2, expr)` finds the maximum of `expr` on the interval $t_1 \leq t \leq t_2$. The first two arguments must be real constants.
- `timemax(t1, t2, expr, 'nointerp')` and `timemin(t1, t2, expr, 'nointerp')` evaluate the maximum or minimum without doing any interpolation between the stored time steps. This variant might be less accurate but faster and more robust.
- The `timemax` and `timemin` operators can only be used during results evaluation, so you cannot use them when setting up the model. See [attimemax](#) and [attimemin](#) for similar operators.

TREATASCONST

When deciding if a linear solver can be used, the `treatasconst(expr)` operator treats `expr` as independent of the solution (even if this is actually not the case).

TRY_CATCH

- The `tryCatch(tryExpr, catchExpr)` operator attempts to evaluate the expression `tryExpr`, but if this fails for any point, the operator evaluates `catchExpr` instead.
- Note that the result might depend on how the mesh elements are partitioned into blocks during evaluation, which can be rather arbitrary. As soon as evaluation of the first argument fails in some part of the block, the second argument gets evaluated in the entire block. Also, during postprocessing the behavior might change because NaN (Not-a-Number) values in a subset of the evaluation points are then accepted, so then the second argument's expression might not be evaluated even at points where the first argument fails.
- Consider using the `if` operator (see [if](#)) with a suitable condition as the first argument instead of the `tryCatch` operator, if the `if` operator is applicable.

UP AND DOWN

- The COMSOL Multiphysics software can evaluate expressions on both sides of a boundary. One way to do this is by using the `up` and `down` operators. These operators are available only on boundaries (that is, geometric entities of dimension one less than the dimension of the model).
- For an expression or a variable that is discontinuous across a boundary, the value is different on either side, and COMSOL Multiphysics normally displays the mean values on the boundary.
- Use the `up` and `down` operators to evaluate an expression on the upside or downside of the boundary. If the upside or downside is outside of the geometry, or if the variables in the expression are not active on that side, the `up` or `down` operator returns 0.

For more information about the upside and downside of a boundary, see [Tangent and Normal Variables](#). See also [side](#) and [mean](#) for similar operators.

VAR

- The `var` operator (variation operator) is available for modeling using the weak formulation of the equations.
- The `var` operator has the same function as the `test` operator but is limited to the specified set of fields.
- This operator creates the test function for the variable that it operates on. For an expression, such as `var(F(u, ∇u, v, ∇v), a)`, where the dependent variable `u` is in the field named `a` and the dependent variable `v` is not, the `var` operator is equivalent to:

$$\sum_i \text{test}(u_i) \frac{\partial}{\partial u_i} F(u_i, \nabla u_i, v_i, \nabla v_i) + \text{test}(\nabla u_i) \frac{\partial}{\partial \nabla u_i} F(u_i, \nabla u_i, v_i, \nabla v_i)$$

for all dependent variables u_i .

WITH

- The `with` operator can access specific solutions during results evaluation.
- For time-dependent problems, parametric problems, and eigenvalue problems, this makes it possible to use the solution at any of the time steps, any parameter value, or any eigensolution in an expression used for plotting or data evaluation. To evaluate a sum (average) of displacement for the first six eigenmodes above the rigid-body modes in a 3D solid mechanics model, for example, use `sum(with(m, (1/(m+1))*solid.disp), m, 7, 12)`, where `m` is the summation index, summing the displacements, divided by `m+1` to form the average, from eigenmode 7 to eigenmode 12.
- Use the solution number as the first input argument. The second input argument is the expression that you want to evaluate using this solution. For example, `with(3, u^2)` provides the square of the third eigensolution for an eigenvalue problem.
- You can also use '`first`' or '`last`' as the first argument to evaluate an expression at the first or last time of the simulation, respectively.

- For example, you can use the `with` operator to verify that two eigensolutions are orthogonal or to compare two solutions at different time steps or parameter values.
- If you want to use the `with` operator for a parametric problem, you should use a Parametric solver instead of a Parametric Sweep.
- The `with` operator can only be used during results evaluation, so you cannot use it when setting up the model.

See also [withsol](#) for a more general operator.

WITHSOL

The `withsol` operator can access the solution from any solver sequence in the current model. It can be used as soon as the solution has been computed. The first argument is the tag of the solver sequence, and the second argument is an expression to evaluate using that solution. Additional arguments can be added to specify the time step, eigenvalue, or parameter value. See also [setind](#) and [setval](#).

The `withsol` operator is similar to the `with` and `at` operators but is more general because it can access any solution in the current model.

Examples:

- `withsol('sol1',expr)` evaluates `expr` using the solution from the solver sequence with tag `sol1`.
- For a time-dependent solver, `withsol('sol1',expr)` evaluates at the last stored time step in the solution. Other time steps can be specified by using the `setind` or `setval` operators as additional arguments. For example, `withsol('sol1',expr,setval(t,0.5))` evaluates at the time step $t = 0.5$ (using interpolation between stored time steps if necessary), and `withsol('sol1',expr,setind(t,3))` evaluates at the third stored time step.
- For an eigenvalue solver, `withsol('sol1',expr)` evaluates at the first eigenvalue. Other eigenvalues can be specified using the `setind` operator as an additional argument. For example, `withsol('sol1',expr,setind(lambda,2))` evaluates at the second eigenvalue. (The `setval` operator can also be used with eigenvalues, but this is not very useful because the exact eigenvalues must then be known.)
- For a parametric sweep over a parameter `p`, `withsol('sol1',expr)` evaluates at the last parameter value. You can specify other parameter values using the `setind` or `setval` operators as additional arguments. For example, `withsol('sol1',expr,setval(p,4))` evaluates with the parameter value `p = 4`. `withsol('sol1',expr,setind(p,2))` evaluates for the second value of parameter `p`.
- To access a load case, use `setval`. For example: `withsol('sol2',truss.Sn,setval(loadcase,1))`.

Predefined and Built-In Variables

This section provides information about available predefined and built-in variables that represent properties of the physics, geometry, mesh, and other parts of the model, including some tips on how you can use them in models.

Predefined Physics Variables

Physics variables are predefined variables that the physics interfaces introduce. They are typically functions of the dependent variables and their derivatives. Many of these variables are available in the **Predefined quantities** lists in the settings for plots and other results nodes.

To access physics variables, use a variable scoping syntax that uses the **Name** to indicate the physics that they belong to.

The **Equation View** subnode is available for all physics nodes and contains a table with the names, expressions, units, and descriptions for the physics variables that the node defines. To display the **Equation View** subnodes, click the **Show** button () and select **Equation View** from the **Model Builder**.

Variable Naming Convention and Namespace

COMSOL Multiphysics uses a namespace with a hierarchical structure to control the access to variables within a model component and variables in other components within the same model. To access variables, use the following namespace syntax:

- To refer to the top level of the model tree, use `root`.
- To refer to variables in a Component branch, use its component name, such as `comp1`.
- To refer to variables in a physics interface, use its name such as `solid`.
- To refer to material properties, use the material node's name, such as `mat1`, and the name of the property group for the material property group, which is typically `def` for the Basic property group. For example, to access the density `p` in Material 1 use `mat1.def.rho` (or, using the full name for Component 1, `root.comp1.mat1.def.rho`; see below). Use this pattern when referencing other material properties too.
- The COMSOL Multiphysics software evaluates the physics variables in the model component's namespace, so you need to prepend the Name to access these variables. For example, `solid.disp` refers to the total displacement in a Solid Mechanics interface with the name `solid`.
- The dependent variables (field variables) are unique within a model, and you do not need the Name to access them. For example, enter `T` to access the temperature in a Heat Transfer interface using the default name for the temperature.
- When referring to a variable you only need to provide the part of the full name that makes the variable unique. For example, within a Solid Mechanics interface `solid` in Component 1 `comp1`, it is sufficient to type `solid.disp`, but `comp1.solid.disp` and the full name `root.comp1.solid.disp` are also correct. To access the same variable from another Component or from a Study, use `comp1.solid.disp` or `root.comp1.solid.disp`. The same mechanism applies to variables defined within a component. To access a global parameter `param1`, you can use `param1` directly or `root.param1`.

These variable naming conventions mean that the syntax becomes shorter when defining variables locally in a Component branch instead of globally. For example, to access the x -component of the electric field, E_x , in an

Electrostatics interface with the name `es` in a Component 1 with the name `comp1`, you can use `es.Ex` in a variable defined in Component 1, but for a variable defined globally, the syntax is `comp1.es.Ex`.

Variable Classification and Geometric Scope

COMSOL Multiphysics provides a set of variables that you can use in expressions when specifying a model and for visualizing and analyzing the solution. A number of variables are common to all physics interfaces in a Component, for example, the spatial coordinate variables x , y , and z (for 3D and planar 1D and 2D geometries).

Every physics interface also has its own set of variables to represent quantities relevant to the physics or equations that it covers. Characteristics of variables include:

- Parameters and geometric variables are always available.
- The choice of physics interfaces and the dimension of the geometries in the model affect the set of available field variables and special variables.
- Equations can be active in different domains, which also affects the set of available variables. Variables corresponding to certain equation terms are available only in the particular part of the geometry (such as domains, boundaries, or points) where the equation is active.
- Variables defined on boundaries, edges, and points are active if the adjacent domain is active.

Variables are divided into the following general categories:

- User-defined (local) *variables*
- [Built-In Global Variables](#)
- [Physical Constants](#) (predefined universal constants)
- [Geometric Variables, Mesh Variables, and Variables Created by Frames](#) (variables that characterize geometric properties).
- [Field variables](#) (dependent variables and variables derived from them). For example, [Shape Function Variables](#) and [Predefined Physics Variables](#).
- [Component Couplings and Coupling Operators](#)
- [Solver Variables](#) (available only during the solution process)

Built-In Global Variables

The following variables represent time (`t`), frequency (`freq`), eigenvalue (`lambda`), phase angle (`phase`), and the number of degrees of freedom (`numberofdofs`).

THE TIME VARIABLE

- For time-dependent problems, use the time variable (`t`) with the unit seconds (`s`).
- It can be part of any expression in the point, edge, boundary, and domain settings, as well as during analysis.
- It is always scalar, even when the solution contains more than one output time.
- For stationary models, the value of `t` is 0.
- The value of `t` for results evaluation corresponds to the selection made in the **Time** list in the **Data** sections for the visualization and data evaluation nodes in the **Results** branch in the **Model Builder**. See the [Results Analysis and Plots](#) section.

THE FREQUENCY VARIABLE

The frequency variable (`freq`) is the global frequency for models in the frequency domain (time-harmonic models and frequency response analysis, for example).

THE EIGENVALUE VARIABLE

- When specifying an eigenvalue problem, use the eigenvalue variable (`lambda`) like any other variable.
- The eigenvalue solver extracts the Jacobian, the damping matrix, and the mass matrix through Taylor expansion of the problem with respect to the eigenvalue variable around a specified eigenvalue linearization point (which is zero by default).
- Other solvers treat the eigenvalue variable as a constant with value zero, unless it is set by an eigenvalue solution used as initial solution.
- After solving an eigenvalue problem, the eigenvalue name is available as a scalar variable for use in expressions.
- To choose between different eigenvalues, select one from the **Eigenvalue** list in the **Data** sections for the visualization and data evaluation nodes in the **Results** section of the **Model Builder**. The value of the eigenvalue variable corresponds to the selection made in the **Eigenvalue** list. See the [Results Analysis and Plots](#) section.
- For many physics interfaces, the default is to use an eigenfrequency study and compute and display the eigenfrequencies rather than the eigenvalues.

THE PHASE ANGLE VARIABLE

The phase angle variable (`phase`) is the phase angle (in radians), primarily for postprocessing of models in the frequency domain, and you can specify its value in the **Settings** window for a data set, using the **Solution at angle (phase)** field. The default value is 0.

By default, the COMSOL Multiphysics software plots the real part of complex-valued data. You can use the `imag` function to plot the imaginary part and the `abs` function to plot the absolute value (modulus) of complex-valued data.

THE NUMBER OF DEGREES OF FREEDOM VARIABLE

The variable `numberofdofs` returns the total number of degrees of freedom (DOFs), which is the number of DOFs solved for plus any internal DOFs that the solver might add. The number of DOFs solved for plus the number of internal DOFs are reported in the **Messages** window when you compute the solution. COMSOL Multiphysics sometimes uses internal DOFs for storing information during solution that would be expensive or impossible to recompute afterward. Internal DOFs have no equations and therefore do not make the system matrices larger.

These variables are built-in variables with reserved variable names. If you use a parameter called `t`, for example, COMSOL Multiphysics uses it for a stationary study, but the time-dependent solver overrides it with the value of `t` from the solver. Any variable or parameter using one of these names can be overridden during solution or postprocessing. Avoid using these reserved variable names for user-defined parameters and variables, unless you are aware of how they are handled in COMSOL Multiphysics.

Geometric Variables, Mesh Variables, and Variables Created by Frames

The variables that characterize geometric properties and the mesh are listed in [Table 5-9](#), with detailed descriptions for some of the variables following the table.

TABLE 5-9: GEOMETRIC VARIABLES AND MESH VARIABLES

VARIABLE	DESCRIPTION
curv	The curvature of a boundary in 2D is called curv.
curv1, curv2	A boundary in 3D has two principal curvatures corresponding to the minimal and maximal normal curvatures. They are called curv1 and curv2, respectively. See Curvature Variables for details.
dGeomChar	The diagonal size of a bounding box containing all of the geometry.
dom	The domain number, the boundary number, the edge number, or the vertex (point) number (all are integer values). The variable sd also exists as an alias but is considered obsolete.
dvol	The volume scale factor variable, dvol, is the determinant of the Jacobian matrix for the mapping from local (element) coordinates to global coordinates. For 3D domains, this is the factor that the software multiplies volumes by when moving from local coordinates to global coordinates. In 2D and 1D domains, it is an area scaling factor and length scaling factor, respectively. If a moving mesh is used, dvol is the mesh element scale factor for the undeformed mesh. The corresponding factor for the deformed mesh is named dvol_spatial.
emetric2	Squared norm of the element metric emetric(<i>vector</i>). See emetric for details.
h	Available on all geometric entities, the variable h represents the mesh element size in the material/reference frame (that is, the length of the longest edge of the element).
linearizedelem	In some calculations, COMSOL Multiphysics forces mesh elements to become linear. This variable returns one inside such an element and zero otherwise. Note that the faces of the linearized mesh elements are not considered to be linearized themselves. You can use this variable to identify mesh elements with linearized elements.
meshtype	The mesh type index for the mesh element. This is the number of edges in the element.
meshelement	The mesh element number.
meshvol	Volume of the (linearized) mesh element.
nx, ny, nz	See Normal Variables .
qualskewness, qualmaxangle, qual, qualvollength, qualcondition, qualgrowth	Mesh quality measures. See Mesh Element Quality and Size . See also Frame Variables .
reldetjac reldetjacmin	The determinant of the Jacobian matrix for the mapping from the straight mesh element to the possibly curved element used when solving. Use this variable to measure the difference in shape between a curved element and the corresponding straight element. The variable reldetjacmin is a scalar for each element defined as the minimum value of the reldetjac variable for the corresponding element. A reldetjacmin value less than zero for an element means that the element is wrapped inside-out; that is, the element is an <i>inverted mesh element</i> .
s, s1, s2	See Parameterization Variables .

TABLE 5-9: GEOMETRIC VARIABLES AND MESH VARIABLES

VARIABLE	DESCRIPTION
tcurvx, tcurvy (2D) tcurv1x, tcurv1y, tcurv1z, tcurv2x, tcurv2y, tcurv2z (3D)	Tangential directions for the corresponding curvatures. See Curvature Variables for more information.
tmetric	Trace of the element metric <code>emetric(vector)</code> . See emetric for details.
t_x and t_y (2D) t_{1x}, t_{1y}, t_{1z} (3D edges and boundaries) t_{2x}, t_{2y}, t_{2z} (3D boundaries)	See Tangent Variables .
x, y, z r, z	See Spatial Coordinate Variables .
xi_1, xi_2, xi_3	Local (barycentric) coordinates ξ_i in each mesh element; see the section Finite Elements in the Elements and Shape Functions chapter.
<p>! When entering the spatial coordinate, parameterization, tangent, and normal geometric variables, replace the letters highlighted below in an <i>italic font</i> with the actual names for the dependent variables (solution components) and independent variables (spatial coordinates) for the Component node.</p>	

For example, replace u with the names of the dependent variables in the model, and replace x, y , and z with the first, second, and third spatial coordinate variable, respectively. x_i represents the i th spatial coordinate variable. If the model contains a deformed mesh or the displacements control the spatial frame (in solid mechanics, for example), you can replace the symbols x, y , and z with either the spatial coordinates (x, y , and z by default) or the material (reference) coordinates (X, Y , and Z by default).

The variables `curv`, `dvol`, `h`, `qual`, `reldetjac`, and `reldetjacmin` are based on the mesh viewed in the material (reference) frame. If you have a moving mesh, the corresponding variables for the mesh viewed in the spatial frame have a suffix `_spatial` (that is, `curv_spatial`, `dvol_spatial`, and so on). If you use a deformed geometry, the corresponding variables for the original, undeformed mesh have a suffix `_mesh` (for example, `h_mesh`).

Spatial Coordinate Variables

- The spatial coordinate variables (independent variables) are available for all domain types.
- For a Cartesian geometry the default names for the spatial coordinates are x, y , and z (for the x, y , and z coordinates).
- For axisymmetric geometries the default names for the spatial coordinates are r, ϕ , and z (for the r, ϕ , and z coordinates).
- If a deformed mesh is used, x, y, z can be both the *spatial coordinates* (x, y, z) and the *material/reference coordinates* (X, Y, Z); see [Mathematical Description of the Mesh Movement](#).

- If the model includes a deformed mesh, the variables `xTIME`, `yTIME`, and `zTIME` represent the mesh velocity. To access these variables, replace x , y , and z with the names of the spatial coordinates in the model (x , y , and z).
- If the model includes a deformed geometry, the default names for the spatial coordinates in the geometry frame and the mesh frame are X_g , Y_g , and Z_g (for the x_g , y_g , and z_g coordinates).

Most physics interfaces are based on a formulation which is either Eulerian or Lagrangian. They therefore lock their dependent variables to the spatial or the material frame, and the spatial derivatives are then defined with respect to x , y , and z (spatial frame) or X , Y , and Z (material frame), when using the default names for the spatial coordinates. See [Differentiation in Space](#).

PARAMETERIZATION VARIABLES

The surface-boundary parameterization variables can be useful for defining distributed loads and constraints such as a parabolic velocity profile. The available parameterization variables are:

The curve parameter s (or $s1$) in 2D. Use a line plot to visualize the range of the parameter, to see if the relationship between x and y (the spatial coordinates) and s is nonlinear, and to see if the curve parameterization is aligned with the direction of the corresponding boundary. In most cases it runs from 0 to 1 in the direction indicated by the arrows shown on the edges when in the boundary or edge selection mode and if you have selected the **Show edge direction arrows** check box in the **Settings** window for **View** (). You can use s on boundaries in 2D when specifying boundary conditions.

The arc length parameter $s1$ available on edges in 3D. It is approximately equivalent to the arc length of the edge. Use a line plot to visualize the values of $s1$.

The surface parameters $s1$ and $s2$ in 3D are available on boundaries (faces). They can be difficult to use because the relationship between x , y , and z (the spatial coordinates) and $s1$ and $s2$ is nonlinear. Often it is more convenient to use expressions with x , y , and z for specifying distributed boundary conditions. To see the values of $s1$ and $s2$, plot them using a surface plot.

TANGENT AND NORMAL VARIABLES

The tangent and normal variables are components of the tangential and normal unit vectors.

Tangent Variables

In 2D, \mathbf{tx} and \mathbf{ty} define the curve tangent vector associated with the direction of the boundary.

In 3D, the tangent variables $\mathbf{t1x}$, $\mathbf{t1y}$, and $\mathbf{t1z}$ are defined on edges. The tangent variables $\mathbf{t2x}$, $\mathbf{t2y}$, and $\mathbf{t2z}$ are defined on surfaces according to

$$(\mathbf{t}_{ix}, \mathbf{t}_{iy}, \mathbf{t}_{iz}) = k_i \left(\frac{\partial \mathbf{x}(s_1, s_2)}{\partial s_i}, \frac{\partial \mathbf{y}(s_1, s_2)}{\partial s_i}, \frac{\partial \mathbf{z}(s_1, s_2)}{\partial s_i} \right), \quad i = 1, 2$$

These most often define two orthogonal vectors on a surface, but the orthogonality can be ruined by scaling geometry objects. The vectors are normalized; k_i is a normalizing parameter in the expression just given.

If a deformed mesh is used, the tangent variables are available both for the deformed configuration and for the undeformed configuration. In the first case, replace x , y , and z with the spatial coordinate names (\mathbf{x} , \mathbf{y} , and \mathbf{z} by default). In the second case, replace x , y , and z with the material/reference coordinate names (\mathbf{X} , \mathbf{Y} , and \mathbf{Z} by default).

Normal Variables

In 1D, \mathbf{nx} is the outward unit normal pointing out from the domain.

In 2D, \mathbf{nx} and \mathbf{ny} define a normal vector pointing outward relative to the domains.

In 3D, \mathbf{nx} , \mathbf{ny} , and \mathbf{nz} define a normal vector pointing outward relative to the domains.

Direction of the Normal Component on Interior Boundaries

To get control of the direction of the normal component on interior boundaries, the following variables are available:

In 1D:

- \mathbf{unx} , the outward unit normal seen from the upper domain
- \mathbf{dnx} , the outward unit normal seen from the lower domain

In 2D:

- \mathbf{unx} and \mathbf{uny} for the up direction
- \mathbf{dnx} and \mathbf{dny} for the down direction

The upside is defined as the left side with respect to the direction of the boundary.

In 3D:

- unx , uny , and unz for the up direction
- dnx , dny , and dnz for the down direction

To visualize any of these vector variables use arrow plots on surfaces or lines.

If a deformed mesh is used, the normal variables are available both for the deformed configuration and for the undeformed configuration. In the first case, replace x , y , and z with the spatial coordinate names (x , y , and z by default). In the second case, replace x , y , and z with the material/reference coordinate names (X , Y , and Z by default).

Normal Vector Variables Representing Element Surface Normals

A similar set of variables — nxmesh , unxmesh , and dnxmesh , where x is the name of a spatial coordinate — use the element shape function and are normal to the actual element surfaces rather than to the geometry surfaces.

Normal Vector Continuous Variables

The names are similar to those for the standard normal vector variables except, that they have a c appended at the end: For example, nxc , nyc , and nzc in a 3D model or nrc and nzc in a 2D axisymmetric model. If you have a material frame and a spatial frame in a 3D model, the normal vector continuous variables are nxc , nyc , and nzc for the spatial frame and nXc , nYc , and nZc for the material frame. These variables are continuous within each boundary (but typically discontinuous where boundaries meet). It is possible to compute their tangential derivatives with the dtang operator as, for example, $\text{dtang}(\text{nxc}, x)$. Computing tangential derivatives in this way works only when the normal variable and the coordinate in the second argument of dtang belong to the same frame; $\text{dtang}(\text{nxc}, x)$ and $\text{dtang}(\text{nXc}, X)$ both work, but $\text{dtang}(\text{nXc}, x)$ and $\text{dtang}(\text{nxc}, X)$ are both 0.

CURVATURE VARIABLES

The curvature variables are defined on boundaries in 2D and 3D.

In 2D, the curvature is denoted curv . Positive curvature is toward the normal (nx, ny).

In 2D axisymmetry, the curvature variables refer to the curvature of the 2D geometry and use the same naming as in 2D. The second curvature, which is induced by the axisymmetry, is $-\text{nr}/r$ (using the default radial space variable name r) and has no predefined variable.

In 3D, there are two principal curvatures named curv1 and curv2 , where curv1 is less than curv2 and seen as real numbers. These correspond to the minimal and maximal values for the curvature of a curve you get by intersecting the boundary with a plane in which the normal lies. Positive curvature is toward the normal ($\text{nx}, \text{ny}, \text{nz}$).

The components of the normalized tangential directions for the corresponding curvatures are called tcurvx , tcurvy in 2D and tcurv1x , tcurv1y , tcurv1z , tcurv2x , tcurv2y , and tcurv2z in 3D. The tangents ($\text{tcurv1x}, \text{tcurv1y}, \text{tcurv1z}$) and ($\text{tcurv2x}, \text{tcurv2y}, \text{tcurv2z}$) are orthogonal.

Curvature variables are defined for all separate frames in a model. The names of the curvature variables in the spatial, mesh, and geometry frame are formed by appending the suffix $_{\text{spatial}}$, $_{\text{mesh}}$, and $_{\text{geometry}}$, respectively, to the name curv (in 2D and 2D axisymmetry) or curv1 and curv2 (in 3D). The variables without suffix always refer to the curvature in the material frame. Note that the variables with suffix are defined only if the spatial, mesh, or geometry frame actually is different from the material frame. For more information about frames and deformed mesh configurations, see [Deformed Mesh Fundamentals](#).

In the normalized tangent variable names, replace x , y , and z with the coordinate names in another frame to get the tangents in that frame.

FRAME VARIABLES

The following predefined variables are created by the spatial frame and can be of interest, for example, to monitor the quality of the mesh and define a stop criterion for remeshing (see [Adding a Stop Condition](#)):

- The local relative element volume, `spatial.relVol`, is a quantity that measures the local volumetric distortion of the elements. When this measure approaches zero in some part of the mesh, frame transformations become singular causing solvers to fail.
- The minimum relative element volume, `spatial.relVolMin`, must be > 0 ; otherwise, the mesh elements are inverted. A suitable stop criterion using this variable is that the minimum relative element volume must be larger than a small positive number.
- The maximum relative element volume, `spatial.relVolMax`, is a positive scalar number that represents the maximum value of the relative element volume.
- The minimum mesh quality, `spatial.minQual`, must be > 0 ; an acceptable mesh quality is typically larger than 0.1 (where the quality measure is a number between 0 and 1).

Material Group Indicator Variables

These variables make it possible to identify groups of geometric entities share material property expressions. There is a variable for each geometric entity level, and they evaluate to different (but arbitrary) integers on different groups of domains where material property expressions are the same within each group. The following variables are available:

- `material.domain`
- `material.boundary`
- `material.edge`
- `material.point`
- `material.entity`, which is defined on all entity levels.

The applicable variables (except `material.entity`) are available for postprocessing under **Model>Material** in the lists of predefined quantities for expressions in plots, for example.

These variables are useful for smoothing plot data across entity boundaries within the group but not across groups with different materials. The option **Inside material domains** available in the **Smoothing** list in quality settings for plots uses these variables. See [Entering Quality Settings for Plot Settings Windows](#).

Shape Function Variables

A finite element defines a number of variables, typically a dependent variable and its derivatives. Such variables are called shape functions variables because they are computed directly from *shape functions* and the degrees of freedom.

When a physics interface is selected, you can enter names for the dependent variables; these names are used to construct the finite elements. The dependent variable name is the basis for additional variable names that the finite elements generate.

When entering the shape function variables, replace the letters highlighted below in *italic font* with the actual names for the dependent variables (solution components) and independent variables (spatial coordinates) for the Component.

For example, replace u with the names of the dependent variables in the individual Component, and replace x, y , and z with the first, second, and third spatial coordinate variable, respectively. x_i represents the i th spatial coordinate variable. If the Component contains a deformed mesh or the displacements control the spatial frame (in solid mechanics, for example), you can replace the symbols x, y, z with either the spatial coordinates (x, y , and z by default) or the material/reference coordinates (X, Y , and Z by default).

AN EXAMPLE OF LAGRANGE ELEMENT VARIABLES

For the Lagrange element, which is the element type used by most physics interfaces, [Table 5-10](#) lists the available variable names, assuming you gave the name u as the argument to the shape function, and that the names x, y , and z are provided for the independent variables.

TABLE 5-10: LAGRANGE ELEMENT VARIABLE NAMES

ENTITY TYPE\\SPACE DIMENSION	ID	2D	3D
POINT		u	u
EDGE			u, uTx, uTy, uTz
BOUNDARY	u, uTx, ut, uTxt	u, uTx, uTy, ut, uTxt, uTyt	u, uTx, uTy, uTz, ut, uTxt, uTyt, uTzt
DOMAIN	u, ux, uxx, ut, uxt, uxxt, utt, uxtt, uxxtt,	u, ux, uy, uxx, uxy, uyx, uyy, ut, uxt, uyt, uxxt, uxyt, uyx, uyyt, utt, uxtt, uyt, uxxtt, uxytt, uyxtt, uyytt	u, ux, uy, uz, uxx, uxy, uxz, uyx, uyy, uyz, uzx, uzy, uzz, ut, uxt, uyt, uzt, uxxt, uxyt, uxt, uyx, uyyt, uyzt, uzxt, uzyt, uzzt, utt, uxtt, uyt, uzt, uxxt, uxytt, uyxtt, uyytt, uyztt, uzxtt, uzytt, uzztt

For example, with a fluid flow physics interface, you get the set of variables indicated in [Table 5-10](#) for u, v, w , and p , respectively.

- The variables ux, uy , and uz are the components of the gradient ∇u , that is, the 1st-order spatial derivatives.
- The variables $uxx, uxy, uxz, uyx, uyy, uyz, uzx, uzy$, and uzz are the 2nd-order space derivative components. They are meaningful only if the degree of the polynomial shape function used in an element is high enough. For first-order elements all these variables evaluate to zero.
- For elements with 2nd-degree polynomial shape functions (2nd-order elements), the polynomial degree of the 2nd-order derivatives is zero; that is, the second derivatives are constant in each element.
- For element orders lower than two, the second derivatives evaluate to zero regardless of the values of the 2nd-order derivatives of the true solution.

If the model uses a deformed mesh, each finite element is associated with a certain frame (the spatial frame or the material frame). The frame determines the names of the variables generated by the finite element. For instance, if the spatial frame is used, the Lagrange element computes derivatives with respect to the spatial coordinates, ux, uy , and uz . If the material frame is used, the Lagrange element computes derivatives with respect to the material coordinates uX, uY , and uZ .

THE TIME DERIVATIVES OF THE DEPENDENT VARIABLES

The variable ut is the time derivative of the dependent variable u . You can also form mixed space-time derivatives as $ux;t$, for example, uxt ,

$$\frac{\partial^2 u}{\partial x \partial t}$$

The `t` must be last in a mixed derivative. The second time derivatives can also be used, such as `utt` or `uxtt` (but not higher derivatives in time).

If the model contains a deformed mesh, there is, in addition to the usual time derivative `ut`, the *mesh time derivative* `uTIME`. This also holds for mixed space-time derivatives.

TANGENTIAL DERIVATIVE VARIABLES

On boundaries, edges, and points you also have access to *tangential derivative variables*. They have names such as `uTx`, `uTy`, and `uTz`. Using these variables, it is possible to create models with phenomena on boundaries, edges, or points as described with PDEs.

The tangential derivative variables represent the Cartesian components of the tangential projection of the gradient of shape function variables:

$$(\nabla u)_T = (I - \mathbf{n}\mathbf{n}^T) \cdot \nabla u$$

In this equation, $(\nabla u)_T$ is the tangential gradient, which consists of the tangential derivatives in each spatial direction, I is the unity tensor, \mathbf{n} is the outward unit normal vector, and ∇u is the gradient of u .

LAGRANGE MULTIPLIER VARIABLES

If weak constraints are activated for boundary conditions that are constraints (Dirichlet boundary conditions), COMSOL Multiphysics adds variables for the Lagrange multipliers (one for each dependent variable) by adding `_1m` as a suffix to the dependent variable name. For example, for a dependent variable `u`, the corresponding Lagrange variable is `u_1m`. The Lagrange multipliers are available on boundaries, and you can also evaluate them on edges (in 3D) and points (in 2D and 3D).

VARIABLE INHERITANCE

On boundaries, edges, and points, gradients and second derivatives of the shape functions are available by *inheritance*; that is, the average of the values of the variables from the adjacent domains are computed. This process can progress for several levels.

For example, `ux` is the average on a boundary from the adjacent domains, then the average on an edge from the adjacent boundaries, and finally, the average at the points from the adjacent edges.

If possible, avoid using variable inheritance for gradients and second derivatives in a model. Instead, use the tangential derivative variables for equation-based modeling on boundaries.

For computations of integrals of reaction forces and fluxes, use the `reacf` operator.

For high accuracy reaction forces and fluxes in other circumstances, use weak constraints and Lagrange multipliers on boundaries instead of directly accessing the gradient through inheritance (see [Computing Accurate Fluxes](#)).

When you plot or evaluate — on a boundary, for example — the value of a variable that is discontinuous across that boundary (a thin resistive layer, for example), the value is the average of the value on the “up” and “down” sides of the boundary. You can use the `up` and `down` operators to get the value on either side of the boundary (see [up and down](#)).

Solver Variables

The following table lists global solver variables that are available during the solution process only. They can be used in solver settings in the Study branches but are not available for use in, for example, results evaluations and plots.

TABLE 5-11: SOLVER VARIABLES

VARIABLE	DESCRIPTION
niterCMP	This variable contains the iteration number for nonlinear iterations. It starts from one and increases with one for each fully coupled or segregated iteration. It is used by some physics to control damping mechanisms. Examples are pseudo-time stepping in fluid dynamics and the penalty factor in the augmented Lagrangian method for contact problems in structural mechanics.
gmg_level	This variable contains the geometric multigrid level. It is zero for the top level (the one solved for), one for the next coarser level, and so on. It is used by some physics interfaces to control artificial stabilization.
timestep	This variable contains the current time step used by the time-dependent solver. It is used by some physics interfaces to control artificial stabilization. You can use it, for example, to create a stop condition that stops the time stepping if the time step becomes smaller than some threshold value.
currentiter	This variable contains the current iteration used by study steps that create For and End For nodes in the solver sequence. It is used by some physics interfaces, for example, to compute the average value of a quantity over several iterations of the solver sequence.

Entering Ranges and Vector-Valued Expressions

You can enter ranges and vector-valued expressions such as extra grid-line coordinates using the following formats:

- A space-separated or comma-separated list of values: 10, 15, 23, 29.7, 30.
- A delimited space-separated list using curly braces; for example, using it as an argument to a function such as a mathematical function or a user-defined function: `cos({0 pi/4 pi/2})` or `an1({1, 2, pi, 14/2})`. The curly braces can also be used to create a scalar-vector multiplication such as `{0, 1, 2}*10` or as an elementwise array multiplication such as `{0, 1, 2}.*{10, 11, 13}`, which results in the array `{0, 11, 26}`.
- Equally-spaced values using the `range` function as in `range(start_value, step_size, end_value)`. For example, `range(0, 0.2, 3)` creates the values 0, 0.2, 0.4,..., 2.6, 2.8, and 3.0. The step size is 1 if you provide only start and end values and skip the step value. You can also use the `range` function as input to a user-defined function, for example: `an1(range(0, 1, 12))`.

`start_value` can be either smaller or larger than `end_value`. In the latter case, the step size must be negative. For example, `range(0, -5, -100)` creates the values 0, -5, -10, ..., -95, -100, while `range(0, 5, -100)` is an empty set of values.

Combine these formats in a single expression to create an array of values that contain an arbitrary number of segments with differently spaced values mixed with other freely specified values.

EXAMPLES USING THE RANGE FUNCTION

- `range(a, (b-a)/(n-1), b)` gives a list of n equally-spaced increasing values in the range $[a, b]$ if $b > a$ or decreasing values in the range $[b, a]$ if $a > b$.
- `10^range(-3, 3)` gives the exponentially increasing sequence $10^{-3}, 10^{-2}, \dots, 10^3$.
- `1^range(1, 10)` gives a sequence of length 10 where all elements equal 1. Multiplying the vector `1^range(1, n)` by a constant value a gives a vector of n elements all equal to a .
- `0^range(1, 5)` gives the sequence 0 0 0 0 0.

USING RANGES TO GENERATE ARRAYS

A convenient way to generate vectors of values is to use the **Range** dialog box, which you open by clicking the **Range** button () next to most of the fields that accept vectors of values.

In that dialog box, use the **Entry method** list to select the method to enter the values that define the range:

- Select **Step** to define range using a specified step size. See [Step and Number of Values](#).
- Select **Number of values** to define range using a specified number of values. See [Step and Number of Values](#).
- Select **Logarithmic** to define a logarithmic range of values. See [Logarithmic](#).
- Select **ISO preferred frequencies** to define the range using an octave or other interval of ISO preferred frequencies. To show this option, click the **Show** button () and select **Advanced Study Options**. It also appears if the model contains a physics interface that requires the Acoustics Module.

Step and Number of Values

Step to enter a step size or **Number of values** to specify the number of values in the array. Specify the start value for an array of values in the **Start** field. Enter the step size in the **Step** field or the number of values in the **Number of values** field, depending on the setting in the **Entry method** list. Specify the end value for the array of values in the **Stop** field. By default, the spacing of the values is linear, but you can select a function to apply to all values. To do so, choose one of the available arithmetic and trigonometric functions as well as user-defined functions and functions from materials (with a single argument) from the **Function to apply to all values** list. For example, select **exp10** to create an array of exponentially increasing values. The list includes the following functions:

- The default value **None**, which means linear spacing using the `range` function directly with the values specified.
- The exponential functions **exp10** (base-10 exponential function) and **exp** (base-e exponential function), which create exponentially-spaced values using the specified range of values as powers of 10 and of the mathematical constant e , respectively.
- The trigonometric functions **cos** (cosine) and **sin** (sine), which create sinusoidally varying values.
- The square root function **sqrt**, which creates a vector with values that are the square roots of the values specified.

Logarithmic

Use this entry method to set up a logarithmic range of values (frequencies, for example). Enter the **Start** value (f_{min} in the expression below), the **Stop** value (f_{max} in the expression below), and the **Steps per decade** (N in the expression below). The range then becomes $10^{\{range(\log10(f_{min}), 1/(N-1), \log10(f_{max}))\}}$

ISO Preferred Frequencies

To show this option, click the **Show** button () and select **Advanced Study Options**. This method requires a license for the Acoustics Module. Use this entry method to set up ISO preferred frequencies — a list of frequencies defined based on the preferred numbers of ISO 3. Enter the **Start frequency**, the **Stop frequency**, and an **Interval: Octave, 1/3 octave, 1/6 octave, 1/12 octave, or 1/24 octave**. For example, range of frequencies between 1 and 10 using an octave is {1, 2, 4, 8} and, using 1/3 octave, it is {1, 1.25, 1.6, 2, 2.5, 3.15, 4, 5, 6.3, 8, 10}.

Common Settings

Click **Replace** to replace the contents in the field with the values specified in the **Range** dialog box.

Click **Add** to add the range of values to the end of the existing values in the associated field. That way you can create more complex ranges.

For ranges that contain integer values only, an **Integer Range** dialog box opens instead of the normal **Range** dialog box. The **Integer Range** dialog box only contains **Start**, **Step**, and **Stop** fields, all of which must contain integer values.

SUPPORT FOR RANGES AND VECTOR-VALUED EXPRESSIONS

The following modeling settings support ranges and vector-valued expressions:

- Extra grid lines in the **Settings** window for **Axis**.
- Interval coordinates when using the **Settings** window for **Interval** for 1D geometries.
- The **Copy**, **Move**, and **Rotate** transforms for geometry modeling.
- The times for output from the time-dependent solver and the list of parameter values in the **Settings** windows for study step nodes for time-dependent and stationary solvers and for parametric sweeps.
- The contour levels, the streamline start-point coordinates, and the coordinates in arrow plots. Whenever you specify a number of coordinates in **Settings** windows for plots, the COMSOL Multiphysics software uses scalar expansion — if one component is the same for all coordinates, enter a single number in the corresponding text field. For example, to get 101 linearly spaced coordinates from $y = 6$ to $y = 7$ along $x = 3$, enter it as the single scalar 3 for x and then `range(6,0.01,7)` for y . Thus, you need not enter 101 similar values for x .
- Element distribution in the meshing settings.

Because the `range` function returns a list of values, it is a vector-valued function that you cannot use in a definition of a variable, for example. Variables must return a scalar value.

Summary of Built-In Variables With Reserved Names

This section is an overview of the built-in elements of the following categories as defined by the underlying COMSOL Multiphysics language:

- Constants
- Variables
- Functions

These language elements are built-in or user-defined. In addition there are *operators* that cannot be user-defined, and *expressions*, which are always user-defined.

ABOUT RESERVED NAMES

Built-in variables have *reserved names*, names that cannot be redefined by the user. It is not recommended to use a reserved variable name for a user-defined variable, parameter, or function. For some of the most common reserved variable names, such as `pi`, `i`, and `j`, the text where you enter the name turns orange and you get a tooltip message if you select the text string. Reserved function names are reserved only for function names, which means that such names can be used for variable and parameter names, and vice versa. The following tables list most built-in elements and hence those reserved names.

CONSTANTS AND PARAMETERS

There are three different types of constants: built-in *mathematical and numerical constants*, built-in *physical constants*, and *parameters*. Parameters are user-defined constants that can vary over parameter sweeps. Constants are scalar valued. The following table lists the built-in physical constants. Constants and parameters can have units.

BUILT-IN PHYSICAL CONSTANTS

TABLE 5-12: BUILT-IN PHYSICAL CONSTANTS

NAME	DESCRIPTION
g_const	Acceleration of gravity
N_A_const	Avogadro constant
k_B_const	Boltzmann constant
Z0_const	Characteristic impedance of vacuum (impedance of free space)
me_const	Electron mass
e_const	Elementary charge
F_const	Faraday constant
alpha_const	Fine-structure constant
G_const	Gravitational constant
V_m_const	Molar volume of ideal gas (at 273.15 K and 1 atm)
mn_const	Neutron mass
mu0_const	Permeability of vacuum (magnetic constant)
epsilon0_const	Permittivity of vacuum (electric constant)
h_const	Planck's constant
hbar_const	Planck's constant over 2 pi
mp_const	Proton mass
c_const	Speed of light in vacuum
sigma_const	Stefan-Boltzmann constant
R_const	Universal gas constant
b_const	Wien displacement law constant

BUILT-IN MATHEMATICAL FUNCTIONS

These functions do not have units for their input or output arguments.

TABLE 5-13: BUILT-IN MATHEMATICAL FUNCTIONS

NAME	DESCRIPTION
abs	Absolute value
acos	Inverse cosine (in radians)
acosh	Inverse hyperbolic cosine
acot	Inverse cotangent (in radians)
acoth	Inverse hyperbolic cotangent
acsc	Inverse cosecant (in radians)
acsch	Inverse hyperbolic cosecant
arg	Phase angle (in radians)
asec	Inverse secant (in radians)
asech	Inverse hyperbolic secant
asin	Inverse sine (in radians)
asinh	Inverse hyperbolic sine
atan	Inverse tangent (in radians)
atan2	Four-quadrant inverse tangent (in radians)
atanh	Inverse hyperbolic tangent

TABLE 5-13: BUILT-IN MATHEMATICAL FUNCTIONS

NAME	DESCRIPTION
besselj	Bessel function of the first kind
bessely	Bessel function of the second kind
besseli	Modified Bessel function of the first kind
besselk	Modified Bessel function of the second kind
ceil	Nearest following integer
conj	Complex conjugate
cos	Cosine
cosh	Hyperbolic cosine
cot	Cotangent
coth	Hyperbolic cotangent
csc	Cosecant
csch	Hyperbolic cosecant
erf	Error function
exp	Exponential
floor	Nearest previous integer
gamma	Gamma function
imag	Imaginary part
log	Natural logarithm
log10	Base-10 logarithm
log2	Base-2 logarithm
max	Maximum of two arguments
min	Minimum of two arguments
mod	Modulo operator
psi	Psi function and its derivatives
range	Create a range of numbers
real	Real part
round	Round to closest integer
sec	Secant
sech	Hyperbolic secant
sign	Signum function
sin	Sine
sinh	Hyperbolic sine
sqrt	Square root
tan	Tangent
tanh	Hyperbolic tangent

The following table summarizes the built-in variables and constants that are generally available in all COMSOL Multiphysics models. Some are only available in certain geometries or in time-dependent models, for example. These variable names are reserved names and appear in orange in the **Settings** windows for parameters and variables.

TABLE 5-14: BUILT-IN VARIABLES AND CONSTANTS

NAME	DESCRIPTION	TYPE
t	Time.	Scalar
freq	Frequency.	Scalar
lambda	Eigenvalues.	Scalar
phase	Phase angle.	Scalar
numberofdofs	Number of degrees of freedom.	Scalar
x, y, z, r, X, Y, Z, R	Position.	Field
s, s1, s2	Edge/surface parameters.	Field
n, nx, ny, nz, nr	Edge/surface normals.	Field
tx, ty, tz, tr	Edge tangents.	Field
t1x, t1y, t1z, t2x, t2y, t2z	Surface tangents.	Field
un, unx, uny, unz	Edge/surface upward normals.	Field
dn, dnx, dny, dnz	Edge/surface downward normals.	Field
eps, i, j, pi, inf, Inf, nan, NaN	Numerical constants.	Scalar
h	Local mesh element size (length of the longest element edge).	Field
dom	The domain number, boundary number, edge number, or point number.	Field
meshtype	Mesh type index for the mesh element; this is the number of edges in the element.	Field
meshelement	Mesh element number.	Field
meshvol	Volume of the (linearized) mesh element.	Field
dvol	Volume scale factor variable; this is the determinant of the Jacobian matrix for the mapping from local (element) coordinates to global coordinates.	Field
qual	A mesh quality measure between 0 (poor quality) and 1 (perfect quality). The absolute value of the mesh element quality is based on the ratios of the inscribed and circumscribed circles' or spheres' radii for the simplex corresponding to each corner of the element. A negative value means a contradiction to the numbering convention for mesh element vertices and the element is then referred to as an inverted element.	Field
reldetjac	Determinant of the Jacobian matrix for the mapping from the straight mesh element to the possibly curved element used when solving.	Field
reldetjacmin	The minimum value of the reldetjac variable in each element.	Field
linearizedelem	One inside elements that have been linearized; zero otherwise.	Field
niterCMP	Iteration number for nonlinear iterations.	Scalar
gmg_level	Geometric multigrid level.	Scalar
timestep	Current time step.	Scalar

TABLE 5-14: BUILT-IN VARIABLES AND CONSTANTS

NAME	DESCRIPTION	TYPE
particleindex	A unique positive integer to define each particle or ray. This variable is only defined when using the Geometrical Optics interface, Ray Acoustics interface, or one of the particle tracing physics interfaces.	Scalar
particlestatus	An integer that corresponds to the status of a particle or ray, which indicates whether the particle or ray is active or has been subjected to certain types of boundary conditions. This variable is only defined when using the Geometrical Optics interface, Ray Acoustics interface, or one of the particle tracing physics interfaces. By default it cannot be used during postprocessing.	Scalar

The suffixes x , y , z , and r in some of the variables are the default names for the spatial coordinates, which you can change if desired.

The following user-defined variables generate built-in variables such as space and time derivatives. See [Shape Function Variables](#) for information about those built-in variables.

TABLE 5-15: USER-DEFINED VARIABLES THAT GENERATE BUILT-IN VARIABLES

DEFAULT NAME	DESCRIPTION	TYPE
x, y, z	Spatial coordinates (Cartesian)	Field
r, z	Spatial coordinates (cylindrical)	Field
u, T , and so on	Dependent variables (solution)	Field

Mass Properties

Introduction

You can add one or more **Mass Properties** nodes to create variables for and compute the following quantities for a model component:

- The volume of the geometry or part of the geometry.
- The mass of the geometry or part of the geometry
- The center of mass
- The moment of inertia
- The principal moment of inertia

When you compute the solution, COMSOL Multiphysics adds the following variables:

TABLE 5-16: VARIABLES CREATED BY A MASS PROPERTIES NODE

QUANTITY	TYPICAL VARIABLE NAMES
Volume	mass1.volume
Mass	mass1.mass
Center of mass	mass1.CMX, mass1.CMY, mass1.CMZ
Moment of inertia	mass1.IXX, mass1.IXY, mass1.IXZ, and so on
Moment of inertia, principal direction	mass1.Ip1X, mass1.Ip2X, mass1.Ip3X, and so on
Moment of inertia, principal values	mass1.Ip1, mass1.Ip2, and mass1.Ip3

The namespace of the variables — `mass1` in the table — is unique for each **Mass Properties** node.

In general, the characters X, Y, and Z in the variable names in the table above are replaced by the coordinate names in the selected frame.

Use a **Global Evaluation** node, for example, to evaluate the resulting measurement quantities, which you can select from a **Definitions>Mass Properties** submenu after clicking the **Replace Expression** () or the **Insert Expression** () button.

Mass Properties

In the **Definitions** toolbar, click to add a **Mass Properties** () node and compute the variables for mass, volume, center of gravity, and moment of inertia. Under a **Component** you can also right-click **Definitions** to add this feature from the **Variable Utilities** submenu.

The **Settings** window for a **Mass Properties** node includes the following sections:

SOURCE SELECTION

The source selection defines the source for the mass property variables — the part of the geometry over which the program computes the measurement variables and to which the density contribution is limited. You can add other density contributions by right-clicking the **Mass Properties** node and choosing **Mass Contributions** (); see [Mass Contributions](#).

From the **Geometric entity level** list, select **Domain** (the default), **Boundary**, **Edge** (3D only), or **Point**. Select **Manual** or **All domains** (the default), **All boundaries**, **All edges**, or **All points** from the **Selection** list. If **Manual** is selected, select geometric entities in the **Graphics** window.

DENSITY

In this section you define the source of the density values used for computing some of the mass properties using the **Density source** list:

- Choose **User defined** (the default), to define a value or expression for the density in the **Density expression** field (SI unit: kg/m³). For example, `material1.rho`, which is a variable for the density from the materials in the model. From the **Density input frame** list, choose the frame to use for the integration: **Material** (the default in 3D), or **Spatial**. When the output frame is the geometry frame, the input density is transformed to the material frame. Note that the actual coordinate names — typically **(x, y, z)** or **(X, Y, Z)** in 3D — are displayed for each frame, indicating which frames differ from each other in the current model.
- Choose **From physics interface** to take the density from the active physics interface in the geometry. If there are two or more physics interfaces that provide a density in the same domain, the density used can be from any of the physics interfaces (but the density is then typically the same in those physics interfaces). The **Include adjacent entities of lower dimension** check box is selected by default to include the density also on adjacent boundaries, edges, and points.
- Choose **From specified physics interface** to take the density from a physics interface that you choose from the **Physics** list. The **Include adjacent entities of lower dimension** check box is selected by default to include the density also on adjacent boundaries, edges, and points.

VARIABLES

In this section, select the variables to create and on which frame these are defined.

From the **Frame** list, choose the frame to use when computing the mass properties: **Material** (the default in 3D), **Geometry**, or **Spatial**. Note that the actual coordinate names — typically **(x, y, z)** or **(X, Y, Z)** in 3D — are displayed for each frame, indicating which frames differ from each other in the current model.

The following check boxes are selected by default to create and compute the corresponding mass property:

- Create volume variable** to create a variable for the volume of the selected geometric entities.
- Create mass variable** to create a variable for the mass of the selected geometric entities.
- Create center of mass variables** to create variables for the center of mass of the selected geometric entities.
- Create moment of inertia variables** to create variables for the moment of inertia of the selected geometric entities.
- Create principal moment of inertia variables** to create variables for the principal moment of inertia of the selected geometric entities.

These variables are available in, for example, a **Global Evaluation** node under **Results>Derived Values**. Click the **Insert Expression** () or **Replace Expression** () button to choose one of the mass property values such as **Model>Component1>Definitions>Mass Properties1>Center of mass>mass1.CMY** for the Y-component of the center of mass.

INTEGRATION SETTINGS

Specify the integration order of the integration used to compute the output variables (see **integration order** in the *Glossary*). The default in the **Integration order** field is 4 (which typically is twice the order of the shape order function for the physics).

Mass Contributions

In the **Definitions** toolbar, click to add a **Mass Contributions** () node, which you can use to add contributions to the mass used for computing the mass properties in the parent **Mass Properties** node. Under **Definitions**, you can also right-click **Mass Properties** to add this feature.

The contributions can come from a connected boundary, for example. The **Settings** window for a **Mass Contribution** node includes the following sections:

SOURCE SELECTION

The source selection defines the source for the mass contribution to the mass properties — the part of the geometry where you want to add mass contributions.

From the **Geometric entity level** list, select **Domain** (the default), **Boundary**, **Edge** (3D only), or **Point**. Select **Manual** or **All domains** (the default), **All boundaries**, **All edges**, or **All points** from the **Selection** list. If **Manual** is selected, select geometric entities in the **Graphics** window.

DENSITY

In this section you define the source of the density values used for computing some of the mass properties using the **Density source** list:

- Choose **User defined** (the default), to define a value or expression for the density in the **Density expression** field (SI unit: kg/m³). For example, `material1.rho`, which is a variable for the density from the materials in the model. From the **Density input frame** list, choose the frame to use for the integration: **Material** (the default in 3D), **Mesh**, **Geometry**, or **Spatial**. Note that the actual coordinate names — typically **(x, y, z)** or **(X, Y, Z)** in 3D — are displayed for each frame, indicating which frames differ from each other in the current model.
- Choose **From physics interface** to take the density from the active physics interface in the geometry. If there are two or more physics interfaces that provide a density in the same domain, the first contributions are then overwritten by the last one (but the density is then typically the same in those physics interfaces). The **Include adjacent entities of lower dimension** check box is selected by default to include the density also on adjacent boundaries, edges, and points.
- Choose **From specified physics interface** to take the density from a physics interface that you choose from the **Physics** list. The **Include adjacent entities of lower dimension** check box is selected by default to include the density also on adjacent boundaries, edges, and points.

Functions

User-defined functions can be added globally or locally:

- To add global functions, in the **Home** toolbar (Windows users) or Main toolbar (macOS and Linux users) select an option from the **Functions** menu from the **Global** submenu, or right-click the **Global Definitions** (≡) node.
- You can add local functions (for any **Component** branch), from two toolbars, either the **Definitions** toolbar in the **Functions** group, or in the **Home** toolbar (Windows users) or Main toolbar (macOS and Linux users), where you choose it from the **Local** submenu. You can also right-click the **Definitions** (≡) node and choose an option from the **Functions** submenu.

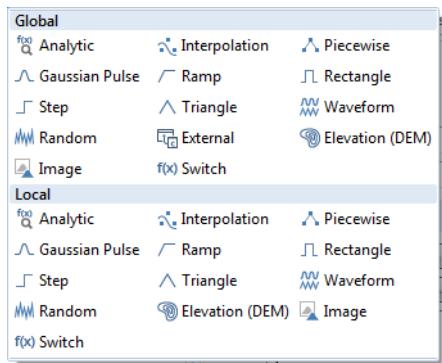

Figure 5-1: The Home toolbar menu for Functions divided into Global and Local submenus for a Windows user.

Switch for Functions

Use the **Switch** node (⊕) under the **Global Definitions** node (≡) to switch between global functions during a solver sweep. You add the functions as subnodes under the **Switch** node. The switch for functions acts essentially as a switch statement in a programming language; that is, it dynamically chooses one of its underlying branches depending on a parameter that can be controlled from the solvers using a **Function Sweep** study.

In addition to the **Label**, you can also enter a name for the switch in the **Function name** field (default: **sw1**). Use that function name where you want to switch across the functions under the **Switch** node using a function sweep. Without a sweep, the function name for the switch uses the first function node under the **Switch** node by default.

About User-Defined Functions

There are three broad categories of user-defined functions — **Analytic**, **Interpolation**, and **Piecewise** — and a number of templates for common function types, such as step and ramp functions. You can also create external function interfaces to include functions written in C and MATLAB®. Functions can be global or local in a model component, although *external functions* and *MATLAB functions* can only be defined globally.

User-defined functions (including functions defined by materials, thermodynamic property packages, M-files in MATLAB, and external DLLs) can be used in definitions of parameters and in a wide range of settings (where you can also use parameters), including definitions of geometry objects. To access user-defined functions defined under a component from other components and from nodes under **Global Definitions**, add the component's name as a prefix — for example, `comp1.f(x)`. You can also use a user-defined function (with a single argument) as the function to apply in the **Range** dialog box.

FUNCTION NAMES AND CALLING FUNCTIONS

Function names for built-in mathematical functions such as `abs`, `cos`, and `test` are reserved function names, and naming a user-defined function using one of the reserved function names is not recommended because it can cause unexpected results. If the name that you type in the **Function name** field is a reserved function name, the text color changes to orange, as a warning. If you move the cursor to a function name in orange, the tooltip **is a reserved name** is displayed.

If you want to use a user-defined function in the model settings or for postprocessing, then call it with its arguments, such as `func1(x,y)` for a function with two arguments describing a spatial variation in a 2D geometry.

PLOTTING FUNCTIONS

Click the **Plot** button () in the upper-right corner of the **Settings** window to plot any user-defined function of 1–3 variables directly in a separate **Function Plot** window.

Click the **Create Plot** button () in the upper-right corner of the **Settings** window to create a persistent plot of the function under **Results**, including a Grid data set with the function as the source data, a plot group and a plot feature. The added nodes can be used for plotting multiple functions on top of each other or for direct comparison to model results, for example.

For analytic functions, first define a range for the arguments in the **Plot Parameters** section. Note that the range is expressed in the current unit system's base unit corresponding to the set function argument unit. For example, if the current unit system is SI and the function argument unit is `cm`, the plot range is expressed in `m`.

Common Settings for the Function Nodes

UNITS

By default, functions expect dimensionless inputs and provide dimensionless outputs. When such a function is called with arguments having well-defined units (except when explicitly dimensionless), it is called with the numerical value of the argument expressed in the current unit system for the context where the function is used. The return value from the unit handling perspective behaves like a number, adapting its unit to the context where it is used.

In the **Units** section in the **Settings** window for the Analytic, Interpolation, and Piecewise function nodes, you can define units for the function's inputs and output. In the **Arguments** field, type a single unit for all inputs, or specify space-separated or comma-separated units for each input (type `m, s`, for example, for two input arguments with the units meter and second, respectively). In the **Function** field, type the unit for the function's output.

When using nested function calls, the unit handling for functions cannot always deduce the correct units. It is therefore recommended that you avoid using the settings in the **Units** section of the function features if you make nested function calls.

DERIVATIVES

For **External** functions and **MATLAB** functions, enter expressions for the partial derivatives of each function with respect to their input arguments. The derivative information is needed by the automatic Jacobian computation. In the **Derivatives** table, each row contains a partial derivative of a function with respect to one of its arguments:

- The entries in the **Function name** column must occur in the **Functions** table, and the entries in the **Argument** column must occur among the arguments listed for that function in the **Function** table.
- The **Partial derivative** column contains expressions for the partial derivatives. Partial derivatives that are not specified in the table default to 0.

PLOT PARAMETERS

Use this table to set the range for arguments in preview plots. For each argument, enter a **Lower limit**, and an **Upper limit** in the **Plot Parameters** table. In **Analytic** function plot settings, the argument column is updated automatically and must always match the specified argument list. For **External** and **MATLAB** functions, the argument column is absent. Instead, the limits specified in the table are applied to in order from top to bottom to the arguments of the first function with a matching number of arguments. It is also this first matching function that is plotted when you click the **Plot** button () or the **Create Plot** button ().

SMOOTHING

Smoothing makes a function more well-behaved and suitable for modeling. It replaces jumps with smooth transitions that eliminate discontinuities and can represent the inertia present in real applications. Use smoothing to improve the behavior of the model by avoiding discontinuities that are difficult to handle numerically. The smoothed functions have continuous first and, optionally, second derivatives.

For the **Step**, **Triangle**, and **Rectangle** functions, enter a value in the **Size of transition zone** field to control the amount of smoothing. Also, set the **Number of continuous derivatives** to **1** or **2**. The default is to make derivatives continuous up to second order. For the **Ramp** function, additionally specify a value, if desired, for the **Size of transition zone at start** and, if desired and a cutoff is active, a value for the **Size of transition zone at cutoff**. For the **Step** function, the step is the same as for the **f1c1hs** and **f1c2hs** smoothed step functions, depending on the settings in the **Number of continuous derivatives** list (see [Additional Smoothed Functions](#)). The parameter **d** in **f1c1hs(x,d)**, for example, is set to half of the value in the **Size of transition zone** field,

Note that smoothing affects for which values of the arguments the function is different from zero. In particular, when applying smoothing to a **Ramp** or **Step** function, it starts to rise before the position specified in the **Location** field. This may interfere with initialization assuming that the function is zero at this point.

The **Waveform** function also supports smoothing for some of the waveform types.

Analytic

An **Analytic** function () is defined by a symbolic expression. Analytic functions have the ability to bind arguments during function calls. In other words, they do not require the actual argument names in an expression when writing the function. For example, you can define a function $f(x) = x^2$ with the input argument **x** and the expression **x^2** and then call it as **f(T)**, where **T** is the temperature in a heat transfer model. The default **Function name** is **an1**.

The **Analytic**, **Interpolation**, and **Piecewise** functions can also be added to Materials. See [Using Functions in Materials](#).

- See [Function Names and Calling Functions](#) for information about allowed function names.
- See [Units](#) for information about the **Unit** section.
- See [Plot Parameters](#) for information about **Plot Parameters** (plot range) settings.

DEFINITION

In the **Expression** field, enter the mathematical expression that defines the function, such as **sin(x)*cos(y)+g_const** or **a+b*cos(c)**. Enter **Arguments** to the analytic function as comma-separated entries

(x , y and a , b , c for the functions above, respectively). In addition to the arguments that are defined, analytic functions also recognize global parameters and physical constants (such a `g_const` in the example above). It is also possible to call another function.

From the **Derivatives** list, **Automatic** is selected by default and computes the derivatives symbolically. The COMSOL Multiphysics software uses the derivatives of a function if a variable that depends on the solution is used in a function argument. Select **Manual** to specify the function derivatives with respect to its arguments in a table. If **Manual** is selected, enter the derivatives with respect to the function's arguments. For undefined derivatives, COMSOL Multiphysics uses 0 as the value of the derivative. In the second example above, enter a , b , and c in the top three rows of the **Argument** column, and 1 , $\cos(c)$, and $-b*\sin(c)$ in the associated text fields in the **Partial derivative** column.

PERIODIC EXTENSION

Select the **Make periodic** check box to make the function periodic and extend its definition within an interval to the whole real axis. Then define the interval by entering values in the **Lower limit** (default: 0) and **Upper limit** (default: 1) fields.

ADVANCED

Select the **May produce complex output for real arguments** check box if the defined function works similarly to `sqrt`; that is, if it sometimes returns complex values for a real-valued input.

- If you have the AC/DC Module, see *A Geoelectrical Forward Problem*: Application Library path **ACDC_Module/Other_Industrial_Applications/geoelectrics**.
- If you have the RF Module, see *Second Harmonic Generation of a Gaussian Beam*: Application Library path **RF_Module/Tutorials/second_harmonic_generation**.

Elevation (DEM)

The **Elevation (DEM)** function (ⓘ) makes it possible to import geospatial elevation data from digital elevation models (on the DEM file format using the USGS standard from the United States Geological Survey) and map the elevation data to a function of x and y . A DEM file contains elevation data for a portion of the Earth's surface. The resulting function behaves essentially like a grid-based interpolation function. The default **Function name** is `elev1`.

FILE

Enter the path and name of the elevation file in the **Filename** text field, or click **Browse** to select a DEM file with elevation data in the **Elevation Data** dialog box. When a DEM file is open, the **File** section displays the coordinates for the southeast corner.

Click **Import** to import the elevation data in the specified DEM file into the model; otherwise, COMSOL Multiphysics references the elevation data on your file system. When the elevation data is imported, the **File** section (under **Data imported into model**) contains information about the filename and the location for the data. Click **Export** to save the elevation data to a file and reference from that file instead of including it in the model. Click the **Discard** button to delete the imported data from the model. Click the **Refresh** button to reread the file.

INTERPOLATION AND EXTRAPOLATION

For interpolation in the elevation data, select an **Interpolation** method from the list: **Nearest neighbor** or **Linear** (the default).

For extrapolation of values that are outside the range in the elevation data, select an **Extrapolation** method from the list: **Constant** (the default), **Linear**, **Nearest function** (which evaluates the function from the closest grid point at the

actual point where a value is requested), or **Specific value**. For a **Specific value**, enter a value to **Replace missing data with** field (SI unit: m). The default is 0 m.

On the **Settings** window toolbar, click the **Create Surface** button () to add a **Parametric Surface** node to represent the elevation function as a parametric surface in the **Geometry** branch for 3D models.

External

The **External** function is only available with the **Global Definitions** node. See also `model1.func()` in the *COMSOL Multiphysics Programming Reference Manual* for details about the interface to external functions, including an example and information about compiling the function on the supported platforms.

An **External** function () interfaces with other external functions written in the C language (using a native C function or, through a wrapper function, interfacing with source code written in, for example, Fortran). You can use those functions as any other functions defined in COMSOL Multiphysics. For example, use it for a user-created shared library (depending on the platform, a DLL, .so, or .dylib file).

Go to [Common Settings for the Function Nodes](#) for information about the **Derivatives** and **Plot Parameters** sections.

FUNCTIONS

Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. For each row in the table, enter a **Function name** (myfun, for example) and a space-separated or comma-separated list of the names of its input **Arguments** (x y, for example).

ADVANCED

Enter a value in the **Initialization data** field. The value is sent to the library when it is loaded. Select the **Thread safe** check box to declare that the function is a thread-safe pure function (that is, a function that always returns the same results using the same input argument values and that does not have any side effects or output). Select this check box to improve performance.

Gaussian Pulse

The **Gaussian Pulse** function () is the common bell-shaped curve (Gaussian function). It has a shape that is similar to a Gaussian (normal) distribution. The default **Function name** is gp1.

The Gaussian pulse has the same characteristics as the normal distribution: it is a pulse with a shape that is similar to a normal or Gaussian distribution as a function:

$$y(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{\frac{-(x-x_0)^2}{2\sigma^2}}$$

In the equation above, x is the input variable, x_0 is the location (mean), and σ is the standard deviation. This function is a function of one variable (the time t , for example).

PARAMETERS

Enter a **Location** value for the Gaussian pulse mean x_0 (the default location is 0). Enter a **Standard deviation** σ of the normal distribution. The default is 1.

	<ul style="list-style-type: none">• If you have the RF Module, see <i>Transient Modeling of a Coaxial Cable</i>: Application Library path RF_Module/Verification_Examples/coaxial_cable_transient.• If you have the Chemical Reaction Engineering Module, see <i>Protein Adsorption</i>: Application Library path Chemical_Reaction_Engineering_Module/Mixing_and_Separation/protein_adsorption.
---	---

Image

The **Image** function () makes it possible to import an image (in BMP, JPEG, PNG, or GIF format) and map the image's RGB (red, green, blue) data to a scalar (single channel) function output value. By default the function's output uses the mapping $(R+G+B)/3$.

The default **Function name** is `im1`. An image is defined on a two-dimensional domain, and you typically call the image function using spatial coordinates: `im1(x,y)`.

	<ul style="list-style-type: none">• See Function Names and Calling Functions for information about the Function name section.• See Common Settings for the Function Nodes for information about the Units section.
---	---

FILE

Enter the path and name of the image file in the **Filename** text field, or click **Browse** to select an image file in the **Image** dialog box. Click **Import** to import the image in the specified image file into the model; otherwise, COMSOL Multiphysics references the image on your file system. When you have imported the image, the **File** section, under **Data imported into model**, contains information about the image's filename and size. Click **Export** to save the image to a file and reference it from there instead of keeping it in the model. Click the **Discard** button to delete the imported image data from the model. Click the **Refresh** button to reread the file.

COORDINATES

Define the 2D coordinates and if required, flip the image. Select the **In place** check box to use the pixels in the image as the coordinates. Click to clear the check box to define the image coordinates explicitly using the **x minimum**, **x maximum**, **y minimum**, and **y maximum** fields. Select the **Flip horizontally** check box to flip the image horizontally from left to right and vice versa. Select the **Flip vertically** check box to flip the image vertically from up to down and vice versa.

COLOR SCALING

From the **Scaling** list, select **Automatic** (the default) to use the default scaling, which outputs the mean of the RGB values for each pixel in the image. Select **Manual** to specify a custom expression for the scalar image function output value in the **Expression** field. The default is $(r+g+b)/3$, which is the automatic scaling, giving a scalar value that is the mean of the RGB values in each pixel.

For interpolation in the image, select an **Interpolation** method from the list: **Nearest neighbor** or **Linear** (the default).

For extrapolation of values that are outside the range in the image, select an **Extrapolation** method from the list: **Constant** (the default), **Linear**, **Nearest function** (which evaluates the function from the closest grid point at the actual point where a value is requested), or **Specific value**. If **Specific value** is selected, enter a value in the **Value outside range** field (default value: 0).

CLIPPING

Apply clipping to create a box-shaped region inside of the original image where the image is rendered. From the **Clipping** list, select **None** (the default) for no clipping, or **Manual** to define the box-shaped region using the **x minimum**, **x maximum**, **y minimum**, and **y maximum** fields (unit: px). The default **x maximum** and **y maximum** values are both 1000 px; the default minimum values are 0.

Interpolation

An **Interpolation** function () is defined by a table or file containing the values of the function in discrete points. The interpolation data can be structured (defined on a grid) or unstructured (defined on a generic point cloud).

The Analytic, Interpolation, and Piecewise functions can also be added to Materials. See [Using Functions in Materials](#).

DEFINITION

Select a **Data source** — **File**, **Local table** (the default), or **Result table** to define the interpolation function by entering values in a table or by importing interpolation data from a file or from a table under **Results**, respectively.

The data source for the interpolation must contain real-valued data only.

- If **Local table** is selected, enter a **Function name** and enter coordinates t and function values $f(t)$ into the table cells. A function of one variable can be defined in this way. For functions of two or more variables, such as space-dependent data in 2D and 3D, use a file with the function data. The default **Function name** is **int1**. You can move rows up and down in the table, remove a row from the table, and clear the table using the buttons underneath the table.
 - *Optional:* Save the parameters to a text file to reuse in other models. Click the **Save to File** button () and enter a **File name**, including the extension .txt. Click to **Save** the text file. The information is saved in space-separated columns in the same order as displayed on screen.
 - *Optional:* Import or Load data from a spreadsheet program or other format by saving the file with a .txt extension. Data must be separated by tabs or colons. Click the **Load from File** button () and navigate to the text (.txt) file to load and click **Open**. If the license includes LiveLink™ for Excel® you can also load interpolation data from a Microsoft Excel Workbook spreadsheet. The data loads to the table. If there is other data already in the table, it adds it after the last row. Move or edit as needed.
- If **File** is selected to import interpolation data from a file, select a **Data format**: **Spreadsheet**, **Grid**, or **Sectionwise**. If the license includes LiveLink™ for Excel®, you can also import interpolation data from a Microsoft® Excel Workbook spreadsheet. COMSOL Multiphysics then uses the spreadsheet format and the **Data format** list is not available.
 - When the data format is specified, enter the complete network path and name of the interpolation data file in the **Filename** field, or click **Browse** to select a text or data file with interpolation data in the **Interpolation Data** dialog box. Then click **Import** to import the interpolation data into the model; otherwise COMSOL Multiphysics references the interpolation data on your file system. When you have imported the interpolation data, the **Parameters** section, under **Data imported into model**, contains information about the filename, data type, and dimension for the data. Click **Export** to save the interpolation data to a file and reference from there

instead of including it in the model. Click the **Discard** button to delete the imported interpolation data from the model. Click the **Refresh** button to reread the file.

- From the **Data format** list select **Spreadsheet**, **Grid**, or **Sectionwise**. The spreadsheet format is the default format, and that format is the easiest to use for functions defined on an unstructured grid or for general tabulated function values with one or more arguments.
- If **Result table** is selected, interpolation data evaluated or imported into a table under **Results>Tables** is treated in the same way as a file using the spreadsheet format.

If the interpolation data is given on spreadsheet format and when using a result table, enter a **Number of arguments** (1–3). For all data formats and table sources, enter information about the functions into the table. Add a **Function name** and its **Position in file**. The first function in the file has position 1, the following has position 2, and so on. For spreadsheet data, the first columns contain the arguments (typically spatial coordinates); the following columns can contain one or more functions, and the positions entered are the relative position for each function's data column.

For unstructured interpolation data, COMSOL Multiphysics may internally apply a scaling of the coordinates of the data points to simplify the process of creating an interpolation mesh. Use the **Internal scaling of data points** list to control this functionality. Select **Automatic** (the default) to apply the scaling if the bounding box of the interpolation points has a bad aspect ratio, **On** to always apply the scaling, or **Off** to turn off scaling altogether.

Changing the scaling strategy may affect the generated interpolation mesh. The **Internal scaling of data points** list is only available when unstructured interpolation data can be entered (that is, when **Spreadsheet** or **Result table** is the data source).

For the common case where the data source contains function values that are functions of the spatial coordinates, select the **Use spatial coordinates as arguments** check box. Then select the frame to which the spatial coordinates are attached from the **Frame** list (the default is **Spatial** for the spatial frame). Then the function can be called without arguments when used in the model; the spatial coordinates are added as function arguments automatically. The **Use spatial coordinates as arguments** check box is available for **Interpolation** nodes in a **Component** branch when the **Data source** is **File** or when using a **Table** in 1D models.

The Interpolation functions support 1, 2, or 3 arguments. You cannot define functions with more than three (3) arguments because the algorithm creates a mesh for the point cloud, which is not possible in four dimensions or higher.

An Example of Importing a File Data Source into a Parameter Table

The file named `temp.txt` contains temperature measurements in nine points in the plane:

```
10 3 310
20 3 309
30 3 314
10 6 302
20 6 307
30 6 311
10 9 307
20 9 308
30 9 314
```

The data columns contain *x*-coordinates, *y*-coordinates, and temperature values, respectively. To use this file as an interpolation function called `tempfun`, perform the following steps.

- 1 Select **File** from the **Data source** list.
- 2 Enter a **Filename** (the complete network path) or **Browse** to locate a file to import.
- 3 From the **Data format** list select **Spreadsheet**.
- 4 Enter a **Number of arguments**. In this example, enter 2.

- 5 Enter the **Function** name `tempfun`.
- 6 Enter its **Position in file** as 1. The first function in the file has position 1, the following has position 2, and so on. The position in file for a function is the column after the spatial coordinates (or other function arguments) where it is defined. In this example with two arguments (spatial coordinates), the third column is Position 1 in the file.
- 7 If desired, adjust the interpolation and extrapolation settings in the **Interpolation and Extrapolation** section (see below).

Use the function `tempfun` with `x` and `y` as input arguments in a 2D model to get the interpolated value for the temperature at any position. If the **Use spatial coordinates as arguments** check box is selected, use `tempfun` without adding the input arguments.

Examples of Spreadsheet, Sectionwise, and Grid File Formats

In all file formats, use a % (percent) sign to indicate a comment line.

Spreadsheet File A *spreadsheet* file contains unstructured mesh and function data for space-dependent functions or general input variables and function values for functions of one or more variables.

%Header (optional)

Columns containing x, y (optional), and z (optional), or any other arguments, followed by function data columns.

The number of arguments is equal to the number of columns minus one, but there cannot be more than 3 arguments.

Sectionwise File A *sectionwise* file has coordinates and function values.

%Coordinates

One to three columns containing x, y (optional), and z (optional)

%Elements

Triangulation where each row contains the row indices of the points in the Coordinates section that make up one element (triangular in 2D, tetrahedral in 3D)

%Data (funname)

Column of data values for each point

It is possible to include more than one function in the file as long as a **%Data** header separates them one from the other.

Grid File A *grid* file

%Grid

x grid points separated by spaces

y grid points separated by spaces (optional)

z grid points separated by spaces (optional)

%Data

Data values separated by spaces

Each row contains values for different `x` grid points for fixed values of `y` and `z`. The rows first increase the `y` grid value and then the `z` grid value. The grid points can also represent another independent variable that the data values depend on. For example, the “grid points” can be temperature values and the data values the thermal conductivity at these temperatures.

It is possible to include more than one function in the file as long as a %Data header separates them one from the other.

It is important to use a comment line starting with % to separate the grid points or other interpolation points and the data values that are associated with these coordinates or interpolation points.

INTERPOLATION AND EXTRAPOLATION

The interpolation and extrapolation settings control how the program evaluates the function between the discrete points where it is defined by the table or file, and the behavior of the function outside the domain where it is defined by the table or file.

Select an **Interpolation** method:

- For functions of one variable select **Nearest neighbor**, **Linear** (the default interpolation method), **Piecewise cubic**, or **Cubic spline**.
 - **Nearest neighbor** interpolation selects the value of the nearest point where the function is defined.
 - **Linear interpolation** uses a linear polynomial to interpolate the function between the points where it is defined.
 - **Piecewise cubic** interpolation uses a piecewise-cubic Hermite polynomial with continuous first derivatives. It preserves the shape of the data and respects monotonicity.
 - The **Cubic spline** method also performs interpolation with a piecewise cubic polynomial. Here, even second derivatives are continuous; however, the method does not necessarily respect monotonicity.
- For functions of more than one variable, select **Nearest neighbor** or **Linear**. The other options are not supported.

Select an **Extrapolation** method to specify how to treat arguments outside the grid or mesh of points.

- **Constant**. Uses the value from the closest point inside the grid (for structured interpolation) or the value from the closest mesh element (for unstructured interpolation). The function evaluates the polynomial from the closest grid point at the actual point where a value is requested. This is the default extrapolation method.

For interpolation functions with three arguments, the Constant method will not reliably find the closest mesh element. It will find some point on the boundary of the interpolation mesh.

- **Linear**. The function is linear outside the grid with a continuous function value and continuous first derivative at the boundary of the grid. **Piecewise cubic** or **Cubic spline** must be selected from the **Interpolation** list.
- **Nearest function**. Evaluates the polynomial from the closest grid point at the actual point where a value is requested.
- **Specific value**. Uses a single value, such as zero or NaN (Not-a-Number), everywhere outside the grid or mesh. Enter the value in the **Values outside range** field.

Unstructured extrapolation supports a constant or a specific value only.

PLOT PARAMETERS

If you have selected to define the inverse function (see below), this section becomes available. Select the **Plot the inverse function** check box to plot the inverse function instead of the interpolation function itself when you click the **Plot** button () to generate a preview plot.

A plot group for an interpolation function contains three connected line graphs: a line graph of the piecewise function and two line graphs using dashed red lines, Left Extrapolation and Right Extrapolation, which show how the selected extrapolation extends the interpolation function on both sides. In addition, a point graph shows the interpolation points (interpolation nodes).

RELATED FUNCTIONS

In this section, you can define the following related functions:

Inverse Function

The inverse function is available for interpolation functions defined by a local table only. If you want to define the inverse function f^{-1} for the interpolation function f , select the **Define inverse function** check box and enter a function name for the inverse function in the **Inverse function name** field (the default is the name of the interpolation function with a suffix `_inv`). If you want to plot the inverse function instead of the interpolation function itself, first select the **Plot the inverse function** check box in the **Plot Parameters** sections, which is only available when you have chosen to define the inverse function.

The inverse function only exists if the function is strictly monotonic.

Primitive Function

If you want to define the primitive function F for the interpolation function f , select the **Define primitive function** check box and enter a function name for the primitive function in the **Primitive function name** field (the default is the name of the interpolation function with a suffix `_prim`). You can use the primitive function to sample from the interpolation function. The primitive function is the integral of the interpolation function. The integration constant is such that the value of the primitive function is zero at the first data point. In other words, if the interpolation function is $f(x)$, then the primitive function is

$$F(x) = \int_{x_0}^x f(y) dy$$

where x_0 is the x -coordinate of the first data point.

Random Function

To define a random function, select the **Define random function** check box with a name that you specify in the **Random function name** field (the default for an interpolation function `int1` is `rn_int1`). You can use this function to sample from the interpolation function. A random functions can be useful in particle tracing, for example.

Suppose, for example, that you want to specify an arbitrary energy distribution function for the initial energy of a bunch of particles. In order to do this, you need to randomly sample from an interpolation function, not merely call it. The random function makes this possible. To use a random function for this purpose, select the **Define random function** check box, and then call it in an Inlet feature, for example, using `rn_int1(cpt.pidx)`, where `cpt.pidx` is a variable that is uniquely valued for each particle.

The default number of arguments is 1. If you want to use additional arguments, type a number in the **Number of arguments** field.

You specify the range of the random function using the **Range** list. The default is **Automatic**. Choose **Manual** to provide limits in the **Lower limit** and **Upper limit** fields.

See [Common Settings for the Function Nodes](#) for information about the **Units** section.

MATLAB

A LiveLink™ for MATLAB® license is required. Also confirm that MATLAB® is installed on the same computer as COMSOL Multiphysics.

Use a **MATLAB** functions node () from COMSOL Multiphysics to interface to functions written in MATLAB. These functions can be used as any other function defined in COMSOL Multiphysics. MATLAB functions are evaluated in MATLAB.

FUNCTIONS

Under **Functions**, add the names of the MATLAB functions in the **Function name** column, and for each function in the table, enter a space-separated or comma-separated list of the names of its input **Arguments** (x y, for example).

Any function that you want to call using a MATLAB node must fulfill the following requirements:

- It can take any number of inputs as vectors and must return a single output vector.
- The input vectors can be of arbitrary size, but in a single call the inputs vectors must all have the same size. The returned vector must have exactly the same size as the input vectors.

For example, functions such as + and - (plus and minus) work well on vector inputs, but matrix multiplication (*, mtimes) and matrix power (^, mpower) do not. Instead, use the elementwise array operators .* and .^.

Click the **Clear Functions** button to force a reload of the functions if they have been edited or if you have changed the security preferences. Alternatively, you can select the **Clear functions automatically before solving** check box.

- Go to [Common Settings for the Function Nodes](#) for information about the **Derivatives** and **Plot Parameters** sections.
 - The *LiveLink™ for MATLAB® User's Guide*
-

Piecewise

A **Piecewise** function () is created by splicing together several functions, each defined on one interval. Define the argument, extrapolation and smoothing methods, and the functions and their intervals. The piecewise function

is a function of one variable with different definitions on different intervals, which must not overlap or have any holes between them. The default **Function name** is pw1.

The Analytic, Interpolation, and Piecewise functions can also be added to Materials. See [Using Functions in Materials](#).

DEFINITION

Enter a name for the argument to the piecewise function in the **Argument** field.

Select an **Extrapolation** method to control what happens when the function is evaluated in a point that does not belong to any interval: **Constant** (the default), **None**, **Nearest function**, **Specific value**, or **Periodic**.

- **Constant.** Uses the function value from the endpoint of the closest interval. Uses the value from the starting point of the first and the endpoint of the last interval on the corresponding sides.
- **None.** Evaluation fails outside of the intervals where it is defined. Trying to evaluate the function generates an error and evaluates to NaN (Not-a-Number).
- **Nearest function.** Evaluate the function from the closest interval. The function at the first or last interval (depending of the side) is used to evaluate at the actual point where a value is requested.
- **Specific value.** Also enter a value in the **Value outside range** field. If selecting the specific-number method, assign a single value (usually zero or NaN) to all points outside the intervals.
- **Periodic.** The function becomes periodic by repeating its values in the interval where it is defined in regular intervals of the same size.

Select a **Smoothing: No smoothing** (the default), **Continuous function** (to make the function continuous but not its derivatives), **Continuous first derivative**, or **Continuous second derivative**. For any selection (except **No smoothing**), enter a value in the **Size of transition zone** field (dimensionless). The default is 0.1. Using the **Transition zone** list you can select if the size should be relative or absolute. **Relative size** (the default) means that the size is relative in relation to the size of the intervals on both sides of the border. **Absolute size** gives smoothing on an interval that is symmetric around the border. If you have chosen to use smoothing and the **Extrapolation** is **Constant**, **Specific value**, or **Periodic**, a **Smooth at endpoints** check box appears. Select that check box if you want to smooth at the endpoints — that is, the left endpoint of the leftmost interval and the right endpoint of rightmost interval.

The functions in contiguous intervals need not evaluate to the same value where the intervals meet. If the values differ the function has a discontinuity, and it is recommended that you apply smoothing to make the piecewise function more well-behaved numerically. Functions from neighboring intervals are then blended close to where the intervals meet.

For each cell in the **Intervals** table, enter **Start** and **End** interval limits. The intervals must not overlap, and there cannot be any holes between intervals. Enter an expression defining the **Function**.

The intervals must be contiguous.

A plot group for a piecewise function contains three connected line graphs: a line graph of the piecewise function and two line graphs using dashed red lines, Left Extrapolation and Right Extrapolation, that show how the selected extrapolation extends the piecewise function on both sides.

See [Common Settings for the Function Nodes](#) for information about the **Units** section.

With the Heat Transfer Module, see *Radiative Heat Transfer in a Utility Boiler*: Application Library path **Heat_Transfer_Module/Thermal_Radiation/boiler**.

Ramp

A **Ramp** function () is a linear increase with a user-defined slope that begins at some specified time. The ramp function is a function of one variable (the time t , for example). The default **Function name** is `ramp1`.

- See [Function Names and Calling Functions](#) for information about the **Function name** section.
- See [Common Settings for the Function Nodes](#) for information about the **Smoothing** section.

PARAMETERS

Enter a **Location** value s_0 for the start of the ramp. The function evaluates to 0 for values less than its start location and increases linearly for values greater than the location.

If the **Smooth at start** check box is selected under **Smoothing**, then the **Ramp** function can become nonzero at some time before the location value. A model might not solve due to the possible inconsistencies between the ramp excitation and the initial condition (for example, the initial condition is zero, but the ramp function returns a small nonzero value at the starting time for the simulation).

Enter a **Slope** k (dimensionless) of the ramp. The default is 1.

To ensure that the value never exceeds a certain point, select the **Cutoff** check box and enter a value. The default is 1. For an input variable s , a start location s_0 , and a slope k , the ramp function's value is 0 for $s < s_0$ and $k(s - s_0)$ for $s \geq s_0$.

Random

A **Random** function () generates white noise with uniform or normal distribution and has one or more arguments to simulate white noise. Its distribution is either uniform or normal. The default **Function name** is `rn1`.

To generate a random function of the spatial coordinates x , y , and z , for example, use this function with three input variables; it returns the same value each time it is called for a given set of input arguments.

See [Function Names and Calling Functions](#) for information about the **Function name** section.

PARAMETERS

Enter a **Number of arguments** to the random function (the default is 1). Select a **Distribution** method: **Uniform** (the default) or **Normal**. If **Uniform** is selected, enter a **Mean** and **Range**. The default mean and range is 0 and 1, respectively. The range is the difference between the largest and smallest values that the function can return. If **Normal** is selected, enter a **Mean** and **Standard deviation**. The defaults are 0 and 1, respectively.

If you need to create several random functions that return independent random values, select the **Use random seed** check box and make sure that the functions have different random seeds in the **Random seed** field. By default, different random functions will have different random seeds. The random seed can also be used to do Monte Carlo simulations. Enter a parameter as random seed and let the parameter vary during a parametric sweep.

Rectangle

A **Rectangle** function () is 1 in an interval and 0 everywhere else. This function (also called top hat or boxcar) is useful for band-pass filtering; you can use it to select values within an interval. It can also simulate a signal that is turned on during an interval or a load that is active on a part of a boundary, for example. The rectangle function is a function of one variable (the time t , for example). The default **Function name** is `rect1`.

LIMITS

Enter a **Lower limit** (the default is -0.5) and **Upper limit** (the default is 0.5) to specify the interval for the rectangle function. For example, if the input argument is time, enter a start and end time. This function evaluates to 1 for values within the interval from the lower limit to the upper limit. Outside the interval it evaluates to 0.

- See [Function Names and Calling Functions](#) for information about the **Function name** section.
 - See [Common Settings for the Function Nodes](#) for information about the **Smoothing** section.
-

If you have the Batteries & Fuel Cells Module, see *Soluble Lead-Acid Redox Flow Battery*:
Application Library path **Batteries_and_Fuel_Cells_Module/Flow_Batteries/pb_flow_battery**.

Step

A **Step** function () is a sharp transition from 0 to some other value (amplitude) at some location (a certain time, for example). Create a single step function with a certain amplitude from an initial level to a final level at a start location. The step function is a function of one variable (the time t , for example). The default **Function name** is `step1`.

PARAMETERS

Enter a **Location** (s_0) for the start of the step. The value of the step function is the start level for input values that are smaller than the location of the step. In the **From** field, enter a start level (L_{start}). In the **To** field, enter a final level (L_{end}). For an input variable s , a start location s_0 , a start level L_{start} , and a final level L_{end} , the step function's value is L_{start} for $s < s_0$ and L_{end} for $s \geq s_0$. The amplitude of the step is $L_{\text{end}} - L_{\text{start}}$.

- See [Function Names and Calling Functions](#) for information about the **Function name** section.
 - See [Common Settings for the Function Nodes](#) for information about the **Smoothing** section.
-

Thermodynamics Property Package

COMSOL Multiphysics provides a **Property Package** feature (if a compliant thermodynamics property package of a supported type is installed) to enable the linking to external physical and thermodynamic property calculations for use in the Chemical Reaction Engineering Module.

For more information see the *Chemical Reaction Engineering Module User's Guide*.

Triangle

A **Triangle** function () is a linear increase and linear decline within an interval and 0 everywhere else. You can use the triangle function for band-pass filtering, for example; that is, use it to select values within an interval. The triangle function is a function of one variable (the time t , for example). The default **Function name** is `tri1`.

PARAMETERS

Enter a **Lower limit** (the default is -0.5) and **Upper limit** (the default is 0.5) to specify the interval for the triangle function. For example, if the input argument is time, enter a start and end time. In the midpoint of the interval, this function evaluates to 1, and moving toward the interval boundaries it falls off to 0. Outside the interval it evaluates to 0.

- See [Function Names and Calling Functions](#) for information about the **Function name** section.
- See [Common Settings for the Function Nodes](#) for information about the **Smoothing** section.

Waveform

A **Waveform** function () is a periodic function with one of several characteristic shapes: sawtooth, sine, square, or triangle. The waveform function is a function of one variable (the time t , for example). The default **Function name** is `wv`.

See [Function Names and Calling Functions](#) for more information about the **Function name** section.

PARAMETERS

Select a waveform **Type: Sawtooth, Sine** (the default), **Square**, or **Triangle**. For any selection, enter **Angular frequency** (default is 1), **Phase** (unit: radians; the default is 0), and **Amplitude** (default is 1) values. For the **Square** and **Triangle** waveforms, you can also specify the **Duty cycle** (the ratio between the pulse duration and the period). The default value is 0.5. The duty cycle is the fraction (that is, a value between 0 and 1) of a period in which the function has the high value (for a Square waveform) or for which the function is rising (for a Triangle waveform).

With the Batteries & Fuel Cells Module, see *1D Lithium-Ion Battery for Thermal Models*: Application Library path `Batteries_and_Fuel_Cells_Module/Thermal_Management/li_battery_Id_for_thermal_models`.

Specifying Discontinuous Functions

To specify a discontinuous function, such as a step in space or time, you can use logical functions that evaluate to 1 if true and 0 otherwise. For instance, the following function defines a sine wave that exists for 10 seconds and afterward takes the value 0:

```
sin(2*pi*t)*(t<10)
```

If a coefficient or a material property contains a step function or some other discontinuity, convergence problems can arise. For time-dependent problems, the time-stepping algorithm can run into problems. For stationary problems, mesh-resolution issues can arise such as overshooting or undershooting of the solution due to infinite flux problems. To avoid problems with a discontinuity, replace it with a smoothed step function that emulates steps. Doing so serves two purposes:

- Numerical reliability and convergence are improved.
- What is thought of as a step function is, in reality, a smoothed continuous function because of inertia.

SMOOTHING OF DISCONTINUOUS FUNCTIONS

The easiest way to create a smooth step is to use the predefined Step function. It includes smoothing by default. The Piecewise, Ramp, Rectangle, and Triangle functions also include smoothing (active by default for Rectangle and Triangle functions). Smoothed Step and Rectangle functions are defined by piecewise 5th-degree polynomials, smoothed Ramp functions by piecewise 4th-degree polynomials, and smoothed Triangle functions by piecewise 3rd-degree polynomials. None of these functions have any overshoot or undershoot.

ADDITIONAL SMOOTHED FUNCTIONS

In addition, the following smoothed functions are available:

- **f1smhs**, a smoothed step function, or *Heaviside function*, with a continuous first derivative and overshoot on both sides of the step. The overshoot ensures that the integral from 0 to infinity is correct. $y=f1smhs(x, scale)$ approximates the logical expression $y = (x>0)$ by smoothing the transition within the interval $-scale < x < scale$; that is, the scale value is half of the smoothing zone s . **f1dsmhs** is the derivative of the smoothed Heaviside function.
- **f1smsign**, a smoothed sign function with a continuous first derivative. $y = f1smsign(x, scale)$ approximates the function $y = \text{sign}(x)$ by smoothing the transition within the interval $-scale < x < scale$. **f1dsmsign** is the derivative of the smoothed sign function.
- **f1c1hs**, a smoothed Heaviside function with a continuous first derivative without overshoot. Its syntax is similar to the functions just described. The definition of **f1c1hs** is the following:
 - $f1c1hs(x, d) = 0$, if $x \leq -d$
 - $f1c1hs(x, d) = 1$, if $x \geq d$
 - $f1c1hs(x, d) = 0.5 + 0.75 \cdot (x/d) - 0.25 \cdot (x/d)^3$
- **f1c2hs**, a smoothed Heaviside function with a continuous second derivative without overshoot. Its syntax is similar to the functions just described. The definition of **f1c2hs** is the following:
 - $f1c2hs(x, d) = 0$, if $x \leq -d$
 - $f1c2hs(x, d) = 1$, if $x \geq d$
 - $f1c2hs(x, d) = 0.5 + 0.9375 \cdot (x/d) - 0.625 \cdot (x/d)^3 + 0.1875 \cdot (x/d)^5$

To create a smoothed rectangle over an interval $[a, b]$ with one continuous derivative and a smoothing zone s , use $f1c1hs(x-a, 0.5*s) - f1c1hs(x-b, 0.5*s)$. Similarly, you define a smoothed rectangle over an interval $[a, b]$ with two continuous derivatives and a smoothing zone s using $f1c2hs(x-a, 0.5*s) - f1c2hs(x-b, 0.5*s)$.

These functions can be useful as a complement and extension to the predefined Step function. In the interval $\text{scale} < x < \text{scale}$, the functions `f1smhs` and `f1smsign` are defined by a 7th-degree polynomial chosen so that the 2nd derivative is continuous. Moreover, the moments of order 0, 1, and 2 agree with those for the Heaviside function and the sign function, respectively. This implies that the functions have small overshoots.

Now consider an example. Use `f1c1hs` to model the heat capacity C_p of a phase-changing material. Assume that a crystalline material has a heat capacity of 1 kJ/kg. Its melting point at the present pressure is 273.15 K. The liquid phase has a heat capacity of 2 kJ/kg. Create a parameter `scale` with a value of 0.1 and then an **Analytic** node where an analytic function `HeatCapacity` is defined using the following expression with an argument $T: 1+f1c1hs(T - 273, \text{scale})$; then define a plot range of 272.5–273.5 K under **Plot Parameters** and click the **Plot** button in the **Settings** window for **Analytic** to plot C_p around the melting point.

Matrices and Matrix Operations

In a component, you can define matrices and matrix operations such as matrix inverse and matrix diagonalization. The resulting matrices, as well as the input matrices, become available for use in equation and postprocessing in the form of scalar variables with a common base name and an indexing convention. The following sections describe the utility nodes for defining matrices and matrix operations.

Matrix

Add a **Matrix** node (**A**) under **Definitions>Variable Utilities** (if **Group by Type** is active; otherwise, directly under **Definitions**) to define a square matrix of variables. You add it by right-clicking the **Definitions** node and choosing **Variable Utilities>Matrix** or by right-clicking the **Variable Utilities** node and choosing **Matrix**.

You can define a **Label** for the node and a base **Name** for the matrix. For the **Geometry Entity Selection**, see [About Selecting Geometric Entities](#).

In addition, the **Settings** window for a **Matrix** node contains the following section:

INPUT MATRIX

Choose a **Matrix format: Full** (the default), **Symmetric**, or **Hermitian**. For a symmetric or Hermitian matrix, you only enter the upper-triangular part of the matrix. A Hermitian matrix (or self-adjoint matrix) is a complex square matrix that is equal to its own conjugate transpose. From the **Matrix size** list, choose a matrix size from 1x1 to 9x9; then enter the matrix elements in the table below.

The matrix is available as a list of variables with names $\langle\text{name}\rangle\langle i\rangle\langle j\rangle$, where $\langle\text{name}\rangle$ is the namespace set in the **Name** field, and $\langle i\rangle$ and $\langle j\rangle$ are integer indices. You can use individual components where variable expressions are allowed, but also evaluate all variables at once using a matrix evaluation node under **Derived Values**. For example, select **T1** under **Model>Component 1>Definitions>Matrix variables**, if the matrix has been defined with the name **T1** in **Component 1**.

Matrix Inverse

Add a **Matrix Inverse** node (**A⁻¹**) under **Definitions>Variable Utilities** (if **Group by Type** is active; otherwise, directly under **Definitions**) to define a variable as the inverse of a square input matrix. You add it by right-clicking the **Definitions** node and choosing **Variable Utilities>Matrix Inverse** or by right-clicking the **Variable Utilities** node and choosing **Matrix Inverse**.

You can define a **Label** for the node, and a namespace for variables using the **Name** field. For the **Geometry Entity Selection**, see [About Selecting Geometric Entities](#).

In addition, the **Settings** window for a **Matrix Inverse** node contains the following section:

INPUT MATRIX

In this section, you define the input matrix to invert. Choose a **Matrix format: Full** (the default), **Symmetric**, or **Hermitian**. For a symmetric or Hermitian matrix, you only enter the upper-triangular part of the matrix. A Hermitian matrix (or self-adjoint matrix) is a complex square matrix that is equal to its own conjugate transpose. From the **Matrix size** list, choose a matrix size from 1x1 to 9x9; then enter the matrix elements in the table below.

The resulting matrix inverse is available as a list of scalar variables with names $\langle\text{name}\rangle.\text{invT}\langle i\rangle\langle j\rangle$, where $\langle\text{name}\rangle$ is the namespace set in the **Name** field, and $\langle i\rangle$ and $\langle j\rangle$ are integer indices. The input matrix with names $\langle\text{name}\rangle.\text{T}\langle i\rangle\langle j\rangle$, as well as the matrix determinant $\langle\text{name}\rangle.\text{detT}$ are also made available. Note that the determinant is not computed for matrices of size 4x4 or larger; if required, use a **Matrix Decomposition** node instead.

You can use individual components where variable expressions are allowed, but also evaluate all variables at once using a matrix evaluation node under **Derived Values**. For example, select **matinv1.invT** under **Model>Component I>Definitions>Matrix Inverse I>Matrix inverse** if it the node has been defined as **Matrix Inverse I** with the name **matinv1** in **Component I**.

Matrix Diagonalization

Add a **Matrix Diagonalization** node ( ^{ADA¹}) under **Definitions>Variable Utilities** (if **Group by Type** is active; otherwise, directly under **Definitions**) to define variables for the diagonalization of a symmetric 3x3 input matrix. You add it by right-clicking the **Definitions** node and choosing **Variable Utilities>Matrix Diagonalization** or by right-clicking the **Variable Utilities** node and choosing **Matrix Diagonalization**.

You can define a **Label** for the node, and a namespace for variables using the **Name** field. For the **Geometry Entity Selection**, see [About Selecting Geometric Entities](#).

In addition, the **Settings** window for a **Matrix Diagonalization** node contains the following sections:

INPUT MATRIX

Enter the symmetric matrix elements for the 3x3 input matrix in the table. The matrix diagonalization is primarily intended for extracting principal components of 3D tensor quantities such as principal stresses and strains.

OUTPUT

Select the **Compute exponential** check box to compute also the matrix e^T , where **T** is the input matrix.

Select the **Ignore Jacobian contributions** check box (selected by default) to ignore any solution dependencies during the solution process.

The principal values become available as variables $<\text{name}>.\text{e}<\text{i}>$, where $<\text{name}>$ is the namespace set in the **Name** field, and $<\text{i}>$ is the principal component index, ordered from largest to smallest absolute value. Components of the corresponding principal vectors are called $<\text{name}>.\text{e}<\text{i}><\text{j}>$, where $<\text{j}>$ are integer indices. If **Compute exponential** was selected, the result can be evaluated as a list of variables with names $<\text{name}>.\text{expT}<\text{i}><\text{j}>$. The input matrix with names $<\text{name}>.\text{T}<\text{i}><\text{j}>$, as well as its determinant $<\text{name}>.\text{detT}$ are also made available. Note that the determinant is not computed for matrices of size 4x4 or larger; if required, use a **Matrix Decomposition** node instead.

You can use individual components where variable expressions are allowed, but also evaluate complete vectors and matrices at once using a matrix evaluation node under **Derived Values**. For example, to evaluate the first principal vector, select **matdiag1.e1_vec** under **Model>Component I>Definitions>Matrix Diagonalization I>Principal vector I** if it the node has been defined as **Matrix Diagonalization I** with the name **matdiag1** in **Component I**.

Matrix Decomposition (SVD)

Add a **Matrix Decomposition (SVD)** node ( ^{UV*}) under **Definitions>Variable Utilities** (if **Group by Type** is active; otherwise, directly under **Definitions**) to define variables for a decomposition using SVD (*singular value decomposition*) of a square input matrix. You add it by right-clicking the **Definitions** node and choosing **Variable Utilities>Matrix Decomposition (SVD)** or by right-clicking the **Variable Utilities** node and choosing **Matrix Decomposition (SVD)**.

You can define a **Label** for the node, and a namespace for variables using the **Name** field. For the **Geometry Entity Selection**, see [About Selecting Geometric Entities](#).

In addition, the **Settings** window for a **Matrix Decomposition (SVD)** node contains the following sections:

INPUT MATRIX

Choose a **Matrix format: Full** (the default) or **Symmetric**. For a symmetric matrix, you only enter the upper-triangular part of the matrix. From the **Matrix size** list, choose a matrix size from 1x1 to 9x9; then enter the matrix elements in the table below.

OUTPUT

The **Matrix Decomposition (SVD)** node can compute two different decompositions of the input matrix. The basic singular value decomposition (SVD)

$$T = U\Sigma V^*$$

splits the matrix as a product of a unitary matrix **U** (with left singular vectors as columns), a diagonal matrix **Σ** (with positive singular values on the diagonal), and the conjugate transpose of a unitary matrix **V** (with right singular vectors as columns). From the SVD, also a *polar decomposition*

$$T = RP$$

can be computed, where **R** is a unitary rotation matrix and **P** is a positive definite stretch matrix.

The node always computes the singular values, which are made available as variables `<name>.sigma<i>`, where `<name>` is the namespace set in the **Name** field, and `<i>` is the singular value index, ordered from largest to smallest. The input matrix with names `<name>.T<i><j>`, as well as the matrix determinant `<name>.detT` are also always defined.

In addition, all the following check boxes are selected by default to provide the corresponding matrices and vectors as output.

- Select the **Compute left singular vectors** check box to compute the left singular vectors and define corresponding variables `<name>.U<i><j>`, where index `<i>` corresponds to rows in the input matrix and `<j>` are principal value indices.
- Select the **Compute right singular vectors** check box to compute the right singular vectors and define corresponding variables `<name>.V<i><j>`, where index `<i>` corresponds to columns in the input matrix and `<j>` are principal value indices.
- Select the **Compute rotation matrix** check box to compute the *rotation matrix* and define corresponding variables `<name>.R<i><j>`, where index `<i>` corresponds to rows in the input matrix and `<j>` corresponds to columns.
- Select the **Compute stretch matrix** check box to compute the *stretch matrix* and define corresponding variables `<name>.P<i><j>`, where indices `<i>` and `<j>` corresponds to columns in the input matrix.

You can use individual components where variable expressions are allowed, but also evaluate complete vectors and matrices at once using a matrix evaluation node under **Derived Values**. For example, to evaluate the complete matrix of right singular vectors, select **matdec1.V** under **Model>Component 1>Definitions>Matrix Decomposition (SVD) 1>Right singular vectors** if the node has been defined as **Matrix Decomposition (SVD) 1** with the name **matdec1** in **Component 1**.

Component Couplings and Coupling Operators

About Component Couplings

Component couplings establish couplings between different parts of a model component or between different model components. A component coupling is defined by a *coupling operator*, taking an expression as its argument when you use it (for example, to compute an average concentration). When the operator is used at a point in the destination geometry, for example, the value is computed by evaluating the argument in the source geometry. You can use a coupling operator to compute several quantities that use the same type of coupling between a source and a destination by calling it with different arguments. All types of component couplings have a source and a destination.

Scalar coupling operators, such as the Integration coupling operator, have a global destination that does not need to be defined; the values are available globally.

The *source* is a subset of a single model component (such as some domains or boundaries) where the coupling operator evaluates the supplied expression (as an integration over the source, for example), while the *destination* is the part of the geometry where the result of the coupling operator is defined. The destination can, depending on the type of coupling, be a subset of one or several model components or a “global destination” (for a scalar value that is available everywhere). The coupling operator’s value is computed by evaluating the expression given as an argument at one or several points in the source. The source and destination are both geometrical objects, but the source is limited to a single geometry, or a part of a single geometry, whereas the destination is often global.

To add a Component Coupling to any Component:

- In the **Definitions** toolbar, select a component coupling node from the **Component Couplings** menu, or
- Right-click the **Definitions** (≡) node and choose an option from the **Component Couplings** submenu.

ABOUT COUPLING OPERATORS

Coupling operators are useful for modeling problems with multiple components that are connected, for example. They represent generalizations of expressions that can simplify a problem and thereby reduce the computational cost and time. You define a coupling operator by first selecting the source, where the argument of the operator is evaluated, and, in some cases, a destination. An expression to evaluate is not required when you define a coupling operator; instead you can use coupling operators in different modeling contexts, passing the expression to evaluate as an input argument to the coupling operator.

There are three categories of coupling operators:

- *Extrusion*. These operators — [General Extrusion](#), [Linear Extrusion](#), [Boundary Similarity](#), and [Identity Mapping](#) — connect a source and a destination and take an expression as an argument. When the argument is evaluated at a point in the destination, its value is computed by evaluating the argument at a corresponding point in the source. When the source and destination are of the same space dimension, it is typically a pointwise mapping. When the destination has a higher dimension than the source, the mapping is done by extruding pointwise values to the higher dimensions. For some examples of the use of extrusion coupling operators, see [Examples of Extrusion Couplings](#).
- *Projection*. These operators — [General Projection](#) and [Linear Projection](#) — evaluate a series of line or curve integrals on the source, where the line or curve positions depend on the positions of the evaluation points in the destination. In this way it is possible to compute the integral of an expression over one space variable for a range of different points along the other space axis, giving a result that varies over the latter space variable. For example,

you can obtain the average along the y direction of a variable u defined on some 2D domain in the xy -plane by computing the integral

$$\bar{u}(x) = \int u(x, y) dy$$

You can compare the projection couplings to creating a 2D projection as a shadow on a wall using lighting on a 3D object. COMSOL Multiphysics uses a method whereby it first applies a one-to-one map to the mesh of the source. It then carries out the integrals in the source over curves that correspond to vertical lines in the transformed source mesh. You can define the map between source and destination in two ways: as a *linear projection* or as a *general projection*. For some examples of the use of projection coupling operators, see [Examples of Projection Couplings](#).

The projection coupling does not project the `srdim`-dimensional source onto the destination; it projects the source onto the `srdim-1` lowest dimensions of the intermediate mesh, from which results are fetched using the destination transformation. Any domain where the destination transformation can be evaluated is a valid destination; the destination's topology is not related to the projection process in any way, except for the constraint that the destination transformation it must map the destination points into the region of `srdim-1`-dimensional space where there is any data to fetch.

- *Scalar*. These operators — [Integration](#), [Average](#), [Maximum and Minimum](#) — define a scalar value such as an integration, the average over a set of geometric entities, or the maximum or minimum value of an expression and have a “global destination” (that is, they are available everywhere in the model) that you do not need to specify:
 - An *Integration coupling operator* is the value of an integral of an expression over the source, which is a set of geometric entities (domains, for example).
 - An *Average coupling operator* computes the average of an expression over the source.
 - A *Maximum* or *Minimum coupling operator* computes the maximum or minimum, respectively, of an expression over the source.

These operators can be evaluated anywhere in a model, and the value does not depend on where in the model the evaluation occurs. Integration couplings are useful for evaluating integrated quantities. To evaluate the total current across a boundary in a 2D Electric Currents model, for example, define an integration coupling operator `intop1` with a source on the boundary where the current flows. Then the value of `intop1(ec.normJ*ec.d)`, where `normJ` is the current density norm (SI unit: A/m^2) and `d` is the thickness of the 2D geometry (SI unit: m), is the total current flowing across that boundary (SI unit: A). For some other examples of the use of integration coupling operators, see [Examples of Integration Couplings](#)

Coupling operators can:

- Make the value and the exact Jacobian of an expression available nonlocally.
- Take information from a domain, for example, and make it available on other parts of a model (a boundary, for example).
- Be used for results evaluation and visualization purposes.
- Define nonlocal couplings including mesh transformations, integrals over domains and boundaries, and projections.

ABOUT SOURCE AND DESTINATION MAPPINGS

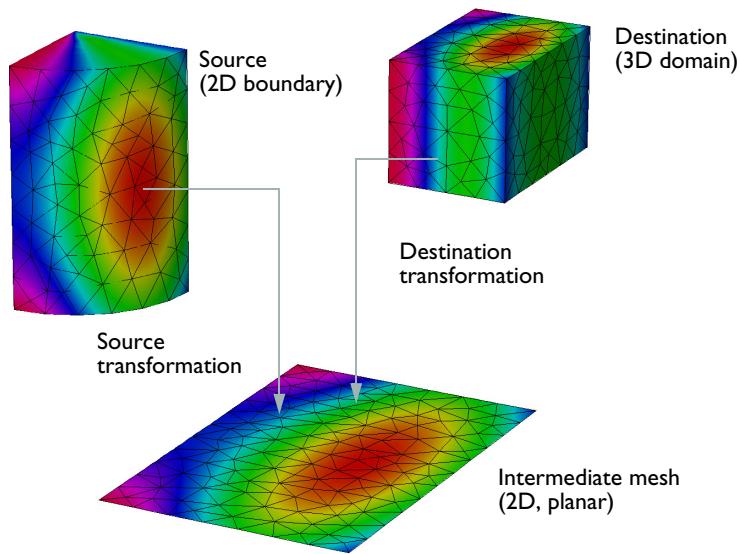

Figure 5-2: An example of a general extrusion mapping.

The definition of any extrusion coupling involves two mesh maps. The *source map* is a one-to-one mapping that maps the mesh of the physical source of dimension `srdim` to an *intermediate mesh* of the same dimension embedded in a space of dimension `idim` \geq `srdim`. The *destination map* is a mapping from the destination of dimension `dstdim`, where the operator can be evaluated, to the same space that contains the intermediate mesh.

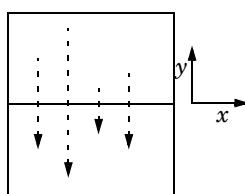

When the value of the coupling operator is requested somewhere in the destination, the software transforms the destination points using the destination map. It compares the resulting coordinates to the elements in the intermediate mesh to find corresponding locations in the physical source. This means that the source map must be inverted but not the destination map. The latter can in fact be noninvertible, which is, for example, the case when $dstdim > idim$, leading to an extrusion. If the mapping fails, select the **Use NaN when mapping fails** check box in the **Advanced** section of the **Settings** window for the **General Extrusion** and **Linear Extrusion** operators to evaluate the operator to NaN (Not-a-Number). Otherwise, an error occurs.

To avoid the need to solve a nonlinear system of equations for every destination point, the COMSOL Multiphysics software assumes that the source map is linear on each element of the intermediate mesh. In practice, the map is often trivial and leaves the coordinates unchanged, but it can also rescale, stretch, bend, or reflect the mesh.

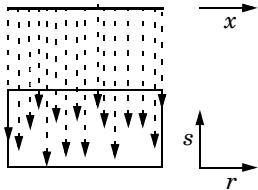

EXAMPLES OF EXTRUSION COUPLINGS

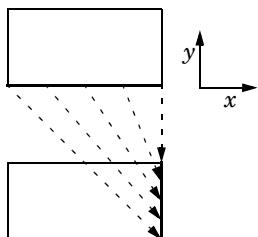

All the graphics in these examples use **General Extrusion** component coupling.

One application of a **General Extrusion** coupling is to mirror the solution on the x -axis. This can be useful for analysis; for example, to probe the solution at a point that is moving in time but is associated with a stationary geometry. Both source and destination are two-dimensional, as well as the intermediate mesh ($srdim = idim = dstdim$). The source map is x, y (which is the default source map) and the destination map to enter is $x, -y$. This can also be done with a **Linear Extrusion** coupling operator.

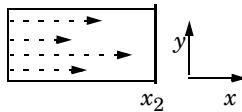

Another **General Extrusion** example is to extrude the solution in the 1D geometry to a 2D domain along the s -axis. The source map is x , and the destination map is r , so here $srdim = idim = 1$, $dstdim = 2$. If the 2D geometry is Component 1 (`comp1`) and the 1D geometry is Component 2 (`comp2`), you can plot the extruded 1D solution in a 2D surface plot using `comp2.genext1(u)`, for example, if the solution variable for the 1D solution is u .

Another example maps values on the lower boundary of a rectangle that extends from $x = -1$ to $x = 1$ and from $y = 0$ to $y = 1$, to the right boundary on the same rectangle. The source map can be the default x, y and the destination map then $2*y - 1, 0$; alternatively, you can set the source map to x and leave the y -expression empty, and the destination map as $2*y - 1$ and also leave the y -expression empty. Both maps have a single component because $srdim = idim = dstdim$. The difference between the first and second option is in which dimension the interpolation is performed (that is, the value of $idim$). The first option has the advantage that it can handle also source selections with a topology that cannot be represented in the dimension of the destination — for example, a map from a unit circle onto a line with source map x, y and destination map $\cos(x), \sin(x)$. The second option has the advantage that 1D interpolation is faster and does not risk interpolation failure for coarse and non-matching meshes. This map is also linear and can be done with **General Extrusion** or **Linear Extrusion**, or with **Boundary Similarity**.

Finally, consider the case of a single rectangular domain where the source term in Poisson's equation comes from the inward flux over the right boundary for the corresponding y coordinate.

$$\begin{aligned} -\Delta u &= \frac{\partial}{\partial n} u(x_2, y) && \text{on } \Omega \\ u &= xy && \text{on } \partial\Omega \end{aligned}$$

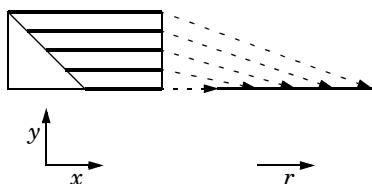

The figure to the left illustrates the extrusion process. The values of the influx on the boundary become available throughout the domain by extrusion along the y -axis. The source map is y , and the destination map is y .

EXAMPLES OF PROJECTION COUPLINGS

All these examples use the **General Projection** component coupling, but they can also be done using **Linear Projection** component couplings.

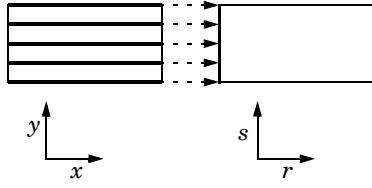

Projection Coupling — Example 1

For each point r , the coupling operator returns the integral

$$v(r) = \int_{y=r/2}^{y=r} u(x, y) dx$$

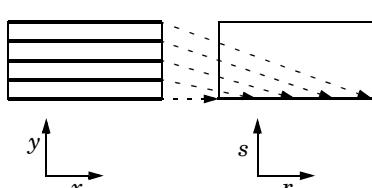

The source map is y, x , and the destination map is $r/2$.

For each point $(0, s)$, the coupling operator returns the integral

$$v(0, s) = \int_{\substack{y=s \\ (x,y) \in S_2}} u(x, y) dx$$

The source map is y , x , and the destination map is s .

For each point $(r, 0)$, the coupling operator returns the integral

$$v(r, 0) = \int_{\substack{y=r/2 \\ (x,y) \in S_2}} u(x, y) dx$$

The source map is y , x , and the destination map is $r/2$.

For example, if the 2D geometry is Component 1 (`comp1`) and the axisymmetric 2D geometry is Component 2 (`comp2`), you can plot the projected 2D solution in a 2D axisymmetric line plot using `comp1.genproj(u)`, for example, if the solution variable for the planar 2D solution is `u`.

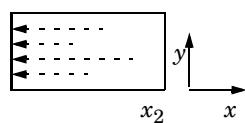

The integration can also sweep nonrectangular domains. The integrals include only the source domains; they exclude other domains and the external area.

Projection Coupling — Example 2

Consider the case of a single rectangular domain with Poisson's equation. Integrate the solution squared along lines parallel to the x -axis and make the result available for analysis on the left boundary.

$$\begin{aligned} -\Delta u &= 1 && \text{on } \Omega \\ u &= 0 && \text{on } \partial\Omega \end{aligned}$$

The figure illustrates the projection process. Project the integral of the solution squared on the boundary. The source map is y , x and the destination map is y . If the projection operator is called `genproj1`, the desired result is obtained by evaluating `genproj1(u^2)`.

Projection Coupling — Example 3

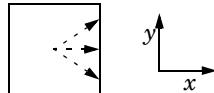

Consider a cylinder with a radius R in the xy -plane and a height L in the z direction. For the solution u in this geometry, the following two examples describe two type of projections:

- On one quarter of the side of this cylinder, you want to integrate the solution along curved lines of the cylinder and project it onto a straight line $z = [0, L]$. The source map is then z , $\text{atan2}(y, x)$, and you leave the z -expression empty. That creates a rectangular source where the x -axis is the z -coordinate and the y -axis is the angle along the side of the cylinder, which is the direction in which you want to integrate the solution for every position along the z -axis. The destination map here is simply z (leave the y -expression empty). The integral of the solution u along the side of the cylinder is available as, for example, `genproj1(u)`. To normalize it taking the length of

the curved lines into account, use `genproj1(u)/(R*pi/2)` or `genproj1(u)/genproj1(1)`, where the latter expression also gives the length of the curved lines.

- It is also possible to do a projection with the cylindrical domain as the source and a boundary as target: For example, projecting the integral of u along the z -direction onto the bottom surface of the cylinder. To do so, create a General Projection coupling operator (`genproj2`, for example) with the default source map — x, y, z — and the default destination map: x, y . You can then plot and evaluate the projection of the integrated solution as a 2D plot on the bottom surface using `genproj2(u)`. To get the average value, divide the projected value by the height of the cylinder using `genproj2(u)/L` or `genproj2(u)/genproj2(1)`.

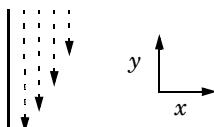

EXAMPLES OF INTEGRATION COUPLINGS

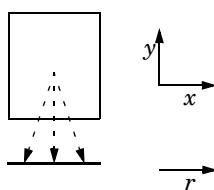

Consider Poisson's equation on a rectangular domain. The integral of the solution squared serves as the influx in a Neumann boundary condition on the right boundary. There is a Dirichlet boundary condition on the left boundary, and the top and bottom boundaries have zero influx.

$$\begin{aligned} -\Delta u &= 1 && \text{on } \Omega \\ u &= x && \text{on } \partial\Omega_1 \\ \frac{\partial u}{\partial n} &= 0 && \text{on } \partial\Omega_{2,3} \\ \frac{\partial u}{\partial n} &= -\int_{\Omega} u^2 d\Omega && \text{on } \partial\Omega_4 \end{aligned}$$

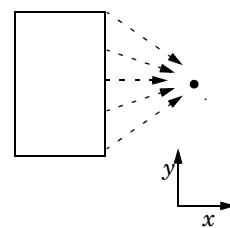

For example, define an integration coupling operator called `inttop1`, with the rectangular domain as source. You then define the influx for the Neumann boundary condition as `inttop1(u^2)`.

A second example is when a scalar value from a vertex is used everywhere on a boundary to which the vertex belongs. In structural mechanics you can use this type of coupling to formulate displacement constraints along a boundary in terms of the displacements of the endpoint. In electromagnetics the same technique can implement *floating contacts*.

Another example is to use the integral over a domain in a 2D geometry along a domain in another 1D geometry. This approach is helpful for process-industry models where two processes interact.

Integration coupling operators can implement *integral constraints*. First define a coupling operator at some vertex in such a way that it represents the value of the integral to be constrained. Then use a point constraint to set the coupling operator, and thereby the integral, to the desired value.

NONLOCAL COUPLINGS AND THE SPARSITY OF THE JACOBIAN

The Jacobian for problems formulated using the finite element method is usually large but sparse. This is because the solution at each mesh node can depend at most on the degrees of freedom at the neighboring mesh elements. However, by introducing nonlocal component couplings using coupling operators, nonlocal dependencies are created that fill up the rows and columns of the affected source and destination nodes. These additional elements might make the Jacobian matrix only slightly less sparse, with marginal effects on solution speed; they can also make it a great deal less sparse, in which case memory use and CPU time involved in solving the problem increases considerably. For this reason, take particular care when introducing nonlocal couplings. For example, defining a heat source based on an integration operator over the whole domain that is also a function of temperature (the dependent variable) leads to a coupling between all the degrees of freedom in the model creating a full Jacobian matrix instead of the sparse limited-bandwidth matrices typical of finite element models.

You can prevent the fill-in of the Jacobian matrix using the `nojac` operator, which forces COMSOL Multiphysics to exclude the expression that it encloses when forming the Jacobian. Using the `nojac` operator can slow down the convergence of the solution. Another possible solution is to add a single degree of freedom that represents the value of an expression with a scalar coupling operator.

General Extrusion

A **General Extrusion** coupling operator () maps an expression defined on a source to an expression that can be evaluated on any destination geometry where the destination map expressions are valid. Compared to the *linear extrusion*, these operators define a more general, possibly nonlinear, relation between source and destination. Specifically, when the destination has more space dimensions than the source, the operator performs extrusion of values. The default **Operator name** is `genext1`.

Go to [Common Settings for Component Couplings](#) for information about the **Operator Name**, **Source Selection**, **Source**, and **Advanced** sections.

DESTINATION MAP

Specify the general extrusion destination map by entering an expression in the **x-expression**, **y-expression**, and **z-expression** fields. This maps each point in the destination to a point in the intermediate mesh, where the argument of the extrusion operator is evaluated. A general extrusion operator can be evaluated at any point where the destination map expressions are defined.

The number of destination map expressions is the same as the space dimension of the intermediate mesh. For example, if the intermediate mesh is in 2D space, there is no **z-expression** field. Also, depending on the dimension of the coupling, you can leave the **y-expression** field in the source and destination maps empty for a 1D map in a 2D model component, for example.

If you have the:

- Acoustics Module, see *Flow Duct*: Application Library path **Acoustics_Module/Aeroacoustics_and_Noise/flow_duct**.
- Chemical Reaction Engineering Module, see *Packed Bed Reactor*: Application Library path **Chemical_Reaction_Engineering_Module/Reactors_with_Porous_Catalysts/packed_bed_reactor**.
- Geomechanics Module, see *Concrete Beam With Reinforcement Bars*: Application Library path **Geomechanics_Module/Tutorials/concrete_beam**.
- Subsurface Flow Module, see *Aquifer Characterization*: Application Library path **Subsurface_Flow_Module/Fluid_Flow/aquifer_characterization**.

Linear Extrusion

A **Linear Extrusion** coupling operator () maps an expression defined on a source to an expression that can be evaluated in the destination. Use this to define a linear mapping of this kind. Linear extrusion can be used when the correspondence between evaluation points in the source and destination is linear and in some nonlinear cases. Otherwise, use a general extrusion coupling. The Linear Extrusion operator defines a linear extrusion that maps between geometric parts of the same dimension. The parts can exist in geometries of different space dimensions. For example, you can couple edges (boundaries) in 2D to edges in 3D; or couple 2D domains to 3D faces. In these cases geometries of different space dimensions are needed for the source and destination. You define the linear extrusion by specifying points in both source and destination. The default **Operator name** is `linext1`.

Go to [Common Settings for Component Couplings](#) for information about the **Operator Name**, **Source Selection**, **Source Vertices**, **Destination Vertices**, and **Advanced**, sections.

DESTINATION

The mapping from destination to source is defined as the following:

- First, the destination is orthogonally projected onto the linear space spanned by the destination vertices.
- Then this linear space is mapped linearly to the source, so that each destination vertex is mapped to the corresponding source vertex.

Select an option from the **Destination geometry** list if there is more than one geometry in the model. A linear extrusion operator can only be evaluated on the destination geometry and the destination vertices must be chosen in the destination geometry. Select an option from the **Destination frame** to evaluate the destination vertex coordinates in the specified frame.

- With the Electrochemistry Module, see *Desalination in an Electrodialysis Cell*: Application Library path **Electrochemistry_Module/Electrochemical_Engineering/electrodialysis**.

Boundary Similarity

The **Boundary Similarity** coupling operator () maps an expression defined on a part of a boundary to another part of a boundary with the same shape. This operator is slightly different for 2D and 3D models:

- In 3D, the destination map is a similarity that maps a destination boundary onto a set of source boundaries. The mesh is always viewed in the geometry frame. By default, the algorithm automatically chooses a map when

symmetries make several maps possible. To control this choice in 3D, add a **One-Point Map** () , **Two-Point Map** () , or **Edge Map** subnode ().

- **Edge Map:** Specify that a certain destination edge should be mapped onto a certain source edge. The edge's relative direction is given by the property direction. The edges must be adjacent to the given boundary.
- **One-Point Map:** Specify that a certain destination vertex should be mapped onto a certain source vertex.
- **Two-Point Map:** Specify that two destination vertices should be mapped onto two source vertices.
- In 2D, it works the same except the destination map is a similarity that maps a destination edge onto a set of source edges and there are no subnodes to add.

The default **Operator name** is bndsim1.

Go to [Common Settings for Component Couplings](#) for information about the **Operator Name**, **Source Boundaries** and **Destination Boundary** sections, as well as the rest of the **Advanced**, section.

ADVANCED

For 2D models, select a relative **Direction** of the source and destination edges: **Automatic orientation** (the default), **Same orientation**, or **Opposite orientation**. This specifies the relative direction of the source and boundary edges and specifies which one of the two possible similarity mappings between the source and destination edge to use.

For 3D models, a similar direction functionality is provided by the subnodes **One-Point Map**, **Two-Point Map**, and **Edge Map** to exactly specify the similarity mapping between the source and destination when more than one possibility exists.

Select the **Use source map** check box to have a nonlinear correspondence between the source and destination. The source map is specified by entering expressions in the **x-expression**, **y-expression**, and **z-expression** fields.

Only one map node is allowed per boundary similarity coupling and only one source or destination point per field is allowed.

One-Point Map

Use a **One-Point Map** to control a **Boundary Similarity** component coupling mapping in 3D. Right-click the **Boundary Similarity** node to add a **One-Point Map** subnode ().

POINTS

To select a single **Point on source** and a single **Point on destination** adjacent to the source and destination selection, click the **Active** button to toggle between turning ON  and OFF  selections.

Two-Point Map

Use a **Two-Point Map** to control a **Boundary Similarity** component coupling mapping in 3D. Right-click the **Boundary Similarity** node to add a **Two-Point Map** subnode ().

SOURCE POINTS

To select a single **First point on source** and a single **Second point on source**, click the **Active** button to toggle between turning ON  and OFF  selections.

DESTINATION POINTS

To select a single **First point on destination** and a single **Second point on destination** adjacent to the destination selection, click the **Active** button to toggle between turning ON  and OFF  selections.

Edge Map

Use an **Edge Map** to control a **Boundary Similarity** component coupling mapping in 3D. Right-click the **Boundary Similarity** node to add a **Edge Map** subnode ().

EDGES

To select a single **Source edge** and a single **Destination edge**, click the **Active** button to toggle between turning ON  and OFF  selections. The destination edge is mapped to the source edge by the similarity mapping from destination to source.

ADVANCED

Select a relative **Direction** of the source and destination edges — **Automatic orientation** (the default), **Same orientation**, or **Opposite orientation**. This specifies the relative direction of the source and boundary edges and specifies which one of the two possible similarity mappings between the source and destination edge to use.

Identity Mapping

An **Identity Mapping** component coupling () maps between geometric entities that overlap, possibly when viewed in different frames. When it is evaluated at a specific set of coordinates in the destination frame, its argument is evaluated with the same coordinates in the source frame. The default **Operator name** is `idmap1`.

FRAMES

Select a **Source frame** to use on the source geometric entity and a **Destination frame** to use on the destination geometric entity. In most cases the default **Spatial** frame can be used since that will create a mapping between the points which coincide at each instant when the geometry is deforming. In other cases, the **Material**, **Geometry**, or **Mesh** frame can be more appropriate, but typically the same frame is used for both source and destination.

Go to [Common Settings for Component Couplings](#) for information about the **Operator Name**, **Source Selection**, and **Advanced** sections.

With the Acoustics Module, see *Ultrasonic Flow Meter with Piezoelectric Transducers: Coupling between FEM and DG*: Application Library path **Acoustics_Module/Ultrasound/flow_meter_piezoelectric_transducers**.

General Projection

Use a **General Projection** component coupling () to define integration along curves. A projection coupling operator evaluates an expression defined on a source by integration along lines or curves depending on the evaluation point in the destination. The General Projection operator is defined by mapping the source to an abstract intermediate space of dimension `srcedim`, and the destination to the subspace of dimension `srcedim-1` obtained by setting the last coordinate to 0 (`srcedim` is the dimension of the source selection). To every point in the

destination, there is a vertical line in the intermediate space, obtained by allowing the last coordinate to vary while the remaining coordinates are given by the destination map. The set of points in the source selection that are mapped onto this line by the source map is a line or curve, and the projection operator is evaluated by integrating along this line or curve. The default **Operator name** is genproj1.

See [Common Settings for Component Couplings](#) for information about the **Source Selection** section.

SOURCE MAP

Specify the general projection source map using expressions in the **x-expression**, **y-expression**, and **z-expression** fields.

The dimension of the intermediate space equals the dimension `srcedim` of the source. If the selection has lower dimension than the source geometry, specify only the first `srcedim` expressions.

Use expressions containing spatial coordinates in the source geometry when defining the map. The map must be approximately linear within each mesh element. Select a **Source frame** from the list.

DESTINATION MAP

Enter an **x-expression** and, depending on the dimensions, **y-expression** for each coordinate except the last in the intermediate space.

The destination map has one field less than the source map. When defining the map you can use expressions containing spatial coordinates in the destination geometry. The destination mapping can be highly nonlinear or noninvertible.

- If the selection has lower dimension than the source geometry, specify only the first `srcedim-1` expressions. A general projection operator can be evaluated at any point where its destination map is defined.
- If the source selection has dimension 1, no destination map needs to be specified, and consequently this section is not shown if the source geometry is 1D. In this case, it is probably better to use an integration coupling.

ADVANCED

Enter an **Integration order** of the numerical integration method (default: 4). See [integration order](#) in the *Glossary*.

Linear Projection

Use a **Linear Projection** component coupling () when the argument is to be integrated along a line, and the line depends linearly on the evaluation point.

The linear projection maps between a source and a destination of the nearest lower dimension. The source and destination can exist in geometries of different space dimensions. For example, you can couple domains in 2D to edges in 3D or couple 3D domains to 2D domains. You define the linear projection by specifying points in both the source and destination. The default **Operator name** is linproj1.

Go to [Common Settings for Component Couplings](#) for information about the **Operator name**, **Source Selection**, **Source Vertices**, and **Destination Vertices** sections.

SOURCE

Select a **Source frame** from the list to evaluate the coordinates of the source vertices in the selected frame.

Then specify the linear projection by giving a set of points in the source and in the destination. The order of the vertices is significant. COMSOL Multiphysics constructs a linear projection from the source to the destination using the subspaces spanned by the vertices. Denote the map rank by n , denote the source vertices by x_0, x_1, \dots, x_n , and denote the destination vertices x'_0, x'_1, \dots, x'_n . After padding the source and destination vertices' vectors with zeros as necessary, the software solves the following matrix equation for a *transformation matrix* T and a *translation vector* V :

$$\begin{aligned}x'_0 &= Tx_0 + V \\x'_1 - x'_0 &= T(x_1 - x_0) \\&\dots \\x'_n - x'_0 &= T(x_n - x_0)\end{aligned}$$

For the projection component coupling there must be one more vertex in the source than in the destination.

DESTINATION

Select an option from the **Destination geometry** list if there is more than one geometry in the model.

- A linear projection operator can only be evaluated on the destination geometry and the destination vertices must be chosen in the destination geometry.
- The destination vertex coordinates are evaluated in the selected **Destination frame**.

ADVANCED

Enter an **Integration order** of the numerical integration method (default: 4). See [integration order](#) in the *Glossary*.

Integration

An **Integration** component coupling ([*fdw*](#)) integrates an expression over the source (some selected geometric entities like domains, boundaries, or edges). You can also use it with a point as the source to make the value of an expression at that point available globally. The integral is evaluated by integrating the expression (integrand) in the argument over the source (or, in some cases, by summing the expression over the node points in the source).

Integration coupling operators have global destination, so they can be evaluated anywhere in the model. Because it is an operator, you can define one integration operator (`intop1`, for example) for a part of the geometry (a boundary, for example) and then use that several times in the model to compute integrals over that boundary for different integrands. For example, `intop1(T)` is the integral of the temperature T over the boundary, and `intop1(1)` is simply the length (2D) or area (3D) of the boundary. Also, using the `dest` operator it is possible to create convolution integrals. The default **Operator name** is `intop1`.

Go to [Common Settings for Component Couplings](#) for information about the **Operator name**, **Source Selection**, and **Advanced** sections.

- *Automotive Muffler*: Application Library path: **COMSOL_Multiphysics/Acoustics/automotive_muffler**
- *An Integro-Partial Differential Equation*: Application Library path **COMSOL_Multiphysics/Equation_Based/integro_partial**

Average

An **Average** component coupling () computes the average of an expression over the source (some selected geometric entities). It can be evaluated anywhere in the model. It is similar to the Integration operator; the difference being that the integral is divided by the volume, area, arc length, or number of points in the source, depending on the type of geometric entities in the source. The default **Operator name** is aveop1.

Go to [Common Settings for Component Couplings](#) for information about the **Operator name**, **Source Selection**, and **Advanced** sections.

Effective Diffusivity in Porous Materials: Application Library path **COMSOL_Multiphysics/Diffusion/effective_diffusivity**

Maximum and Minimum

The **Maximum** () and **Minimum** () coupling operators compute the maximum or minimum of an expression over selected geometric entities in the source and gives the maximum or minimum value of the expression in the argument over the source. The operator can be evaluated anywhere in the model. Two arguments can be given, and the returned value is then the value of the second argument evaluated in the max/min of the first argument. This is useful for evaluating, for example, the location of the maximum or minimum. In a 2D model where the temperature T is solved for, use the following syntax for the maximum operator maxop1 in a **Global Evaluation** node, for example, to get the x - and y -coordinate for the maximum of the temperature: `maxop1(T, x)` and `maxop1(T, y)`. The Maximum and Minimum operators support the **dest** operator, which forces evaluation in the destination points instead of the source points (see [dest](#)). The default **Operator name** is maxop1 or minop1.

When a **Max/Min Volume**, **Max/Min Surface**, or **Max/Min Line** plot is used, the maximum and minimum values, along with the coordinates for the corresponding locations, appear in a table (underneath the plot with the default COMSOL Desktop layout).

ADVANCED

Select a **Point type** — **Node points** (the default), **Integration points**, or **Lagrange points**. The point type controls the choice of evaluation points — the result is more accurate with more points, but more points also means a slower evaluation.

- If **Integration points** is selected, enter an **Integration order**. The default is 4. See [integration order](#) in the *Glossary*.
- Select **Lagrange points** to compute the maximum or minimum by evaluating the expression in the argument at a finite set of points in the source and taking the maximum or minimum of these values. If it is selected, enter a **Lagrange order**. The default is 2.

Go to [Common Settings for Component Couplings](#) for information about the **Operator name** and **Source Selection** sections.

Deformation of a Feeder Clamp: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/feeder_clamp**

Common Settings for Component Couplings

The following sections in the **Settings** windows for the component coupling nodes are similar or the same for some of the component coupling nodes and are described in this section.

OPERATOR NAME

Enter a name for the operator in the **Operator name** field or use the default name. This is the name that is used to access the operator in the model, so use a name that describes it well. For example, `genext1` is the default name for the first General Extrusion coupling operator, and you can use it to evaluate a temperature T in the destination using `genext1(T)`, for example.

SOURCE SELECTION

The source selection defines the source for the component coupling — the part of the geometry where the coupling operator evaluates the supplied expressions.

From the **Geometric entity level** list, select **Domain**, **Boundary**, **Edge** (3D only), or **Point**. Select **Manual** or **All domains**, **All boundaries**, **All edges**, or **All points** from the **Selection** list. If **Manual** is selected, select geometric entities in the **Graphics** window. Select **All domains**, for example, to add all applicable geometry to the **Selection** list.

SOURCE VERTICES AND DESTINATION VERTICES

The selection of **Source Vertices** and **Destination Vertices** define the linear mapping from the destination to the source.

Click the **Active** button to activate one of the vertex selections. You can toggle between turning ON and OFF selections.

Select a single source vertex for each of **Source vertex 1**, **Source vertex 2**, **Source vertex 3**, and **Source vertex 4**. Then select a single destination vertex for each of **Destination vertex 1**, **Destination vertex 2**, **Destination vertex 3**, and **Destination vertex 4** (vertex 4 is available for [Linear Extrusion](#) only).

- For [Linear Extrusion](#): The number of source vertices must be at least one and not more than $1+\min(\text{srcsdim}, \text{dstsdim})$, where `srcsdim` and `dstsdim` are the dimensions of the source and destination geometries, respectively. The number of destination vertices entered should be the same as the number of source vertices. If not all destination vertex selections are used, the empty selections must be last.
- For [Linear Projection](#), select `srcsdim+1` source vertices where `srcsdim` is the dimension of the source selection. Depending on the dimension of the source selection, it can be that some of the last source vertex selections should be left empty. The number of destination vertices should be *one less* than the number of source vertices. If not all destination vertex selections are used, the empty selections must be last. Select `srcsdim` destination vertices where `srcsdim` is the dimension of the source selection. Depending on the dimension of the source selection, it can be that some of the last destination vertex selections should be left empty.

An evaluation point in the destination geometry is first orthogonally projected onto the linear space spanned by the destination vertices (unless they span the entire space). The projected point is then mapped to the source geometry by a linear mapping taking each destination vertex to the corresponding source vertex. Let L be the line through this point, which is parallel to a line through the first and last source vertices. If the source selection lies in the linear space spanned by the source vertices, the Linear Projection operator is evaluated by integrating along L . In general the operator is evaluated by integrating along the line or curve in the source selection, which is mapped to L under orthogonal projection onto the linear space spanned by the source vertices.

SOURCE BOUNDARIES AND DESTINATION BOUNDARY

Select **Manual** or **All boundaries** from the **Selection** list to define the source selection. If **Manual** is selected, select boundaries in the **Graphics** window. Select **All boundaries** to add all boundaries to the **Selection** list.

There can only be one destination boundary. Click the **Active** button to enable or disable the **Destination Boundary** selection. Then choose the boundary in the **Graphics** window.

SOURCE FRAME AND SOURCE MAP

Select a **Source frame** to use in the source. In most cases the **Source** section default settings can be used. Optionally, select the **Use source map** check box and enter expressions in the **x-expression**, **y-expression**, and **z-expression** fields (in 3D) for the source map from the source to the intermediate mesh.

For the **General Extrusion** component coupling, the number of source map expressions is the same as the number of destination map expressions. With the default source map expressions, the intermediate mesh can be considered identical to the source.

The dimensionality idim of the intermediate space is determined by the number of nonempty source and destination map expressions, which must be the same, and must also satisfy $\text{scredim} \leq \text{idim} \leq \text{sresdim}$, where scredim is the dimension of the source selection, and sresdim is the dimension of the source geometry.

ADVANCED SETTINGS FOR COMPONENT COUPLINGS

For the **General Extrusion**, **Linear Extrusion**, **Boundary Similarity** and **Identity Mapping** component couplings, select an option from the **Mesh search method** list to specify what should happen if an evaluation point in the destination is mapped to a point outside the source:

- If **Use tolerance** is selected (the default) the result depends on the other field definitions in this section.
- If **Closest point** is selected, the closest point in the source selection is used.

Enter a scalar positive value in the **Extrapolation tolerance** field. If the mapped point is within a distance of the extrapolation tolerance times the mesh element size, the point is considered to be in the source. Otherwise, the mapping fails.

Select the **Use NaN when mapping fails** check box to evaluate the operator to NaN (Not-a-Number) if the mapping fails. Otherwise an error occurs.

For the **Integration** and **Average** couplings, select **Integration** or **Summation over nodes** from the **Method** list. In most cases use integration. Summation over nodes is useful, for example, for calculating reaction forces. If **Integration** is selected, enter a value in the **Integration order** field (see **integration order** in the *Glossary*). Also, when working with multiple frames, select a **Frame** from the list for the volume element to be used in the integration.

For axisymmetric geometries, the **Compute integral in revolved geometry** check box is selected by default to perform the integration in 3D (for a 2D axisymmetric model) or in 2D (for a 1D axisymmetric model).

Coordinate Systems

About Coordinate Systems

COMSOL Multiphysics uses a global Cartesian coordinate system by default to specify material properties, loads, and constraints in all physics interfaces and on all geometric entity levels (points, edges, boundaries, and domains). In boundary conditions and fluid domains, the global system is generally interpreted as having fixed axis directions in space; that is, it is a *spatial frame* system. When specifying properties of solid materials, the global system axes are instead fixed in the material. In other words, it is a *material frame* system in that context.

Not only the global coordinate system, but also coordinate systems defined as a rotation relative to the global system, are context-dependent in this way. Such systems are collectively referred to as *relative coordinate systems*, to distinguish them from *absolute coordinate systems*.

The spatial Cartesian coordinate system coordinates default to the following names in 2D and 3D (in 2D axisymmetric geometries, COMSOL Multiphysics uses cylindrical coordinates):

GEOMETRY	DEFAULT NAME OF SPATIAL COORDINATES
2D	x y
3D	x y z
Axial symmetry 2D	$r\phi$ z

In 3D, an image displays in the lower-left corner of the **Graphics** window  to indicate the orientation of the global coordinate system.

User-defined coordinate systems can be used on all geometric entity levels to simplify the modeling process. In the physics interfaces, you can use these coordinate systems to define orthotropic and anisotropic material properties that are not aligned with the global Cartesian coordinate system. To choose a coordinate system, select it from the **Coordinate system** list in the **Coordinate System Selection** section. The list contains the **Global coordinate system** (the default) and any other coordinate systems that you have added, for example see [Figure 5-3](#).

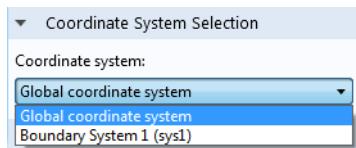

Figure 5-3: An example of options available in the Coordinate system list. The default is the Global coordinate system.

See [Table 5-17](#) for an overview of the available coordinate systems. Note in particular that some coordinate systems specify absolute directions in space, while others specify a rotation relative to the default global system, as indicated by the Type column in the table.

To add a Coordinate System to any Component:

- In the **Definitions** toolbar, select features from the **Coordinate Systems** menu, or
- Right-click the **Definitions** (≡) node and choose an option from the **Coordinate Systems** submenu. :

TABLE 5-17: COORDINATE SYSTEM DESCRIPTIONS

NAME AND LINK	ICON	TYPE	DESCRIPTION
Base Vector System		relative	ID, 2D, and 3D. Define this using a set of base vectors to form a coordinate system.
Boundary System		absolute	2D and 3D. A local base vector system on 2D boundaries (t, n) and on 3D boundaries (t_1, t_2, n). Use it to apply loads that apply in a normal or tangential direction on a boundary that is not aligned with the global Cartesian coordinate system. This coordinate system is always available. You can add Reverse Normal and Domain Normal subnodes to reverse the normal for some boundaries and switch the normal direction on the exterior of some domains, respectively.
Combined System			ID, 2D, and 3D. Use a combined system when you need to use different coordinate systems in different domains to represent some material property, for example. You can add applicable coordinate systems as subnodes, each with a geometric entity selection.
Cylindrical System		absolute	2D and 3D. Use a cylindrical system when rotational symmetry about the axis is required. Not available in geometries with 2D axial symmetry, where a cylindrical coordinate system is the default coordinate system.
Mapped System		absolute	ID, 2D, and 3D. The mapped system can deal with translated and rotated coordinate systems. Use this to create a system that defines a mapping from the frame coordinate system.
Rotated System		relative	2D and 3D. Use a rotated system to define rotation about the out-of-plane direction in 2D and Euler angles in 3D.
Scaling System		absolute	For physics that support infinite elements or perfectly matched layers only. Use this coordinate system, which is similar to a mapped coordinate system, to arbitrarily deform the domain.
Spherical System		absolute	3D only. Use a spherical system when a field or property using spherical coordinates is to be specified.
System from Geometry		absolute	3D only. Use a coordinate system from a work plane in a 2D geometry or a 3D geometry part.

- Grouping Nodes by Space Dimension and Type
- Spatial Coordinate Variables

Base Vector System

Define a **Base Vector System** () using a set of base vectors to form a coordinate system. The system does not necessarily need to be orthonormal, but when it is, declaring it orthonormal and linear enables simplifications that improve performance.

A vector \mathbf{F} is represented by its contravariant components $[F_1, F_2, F_3]^T$ in the base of the new base vector system defined by the base vectors $\mathbf{u}_1, \mathbf{u}_2$, and \mathbf{u}_3 on the form $\mathbf{F} = F_1\mathbf{u}_1 + F_2\mathbf{u}_2 + F_3\mathbf{u}_3$. Expressing the base vectors as components in another system (for example, the global spatial system [$\mathbf{e}_x, \mathbf{e}_y, \mathbf{e}_z$]) gives the transformation matrix between bases:

$$\begin{bmatrix} F_x \\ F_y \\ F_z \end{bmatrix} = [\mathbf{u}_1 \ \mathbf{u}_2 \ \mathbf{u}_3] \cdot \begin{bmatrix} F_1 \\ F_2 \\ F_3 \end{bmatrix}$$

$$\begin{bmatrix} F_1 \\ F_2 \\ F_3 \end{bmatrix} = [\mathbf{u}_1 \ \mathbf{u}_2 \ \mathbf{u}_3]^{-1} \cdot \begin{bmatrix} F_x \\ F_y \\ F_z \end{bmatrix} = \left\{ \begin{array}{l} |\mathbf{u}_i| = 1 \\ \mathbf{u}_i \cdot \mathbf{u}_j = \delta_{ij} \end{array} \right\} = [\mathbf{u}_1 \ \mathbf{u}_2 \ \mathbf{u}_3]^T \cdot \begin{bmatrix} F_x \\ F_y \\ F_z \end{bmatrix}$$

where the last equality holds when the base vector system is orthonormal.

Note that you specify the base vectors as components in the default global coordinate system, which is context-dependent. The base vector system is therefore a relative coordinate system whose interpretation depends on the interpretation of the global system in the current context.

The Curvilinear Coordinates interface can create special base vector systems in **Curvilinear System** nodes (). See [Curvilinear Coordinates](#).

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields are not available in this case.

SETTINGS

Coordinate names

In the **Coordinate names** table, the default names are entered — **x1**, **x2**, and **x3**. In planar 2D models, **x1** and **x2** are typically the in-plane coordinates, and **x3** is the out-of-plane coordinate. Note that these coordinate names are only used as indices for vector and tensor variable names, and cannot be evaluated as variables.

Base vectors

Define the **Base vectors** in terms of the global Cartesian coordinates (typically **x**, **y**, and **z**); one base vector on each row (two for 2D and three for 3D).

	For 1D models, select which basis vector is parallel to the 1D geometry. Select an option from the In-plane index list. The default is 1 .
	For 2D models, select which basis vector to compute as the cross product of the two in-plane vectors specified. Select an option from the Out-of-plane index list. The defaults are 3 for a plane 2D model and 2 for an axisymmetric 2D model. For example, to map the first vector, x1 , to the direction defined by y = x in 2D, enter 1 in the fields under x and y on the x1 row.

Simplifications

For some applications, only orthonormal coordinate systems can be used. Since the base vectors entered in a **Base Vector System** node are not necessarily orthonormal, these systems are by default not allowed in contexts requiring orthonormality. To make the coordinate system available in such contexts, select either the **Assume orthonormal** check box or the **Make orthonormal** check box. The former instructs automatic variable transforms to use the entered **Base vectors** directly, but treat them as orthonormal — if they are not, results will be incorrect. The **Make orthonormal** check box enables a polar decomposition of the base vector matrix into a rotation matrix and a stretch matrix. The rotation matrix — which is orthonormal — is kept, while the stretch matrix is discarded. This procedure

is computationally more expensive than assuming orthonormality but guarantees a truly orthonormal transformation matrix that will behave correctly in subsequent variable transforms.

RELATIVE TO SYSTEM FROM GEOMETRY

This section is available in 3D, if you have added any work plane to the geometry.

From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane in the geometry sequence. If you choose a work plane, the work plane's coordinates **xw**, **yw**, and **zw** are used for the definition of the base vector.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

- If you have the Nonlinear Structural Materials Module, see *Pressurized Orthotropic Container*: Application Library path **Nonlinear_Structural_Materials_Module/Plasticity/orthotropic_container**.
- If you have the Structural Mechanics Module, see *Piezoelectric Shear-Actuated Beam*: Application Library path **Structural_Mechanics_Module/Piezoelectric_Effects/shear_bender**.

Boundary System

A **Boundary System** () is a local base vector system on 2D boundaries (\mathbf{t} , \mathbf{n}) and on 3D boundaries (\mathbf{t}_1 , \mathbf{t}_2 , \mathbf{n}). Use it to apply loads and other boundary conditions in a normal or tangential direction on a boundary that is not aligned with the global Cartesian coordinate system.

For 3D and 2D models, a **Boundary System** node is automatically added under **Definitions**.

Common applications for this coordinate system include specifying pressure or normal displacement on a surface.

To specify the boundary coordinate system, you specify the direction of the normal and a direction that is projected onto the boundary, normalized, and used as the first tangent vector. The normal direction is in most cases the outward-pointing normal vector, but you can reverse the normal direction. The general definition of the normal is the direction of the normal vector \mathbf{n} , which can be plotted using the variables for its components (typically nx , ny , and nz). See [Normal Variables](#).

- In 2D, the local coordinate system is defined by $(\mathbf{t}_1, \mathbf{n}, \mathbf{t}_0)$, representing the tangential and normal direction of the boundary. This coordinate system is always right-oriented. The second tangent direction (\mathbf{t}_0) is the cross product between normal vector (\mathbf{n}) and the first tangent direction (\mathbf{t}_1). This method always gives a right-oriented orthonormal system, unless the tangent direction is parallel to the normal.
- In 3D, the local coordinate system is defined by $(\mathbf{t}_1, \mathbf{t}_2, \mathbf{n})$, representing two tangential directions (\mathbf{t}_1 and \mathbf{t}_2) and one normal direction (\mathbf{n}). This coordinate system is always right-oriented but not always orthogonal. The second tangent direction (\mathbf{t}_2) is the cross product between the specified normal vector (\mathbf{n}) and the first tangent vector (\mathbf{t}_1). This method always gives a right-oriented orthonormal system, unless the tangent direction is parallel to the normal.

You can also reverse the normal on some boundaries and switch the domain normal on the exterior of some domains by right-clicking the **Boundary System** node and selecting **Reverse Normal** and **Domain Normal**, respectively. See [Reverse Normal](#) and [Domain Normal](#).

SETTINGS

Frame

Select a **Frame: Deformed configuration** (the default), **Geometry configuration**, or **Reference configuration**. The deformed configuration follows the material whereas the reference configuration has fixed basis directions in the spatial frame. The geometry configuration is used to specify normal and tangential components of boundary conditions and refers to the undeformed geometry when using a Deformed Geometry interface.

Coordinate names

In the **Coordinate names** table, the default names are entered — t1, t2, and n (for 3D models) or t1, n, and to (for 2D models). Click the table cells to edit the names. To reverse the direction of the normal for the boundary system, select the **Reverse normal direction** check box.

Select an option from the **Create first tangential direction from** list: **Global Cartesian (spatial)** (the default), **Global Cartesian (material)**, **Global Cartesian (geometry)**, or any other applicable coordinate system that you have added. If **Global Cartesian (spatial)** is selected, select **x**, **y**, or **z** from the **Axis** list. If **Manual** is selected from the **Axis** list, default values are displayed for the local tangent variables `root.t1x`, `root.t1y`, and `root.t1z` (3D) or `root.t1x` and `root.t1y` (2D). Enter other values as needed to define a tangent direction by specifying directions for a local tangent plane in the **x**, **y**, and **z** fields.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

Many examples use this coordinate system. For one example, see *Electric Sensor*: Application Library path **COMSOL_Multiphysics/Electromagnetics/electric_sensor**.

Reverse Normal

Add a **Reverse Normal** node () as a subnode to a **Boundary System** node to reverse the normal on some boundaries.

In the **Boundary Selection** section, add the boundaries for which the boundary system's normal direction should be reversed.

Domain Normal

Add a **Domain Normal** node () as a subnode to a **Boundary System** node to switch the normal direction on the exterior of some domains.

In the **Domain Selection** section, add the domain for which the boundary system's normal direction should be switched.

NORMAL DIRECTION

From the **Normal direction** list, choose **Outward** (the default) or **Inward** to defined the normal direction on the exterior of the selected domains.

Combined System

A **Combined System** () can be used in 1D, 2D, and 3D when you want to refer to different coordinate systems in different domains. It can then be used, for example, as a single coordinate system selection in a physics setting, where some material property is defined using different coordinate systems in different domains. Right-click the Combined System node to add any of the following coordinate systems:

- Base Vector System
- Mapped System
- Rotated System (2D and 3D only)
- Cylindrical System (2D and 3D only)
- Spherical System (3D only)
- System from Geometry (3D only)

For each added coordinate system, use the geometric entity selection to define where in the geometry that coordinate system is used.

SETTINGS

Frame

Select with respect to which **Frame — Material** (the default), **Mesh**, **Geometry**, or **Spatial** — the coordinate system is defined by the above transformations. Note that the actual coordinate names — typically **(x, y, z)** or **(X, Y, Z)** in 3D — are displayed for each frame, indicating which frames differ from each other in the current model.

A coordinate system with **Frame** set to **Spatial** is orthonormal only in the spatial frame. Similarly, a **Material** system is orthonormal only in the material frame. Some physics require that coordinate systems used are orthonormal in a particular frame. For example, choose the **Material** frame if you want to use the coordinate system in a structural mechanics model.

Coordinate names

In the **Coordinate names** table, the default **Coordinate names** are entered — **x1**, **x2**, and **x3**.

Cylindrical System

A **Cylindrical System** () can be used in 2D and 3D where rotational symmetry about the axis is required. The cylindrical coordinate system is not applicable in geometries with 2D axial symmetry. The local coordinate system is defined by (r, φ, a) , where r represents the radial distance from the longitudinal axis, φ is the azimuthal angle (in the interval from $-\pi$ to π), and a is the distance from the origin along the longitudinal axis. In 2D models, only the origin can be specified, whereas in 3D models, the longitudinal axis direction, \mathbf{a} , and the radial base vector, \mathbf{e}_r ($\varphi = 0$), can be specified as well. These direction vectors are automatically normalized.

The definitions of the cylindrical coordinates in terms of the global Cartesian coordinates $\mathbf{r} = \mathbf{r}(x, y, z)$ are

$$\begin{bmatrix} r \\ \varphi \\ a \end{bmatrix} = \begin{bmatrix} \left[\mathbf{r} - (\mathbf{r}_0 + \mathbf{a}(\mathbf{a} \cdot (\mathbf{r} - \mathbf{r}_0))) \right] \\ \text{atan} \frac{(\mathbf{a} \times \mathbf{e}_r) \cdot (\mathbf{r} - \mathbf{r}_0)}{\mathbf{e}_r \cdot (\mathbf{r} - \mathbf{r}_0)} \\ \mathbf{a} \cdot (\mathbf{r} - \mathbf{r}_0) \end{bmatrix}$$

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields and the **Frame** list are not available in this case.

SETTINGS

Frame

Select with respect to which **Frame** — **Spatial** (the default), **Mesh**, **Material**, or **Geometry** — the coordinate system is cylindrical as defined by the above transformations. Note that the actual coordinate names — typically **(x, y, z)** or **(X, Y, Z)** in 3D — are displayed for each frame, indicating which frames differ from each other in the current model.

A coordinate system with **Frame** set to **Spatial** is orthonormal only in the spatial frame. Similarly, a **Material** system is orthonormal only in the material frame. Some physics require that coordinate systems used are orthonormal in a particular frame. For example, choose the **Material** frame if you want to use the coordinate system in a structural mechanics model.

Coordinate names

In the **Coordinate names** table, the default **Coordinate names** are entered — **r**, **phi**, and **a**. In planar 2D models, **r** and **phi** are in-plane polar coordinates, and **a** is the out-of-plane coordinate.

Origin

Specify the location of the **Origin** of the cylindrical coordinate system in the global Cartesian system. The default is an origin coinciding with the one from the global system.

Longitudinal axis

For 3D models, enter the **Longitudinal axis direction**. The default is the **z** direction in the global system.

Direction of axis

For 3D models, specify the **Direction of axis** **φ=0**, where **φ** is the azimuthal angle. The default direction is the **x** direction in the global system.

RELATIVE TO SYSTEM FROM GEOMETRY

This section is available in 3D, if you have added any work plane to the geometry.

From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane in the geometry sequence. If you choose a work plane, the work plane's coordinates **xw**, **yw**, and **zw** are used for the definition of the origin and axis.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

Mapped System

Use a **Mapped System** () to create a coordinate system that defines a mapping from the frame coordinate system.

A mapped system can deal with translated and rotated coordinate systems:

$$\begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \begin{bmatrix} u_1(x, y, z) \\ u_2(x, y, z) \\ u_3(x, y, z) \end{bmatrix}$$

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields and the **Frame** list are not available in this case.

SETTINGS

The **Frame** list is the same as for the [Cylindrical System](#).

Coordinate names

In the **Coordinate names** table, the default names are entered — x_1 , x_2 , and x_3 . In planar 2D models, x_1 and x_2 are typically the in-plane coordinates, and x_3 is the out-of-plane coordinate.

Coordinate mapping

Under **Coordinate mapping**, the **Coordinate** column displays the **Coordinate names** with the **Expression** column displaying the associated mapped coordinate.

Simplifications

If required, select the **Assume orthonormal** check box. The program then uses the assumption that the settings define an orthonormal coordinate system.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

Rotated System

Use a **Rotated System** () to define rotation about the out-of-plane axis in 2D and Euler angles in 3D.

In the **Settings** window for **Rotated System** define the rotation of the system axes relative to the global Cartesian coordinate system. In 3D models, you orient the rotated system axes (denoted **X**, **Y** and **Z** in [Figure 5-4](#)) using three consecutive Euler angles α , β , and γ , using a **Z-X-Z** convention.

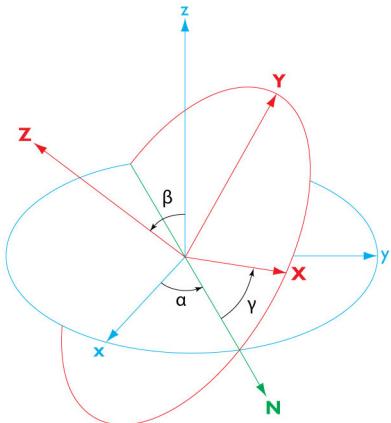

Figure 5-4: 3D Euler angles in a rotated coordinate system.

The transformation matrix defined by the Euler angles transforms components of a fixed vector \mathbf{v} from the rotated coordinate system, $[v_X, v_Y, v_Z]$, to components in the global system, $[v_x, v_y, v_z]$, as follows:

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} \cos\alpha\cos\gamma - \sin\alpha\cos\beta\sin\gamma & -\cos\alpha\sin\gamma - \sin\alpha\cos\beta\cos\gamma & \sin\beta\sin\alpha \\ \sin\alpha\cos\gamma + \cos\alpha\cos\beta\sin\gamma & -\sin\alpha\sin\gamma + \cos\alpha\cos\beta\cos\gamma & -\sin\beta\cos\alpha \\ \sin\beta\sin\gamma & \sin\beta\cos\gamma & \cos\beta \end{bmatrix} \cdot \begin{bmatrix} v_X \\ v_Y \\ v_Z \end{bmatrix}$$

In 2D models, you describe the rotated coordinate system by the rotation angle about a selected out-of-plane axis. This is a two-step process. You first select which axis of the rotated system should point into or out of the screen. This defines a new reference orientation for the axes remaining in-plane. Then specify a rotation angle relative to the new reference.

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields are not available in this case.

SETTINGS

Coordinate names

In the **Coordinate names** table, the default names are entered — **x1**, **x2**, and **x3**. In planar 2D models, **x1** and **x2** are typically the in-plane coordinates, and **x3** is the out-of-plane coordinate.

Out-of-plane axis (2D)

For 2D models, select an out-of-plane axis from the **Out-of-plane axis** list (first, second, or third coordinate direction into or out-of screen). The **Base vectors** table updates to reflect the new reference orientation of the in-plane axes. Enter a **Rotation about out-of-plane axis** (in radians) to rotate the system relative to the new base vectors, in a counterclockwise direction about the chosen out-of-plane axis. The default rotation is 0.

Euler angles (3D)

For 3D models, enter the **Euler angles (Z-X-Z)** (in radians) in the α , β , and γ fields (see the graphics in the **Settings** window for definitions of these angles). The default values are 0 for all angles.

RELATIVE TO SYSTEM FROM GEOMETRY

This section is available in 3D, if you have added any work plane to the geometry.

From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane in the geometry sequence. If you choose a work plane, the work plane's coordinates **xw**, **yw**, and **zw** are used for the definition of the rotated system.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

With the MEMS Module, see *Gecko Foot*: Application Library path **MEMS_Module/Actuators/gecko_foot**.

Spherical System

Use a **Spherical System** () to define a spherical coordinate system in 3D by its origin, zenith axis, and azimuth axis.

The coordinates of a local spherical coordinate system are (r, θ, ϕ) , where r represents the radial distance from the origin, θ is the inclination (in the interval from 0 to π), and ϕ is the azimuthal angle (in the interval from $-\pi$ to π). Specify — in terms of the global Cartesian coordinates x , y , and z — the position of the origin, the axis $\theta = 0$ (the zenith axis, **Z**), and the axis $\theta = \pi/2$, $\phi = 0$ (the azimuth axis, **A**). The direction vectors are automatically normalized.

This is a mapped normalized coordinate system using the following transform in global coordinates

$$r = |\mathbf{r} - \mathbf{r}_o|$$

$$\theta = \arccos\left(\frac{\mathbf{Z} \cdot (\mathbf{r} - \mathbf{r}_o)}{|\mathbf{r} - \mathbf{r}_o|}\right)$$

$$\phi = \text{atan2}(\mathbf{r}_{\perp} \cdot (\mathbf{Z} \times \mathbf{A}), \mathbf{r}_{\perp} \cdot \mathbf{A})$$

where \mathbf{r}_o is the position of the origin, \mathbf{Z} is a unit vector along the axis $\theta = 0$, and the component of $\mathbf{r} - \mathbf{r}_o$ in the plane $\theta = \pi/2$ is

$$\mathbf{r}_{\perp} = (\mathbf{r} - \mathbf{r}_o - \mathbf{Z}(\mathbf{Z} \cdot (\mathbf{r} - \mathbf{r}_o)))$$

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields and the **Frame** list are not available in this case.

SETTINGS

The **Frame** list is the same as for the [Cylindrical System](#).

In the **Coordinate names** table, the default **Coordinate names** are entered — r , θ , and ϕ .

Enter the location of the **Origin** in the global Cartesian coordinate system. The default is an origin coinciding with that of the global system.

Enter the **Direction of axis $\theta=0$** (the *zenith axis*). The default axis direction is the z direction in the global Cartesian system.

Define the **Direction of axis $\theta=\pi/2$, $\phi=0$** (the *azimuth axis*). The default direction is the x direction in the global Cartesian system.

RELATIVE TO SYSTEM FROM GEOMETRY

This section is available in 3D, if you have added any work plane to the geometry.

From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane in the geometry sequence. If you choose a work plane, the work plane's coordinates **xw**, **yw**, and **zw** are used for the definition of the origin and axis.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

System from Geometry

Use a **System from Geometry** (coordinate system to create a coordinate system that is aligned with a work plane in a 3D geometry sequence or geometry part. Such a coordinate system makes it possible to specify geometric primitives and to transform geometry features using a coordinate system that is aligned with the surface of some other geometry primitive, for example. It can also make it easier to specify the directions of anisotropic materials.

If this coordinate system is added as a subnode to a **Combined System** node, define where it will be active using a selection in the **Geometric Entity Selection** section. Also, the **Name** and **Coordinate names** fields and the **Frame** list are not available in this case.

SETTINGS

The **Frame** list is the same as for the [Cylindrical System](#) or [Mapped System](#).

In the **Coordinate names** table, the **Coordinate names** are entered — $x1$, $x2$, and $x3$ by default.

SYSTEM FROM GEOMETRY

In this section, you select the work plane that defines the coordinate system.

If there are work planes both in the geometry and in some geometry parts, you can choose the source of the work plane from the **Take work plane from** list: **This geometry** (the default), to use a work plane from the geometry sequence in the component, or a part instance with a work plane that is used in the geometry.

From the **Work plane** list, select any of the work planes in the geometry sequence or part instance. The selected work plane then defines the coordinate system.

Scaling System

Use a **Scaling System** () to create a system that maps the geometry, as represented by the independent coordinates of an underlying frame, onto a virtual geometry represented by virtual scaling system coordinates. Physics interfaces that support infinite elements or perfectly matched layers accept the scaling system coordinates as being the physical domain, in which the underlying frame coordinates are seen as a parameterization. Therefore, using a scaling coordinate system you can arbitrarily deform the domain, essentially in the same way as when using Deformed Geometry with a Prescribed Deformation node.

The Scaling System is only available for physics that support infinite elements or perfectly matched layers. See [Infinite Element Domain](#).

The scaling coordinate system is defined as a map from real frame coordinates to virtual scaling system coordinates:

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x_1(x, y, z) \\ x_2(x, y, z) \\ x_3(x, y, z) \end{bmatrix}$$

The selected frame coordinates (the setting is invisible if there is only one frame) are seen as a parameterization of the “true geometry” in which the physics is solved. What you specify in the **Coordinate mapping** table is therefore a “true position” for each point in the mesh, expressed in the frame coordinates. When applied to a domain with a compatible material model in a physics interface, the equations in that domain are first reformulated in terms of the virtual x_1 , x_2 , and x_3 coordinates but then automatically mapped back to the frame coordinates. This leads to explicit transformation expressions appearing in the equations.

SETTINGS

Under **Coordinate mapping**, the **Coordinate** column displays the virtual coordinate names with the **Expression** column displaying the map from underlying frame coordinates to virtual coordinates. The default expressions are the spatial coordinates x , y , and z , which means no scaling.

Go to [Name](#) for information about the **Settings** window **Label** and **Name**. Also see [Settings and Properties Windows for Feature Nodes](#).

Identity and Contact Pairs

Pairs are available for assemblies (that is, geometries created by not forming a union of all geometry objects as the final step), where there is a need to connect boundaries between parts. By default, pairs are created automatically when forming an assembly. There are two types of pairs — identity pairs and contact pairs.

About Identity and Contact Pairs

IDENTITY PAIRS

An *identity pair* (**Identity Boundary Pair** ) is a pair that, by default, makes the fields across two connected boundaries (one from each connecting object in an assembly) continuous. This is equivalent to the continuity that is obtained by default on interior boundaries in a geometry created by forming a union. Some physics provide special boundary conditions for identity pairs to model “slit conditions” such as resistive layers. You can specify boundary conditions for these pairs from the **Pairs** submenu at the bottom of the boundary condition part of the context menu for the physics feature node. The nodes in the **Model Builder** that represent pair boundary conditions use an icon with a pair symbol in the lower-left corner: . There are also similar **Identity Edge Pair**  and **Identity Point Pair**  pair nodes.

CONTACT PAIRS

A *contact pair*  is a pair that defines boundaries where the parts can come into contact but cannot penetrate each other under deformation for modeling of structural contact and multiphysics contact.

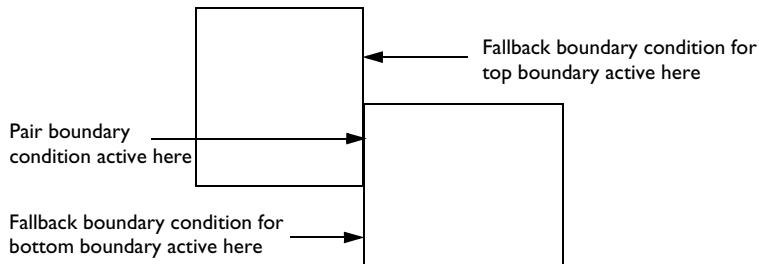

Contact pair modeling requires the Structural Mechanics Module or MEMS Module. Details about this pair type can be found in the respective user guide.

FALLBACK BOUNDARY CONDITIONS ON NONOVERLAPPING PARTS

For pairs where parts of the boundaries do not overlap you need to specify boundary conditions for the non-overlapping parts, which typically represent exterior boundaries outside of the overlapping area. These boundary conditions (*fallback* boundary conditions) appear as subnodes to the pair’s boundary condition node in the **Model Builder**. By default, the default boundary condition for exterior boundaries is added to the nonoverlapping parts. If you want to use another boundary condition for any of the nonoverlapping parts, right-click the pair’s boundary condition node (**Continuity**, for example) and select any of the standard boundary conditions from the **Fallback Features** submenu. In the **Settings** window, the selection includes all applicable boundaries by default, but a separate boundary condition can be added for only a subset of the pair boundaries. In the following illustration, which shows a simple example with two partially overlapping rectangles, there is one identity pair that consists of two boundaries, each with a nonoverlapping part. You can right-click the pair’s boundary condition node and, from the **Fallback**

Features submenu, add one fallback boundary condition for the top boundary and another fallback boundary condition for the bottom boundary if desired.

The options for the available fallback conditions are based on the physics interface and the license type (see [Figure 5-5](#)).

With only a few exceptions for the Solid Mechanics interface or other physics interfaces using Solid Mechanics functionality, all subnodes to pairs are fallback nodes.

When additional fallback feature nodes are added, the node has an indicator in the lower-left corner () identifying it as a fallback feature node.

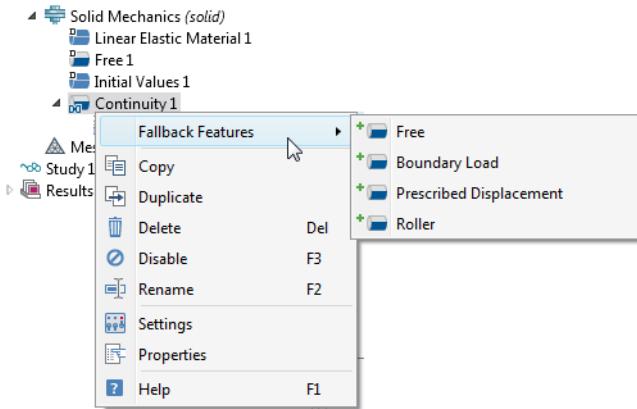

Figure 5-5: An example of the Fallback Features submenu for a Continuity pair added to the Solid Mechanics interface.

To add Pairs to any Component:

- In the **Definitions** toolbar, select features from the **Pairs** menu, or
- Right-click the **Definitions** (≡) node and choose an option from the **Pairs** submenu.

Go to [Pair Name](#) for information about the **Settings** window **Pair name**. Also see [Settings and Properties Windows for Feature Nodes](#).

Identity Pairs

Use an identity pair node (≡ for an identity boundary pair) to specify two selections of boundaries that overlap but belong to different parts of an assembly. Then assign a boundary condition to connect the physics nodes in the two parts in a physics interface. Identity pairs connect overlapping boundaries in different connecting parts of an assembly.

The **Identity Boundary Pair** () is the most commonly used node. For 3D models, the **Identity Edge Pair** is available (), which can be useful for connecting two edges in a shell model, for example. You can also choose the **Identity Point Pair** ().

Go to [Pair Name](#) for information about the **Settings** window **Pair name**. Also see [Settings and Properties Windows for Feature Nodes](#).

GENERAL

Enter a **Pair name**. It is used as a suffix in names of operators and variables defined by the pair. The default **Pair type** is **Identity pair**, or select **Contact pair**. Identity and Contact pairs are both available for boundary pairs, and Identity pairs are also available on edge and point levels (where there is no **Pair type** list).

Manual control of selections

If the pair was created automatically when forming an assembly, the **Manual control of selections** check box is visible. Click to clear this check box to be able to make manual changes to the **Source Boundaries** and **Destination Boundaries** selections. Pairs in manual mode do not have their selections updated when the geometry sequence is rebuilt.

The operator mapping an expression E on the source side to the destination side is denoted $\text{src2dst}_{pn}(E)$, where $_{pn}$ is the pair name.

For an **Identity pair**, the variable src2dst_{pn} (defined on the destination) is 1 where there is a corresponding source point, and 0 otherwise. The corresponding operator and variable for use on the source side are denoted dst2src_{pn} .

Similarly, for a **Contact pair** there is an operator src2dst_{pn_mph} that is suited for use in multiphysics coupling. The variable $\text{geomgap}_{dst}_{pn}$ is the geometric gap between the source and the destination, seen from the destination side (following the normal of the destination boundary). The corresponding operators and variables for use on the source side are denoted dst2src_{pn} , dst2src_{pn_mph} , $\text{geomgap}_{src}_{pn}$.

SOURCE BOUNDARIES AND DESTINATION BOUNDARIES

The destination boundaries should overlap the source boundaries. The condition that connects the physics nodes on the destination and source boundaries is specified in the physics interface. For example, it can be a constraint that constrains a dependent variable (temperature, for example) on the destination side to be equal to a dependent variable on the source side.

Click the **Active** button to toggle between turning ON  and OFF  selections.

Then define the source or destination boundaries. Select **Manual** or **All boundaries** for the boundaries on the source or destination side. If **Manual** is selected, click in the **Graphics** window to add boundaries to the **Selection** section. If required, click the **Swap Source and Destination** button ().

Select **Manual** or **All boundaries** for the boundaries on the source side or the destination side. If **Manual** is selected, click in the **Graphics** window to add boundaries to the **Selection** section. If required, click the **Swap Source and Destination** button () to swap the source boundaries and the destination boundaries.

For **Identity Edge Pairs** and **Identity Point Pairs**, edges and points, respectively, replace boundaries in the selections of the pair's source and destination.

FRAME

If there are several frames in the model, the **Frame** section is visible. Select the **Source frame** and the **Destination frame**. Source and destination points are connected if their coordinates in their respective frames are equal.

With the MEMS Module, see *Gecko Foot*: Application Library path **MEMS_Module/Actuators/gecko_foot**

Contact Pair

Use a **Contact Pair** node () to specify two selections of boundaries that cannot penetrate each other under deformation. The contact pairs define boundaries for parts that can come into contact (boundaries that cannot penetrate each other under deformation). For more information about contact modeling and guidelines for selecting source and destination boundaries for contact pairs, see the Structural Mechanics Module or MEMS Module documentation.

Go to [Pair Name](#) for information about the **Settings** window **Pair name**. Also see [Settings and Properties Windows for Feature Nodes](#).

GENERAL

This section is described for the [Identity Pairs](#) except that the default **Pair type** is **Contact pair**.

SOURCE BOUNDARIES AND DESTINATION BOUNDARIES

The contact algorithm constrains the destination boundaries so that they do not penetrate the source boundaries.

Click the **Active** button to toggle between turning ON and OFF selections.

Then define the source or destination boundaries. Select **Manual** or **All boundaries** for the boundaries on the source or destination side. If **Manual** is selected, click in the **Graphics** window to add boundaries to the **Selection** section. If required, click the **Swap Source and Destination** button () to swap the source boundaries and the destination boundaries.

ADVANCED

The **Search method** defaults to **Fast** — the algorithm only keeps track of source and destination points that have a distance less than a certain *search distance*. Select **Direct** for a slower but more robust search.

The **Mapping method** list is by default set to **Deformed configuration**. This setting means that whenever the source or destination has moved, a new search for possible contact points is made. If you know that the movements of the source and destination are small, selecting **Initial configuration** can be more efficient. In this case, a pairing between source and destination points is computed based on the initial configuration and always stays the same. This approach works well if the distance between source and destination is initially smaller than the search distance, and movements in the tangential direction are small.

Select the **Manual control of search distance** check box to tune the search distance (SI unit: m). By default, the search distance is taken as 0.01 times the diagonal of the geometry's bounding box. If the **Manual control of search distance** check box is selected, enter a different value in the **Distance** field.

You can use the **Extrapolation tolerance** setting (a fraction of the element length; default 10^{-4}) to effectively extend the source and destination boundaries slightly outside the selections. The size of this extension is equal to the extrapolation tolerance multiplied with the mesh element size.

	For a contact pair, the fallback boundary condition is applied to all parts of the boundaries currently not in contact.
	<ul style="list-style-type: none">With the MEMS Module, see <i>Piezoelectric Valve</i>: Application Library path MEMS_Module/Piezoelectric_Devices/piezoelectric_valve.With the Nonlinear Structural Materials Module, see <i>Snap Hook</i>: Application Library path Nonlinear_Structural_Materials_Module/Plasticity/snap_hook.With the Structural Mechanics Module, see <i>Cylinder Roller Contact</i>: Application Library path Structural_Mechanics_Module/Verification_Examples/cylinder_roller_contact.

Probes

About Probes

Probes () monitor the development of a scalar-valued quantity (real or complex-valued number) from a time-dependent, frequency-domain, or parametric simulation by two different results presentations: tabulated data and 1D graph plots. You can probe while solving, as a monitor and diagnostic tool, and probe after the computation is finished for results analysis. On top of this functionality, a probe variable in the model component's namespace and with a global evaluation scope is also defined. The probe variable's name appears in the **Probe variable** field. You can use this variable as any other variable in, for example, equations, boundary conditions, or a stop condition.

Plot while solving is a technique used to briefly interrupt the simulation and launch some predefined plot commands and then continue with the simulation. Both normal plots and graphs can be plotted for probes during the simulation.

There are these types of probes (see [Table 5-18](#) for the icon by space dimension):

- *Domain probes, boundary probes, and edge probes* make it possible to probe the average, minimum, maximum, or integral of a field quantity over a domain, on a boundary, or along an edge.
- *Domain point probes* and *boundary point probes* provide the value of some field quantity at a point in the domain or on a boundary. Any point within the domain or on the boundary can be defined.
- Use *Global variable probes* () for probing the value of any global variable.

The probes automatically create a **Probe Table** node for displaying numerical results in the **Table** window and an associated plot group with a **Probe Table Plot** node that plots the probe data as a line graph in a separate **Probe Plot** window. For further processing, the probes also add data sets such as **Domain Point Probe** data sets () which give access to the probe data. For further control, specify the table and plot window each probe uses.

To add a Probe to any Component:

- In the **Definitions** toolbar, select features from the **Probes** menu, or
- Right-click the **Definitions** () node and choose an option from the **Probes** submenu.

When the simulation has finished, click the **Update Results** button () in the probe **Settings** window (or in the **Definitions** toolbar) to change the settings for a probe and update the results information. Then right-click the **Definitions** node (or the **Probes** node if the **Definitions** nodes are grouped by type) and select  **Update Probes**.

TABLE 5-18: PROBE TYPES AND ICONS BY SPACE DIMENSION

PROBE TYPE	3D	2D	ID
Domain			
Boundary			
Edge		—	—
Domain Point			—
Boundary Point		—	—
Global Variable			

Common Settings for Probes

VARIABLE NAME

For all **Probes** you must specify a **Variable name** that is unique within the model component where the feature is added. You can use this Variable name in expressions, and it is also the node's **Tag**. A unique default Variable name is always generated when the node is created.

SOURCE SELECTION

The source selection defines the source for the probes — the part of the geometry over which the program computes the probes.

From the **Geometric entity level** list, select **Manual** or based on the probe type, **All domains**, **All boundaries**, **All edges**, or **All points** from the **Selection** list. If **Manual** is selected, select geometric entities in the **Graphics** window.

EXPRESSION

In the **Expression** section you can:

- Enter a text string with your own expression.
- Click the **Replace Expression** button to select a predefined quantity and replace the contents of the **Expression** field with the corresponding variable.
- Click the **Insert Expression** button to insert the corresponding variable at the current position in the **Expression** field.
- Select a **Table and plot unit** from the list. You can select from a predefined number of applicable units for the quantity that the variable represents, but you can also click in the unit's text field and type any compatible unit for that quantity to use a unit that is not in the list (for example, **mi/h** for miles per hour as a unit for a velocity quantity).
- Select the **Description** check box to enter a description (or edit the default).

- [About Parameters, Variables, Variable Utilities, and Expressions](#)
- [Entering Ranges and Vector-Valued Expressions](#)
- [Expressions and Predefined Quantities](#)

TABLE AND WINDOW SETTINGS

By default, COMSOL Multiphysics uses a probe table (typically **Probe Table 1**) under **Tables** and a probe table plot (typically **Probe Table Plot 1**) in a **Probe ID Plot Group** node, which appears in a separate plot window for probe plots (typically **Probe Plot 1**). To organize and group multiple probes, control the table and plot window to use for the probe results:

From the **Output table** list, select **Default**, **New table**, or any existing probe table. If an existing probe table is selected, click the **Go to Source** button () to move to the selected **Probe Table** node under **Tables**.

From the **Plot window** list, select **Default**, **New window**, or any existing plot window. Click the **Add Plot Window** button () to create a new plot window and make it the default for this list.

By default, for both the **Output table** and **Plot window**, COMSOL Multiphysics uses a probe table or probe plot that is created automatically. If **Default** is selected, COMSOL Multiphysics updates the list to show the name of the default probe table or probe plot window after the solution process.

Domain Probe, Boundary Probe, and Edge Probe

Use a **Domain Probe** (), **Boundary Probe** (), or **Edge Probe** () to monitor the development of a scalar-valued quantity (real or complex-valued number) from a dynamic simulation (time-dependent, frequency-domain, or parametric solution).

Go to [Common Settings for Probes](#) for information about the **Variable name**, **Source Selection**, **Expression**, and **Table and Window Settings** sections.

PROBE SETTINGS

Select an option from the **Type** list: **Average** (the default), **Maximum**, **Minimum**, or **Integral** depending on what type of value takes over the domain, boundary, or edge that you want the probe to compute and output. If needed, enter or edit a name for the **Probe variable**. The defaults are `dom1` for a Domain Probe, `bnd1` for a Boundary Probe, and `edge1` for an Edge Probe.

INTEGRATION SETTINGS

If you have selected **Average** or **Integral** from the **Type** list, the **Integration Settings** section contains the following settings:

- From the **Method** list, select **Integration** (the default) or **Summation**. Only reaction forces use the summation method.
- If desired, for the **Integration** method only, enter an integer value in the **Integration order** field (default: 4). See [integration order](#) in the *Glossary*.

When working with multiple frames for any type of probe, you can also select a **Frame — Spatial, Material, Geometry**, or **Mesh** — followed by the coordinate names: typically **(x, y, z)** or **(X, Y, Z)** depending on the physics in 3D, for the volume element to be used in the integration.

If the component's geometry is a 1D or 2D axisymmetric geometry, and the probe **Type** setting is set to **Average** or **Integral**, the **Compute surface integral** (for Domain Probe nodes in 1D axial symmetry and Boundary Probe nodes in 2D axial symmetry) and **Compute volume integral** (Domain Probe nodes in 2D axial symmetry) check boxes are selected by default to compute an average or integral that takes the axial symmetry into account. COMSOL Multiphysics multiplies the expression (integrand) with $2\pi r$ or πr^2 prior to integration to compute the corresponding surface or volume integral.

- With the Batteries & Fuel Cells Module: For a boundary probe example, see *Edge Effects in a Spirally Wound Lithium-Ion Battery*: Application Library path **Batteries_and_Fuel_Cells_Module/Batteries,_Lithium-Ion/li_battery_spiral_2d**. For a domain probe example, see *Mass Transport Analysis of a High Temperature PEM Fuel Cell*: Application Library path **Batteries_and_Fuel_Cells_Module/Fuel_Cells/ht_pem**.
- With the Nonlinear Structural Materials Module and for a boundary probe example, see *Snap Hook*: Application Library path **Nonlinear_Structural_Materials_Module/Plasticity/snap_hook**.

Domain Point Probe

Use a **Domain Point Probe** () to monitor the development of a real or complex-valued number from a dynamic simulation (a time-dependent, frequency-domain, or parametric study). By default a **Point Probe Expression** subnode is added, or right-click **Domain Point Probe** to add additional nodes.

POINT SELECTION

When working with multiple frames, select a **Frame — Spatial, Material, Geometry, or Mesh** — followed by the coordinate names, typically **(x, y, z)** or **(X, Y, Z)** in 3D depending on the physics.

For 3D models, select a **Line entry method: Point and surface normal** (the default), **Point and direction**, **Two points**, or **None**.

For all models, enter **Coordinates**: enter **x** and **y** coordinates (2D) or **x, y**, and **z** coordinates (3D). Also select the **Snap to closest boundary** check box to snap the point to the boundary of the geometry closest to that point when the probe is evaluated.

For **Point and surface normal**, **Point and direction**, or **Two points**, enter a **Depth along line** or use the slider to select a value between 0 and 1 to determine the probe location along the line anywhere from the starting point (0) to the ending point (1).

- For **Point and surface normal** click at a position on the surface of the geometry. The direction becomes the inward surface normal as defined by the geometry, which for an exterior boundary means that the probe location can be anywhere from the start position to the end of the geometry in the normal direction.
- For **Point and direction**, the direction becomes that of a ray directed away from the point in the current camera view (that is, the direction depends on the view).

For **Two points**, from the **Point being modified** list, also select **First point** and click on the geometry to define the first point (starting point). Then select **Second point** and click to define the second point (ending point) for the line.

Process Control Using a PID Controller: Application Library path **COMSOL_Multiphysics/Multiphysics/pid_control**

Boundary Point Probe

Use a **Boundary Point Probe** () to monitor the development of a scalar-valued quantity (real or complex-valued number) from a dynamic simulation (time-dependent, frequency, parametric). By default a **Point Probe Expression** subnode is added, or right-click **Boundary Point Probe** to add additional subnodes.

BOUNDARY SELECTION

Select a single boundary to add to the **Selection**.

POINT SELECTION

When working with multiple frames, select a **Frame — Spatial, Material, Geometry, or Mesh** — followed by the coordinate names: typically **(x, y, z)** or **(X, Y, Z)** depending on the physics in 3D.

Enter the **Coordinates**. A red dot indicates the position of the point on the selected surface in the **Graphics** window. Click the surface to move the point, or enter **x, y**, and **z** coordinates. If the point is not on the boundary, the probe location becomes the closest point on the boundary, with coordinates indicated by **On surface** under the fields.

Point Probe Expression

A **Point Probe Expression** () is automatically added as a subnode to a **Domain Point Probe** and a **Boundary Point Probe**. Right-click the main node to add additional **Point Probe Expression** subnodes. Under **Probe Settings**, edit or enter a name for the **Probe variable**. The default name is ppb1.

Go to [Common Settings for Probes](#) for information about the **Variable name**, **Expression**, and **Table and Window Settings** sections.

Global Variable Probe

Use a **Global Variable Probe** () to monitor the development of a scalar-valued quantity (real or complex-valued number) from a dynamic simulation (time-dependent, frequency, parametric). Under **Probe Settings**, edit or enter a name for the **Probe variable**. The default name is var1.

Go to [Common Settings for Probes](#) for information about the **Variable name**, **Expression**, and **Table and Window Settings** sections.

With the Corrosion Module, see *Estimation of Corrosion Kinetics Parameters*: Application Library path **Corrosion_Module/Galvanic_Corrosion/corrosion_parameter_estimation**.

With the RF Module, see *Microwave Filter on PCB*: Application Library path **RF_Module/Filters/pcb_microwave_filter_with_stress**.

Infinite Elements, Perfectly Matched Layers, and Absorbing Layers

Simulation of Infinite Domains

Simulation of unbounded or infinite domains is a challenge encountered in many types of physics. Normally, any physics simulates a process within a bounded domain represented by the geometry drawn in, or imported into, COMSOL Multiphysics. But the domain is often delimited by artificial boundaries inserted to limit the extent of the model to a manageable *region of interest*. You might not be interested in the details of the solution far away from any sources, loads, or material inhomogeneities, but the solution inside the region of interest must not be affected by the presence of the artificial boundaries. You simply want it to behave as if the domain was of infinite extent. In general, for field problems, unless the boundaries of the simulated device correspond to well-defined boundary conditions (such as a constant electric potential), then you need to include sufficient surrounding volume, so that the external boundaries of the computational space can be specified in a way that does not interfere with computations of the correct fields in or on the device that you are modeling.

Artificial truncation of the domain can be handled in several ways. Some physics interfaces include special boundary conditions to absorb outgoing propagating waves without spurious reflections, so-called low-reflecting boundary conditions. Others allow impedance boundary conditions, which can account for a finite impedance between the model boundary and a reference at infinity. Such boundary conditions are often efficient and useful but lack some generality and sometimes accuracy.

Another way to accomplish the same desired effect is to apply a coordinate scaling to a layer of virtual domains surrounding the physical region of interest. For stationary and transient problems, these virtual domains can be stretched out toward infinity, giving rise to *infinite elements*. To absorb outgoing waves in a frequency-domain problem, you must instead stretch the virtual domains into the complex plane, creating so-called *perfectly matched layers* (PMLs). In addition, for transient problems using a time-explicit solver, you can add an *absorbing layer*, which acts like an effective nonreflecting-like boundary conditions.

The Infinite Element Domain, Perfectly Matched Layer, and Absorbing Layer nodes are only available with the following add-on products for applicable physics interfaces:

- Infinite Element Domain: AC/DC Module, Structural Mechanics Module, MEMS Module, Heat Transfer Module, Chemical Reaction Engineering Module, Subsurface Flow Module, Batteries & Fuel Cells Module, Electrodeposition Module, Corrosion Module, Electrochemistry Module, and Plasma Module.
 - Perfectly Matched Layer: Acoustics Module, RF Module, Wave Optics Module, Structural Mechanics Module, and MEMS Module,
 - Absorbing Layer: Acoustics Module, RF Module, and Wave Optics Module
-

Because of their common background as coordinate stretching, infinite elements and PMLs in COMSOL Multiphysics share a number of important properties. They share part of the user interface and many modeling principles can be translated directly from one to the other. In the description below, infinite elements and PMLs are therefore sometimes referred to collectively as *scaling systems*.

The [Scaling System](#) node provides direct access to coordinate transformation machinery underlying PMLs and infinite elements.

Standard Geometry Configurations

Automatic scaling systems are available in COMSOL Multiphysics for three distinct geometrical configurations: **Cartesian**, **Cylindrical**, and **Spherical**. Which ones you can use depends on the space dimension of the Component.

The choice of a Cartesian, cylindrical or spherical configuration depends on the shape of your corresponding 3D geometry outline (box, cylinder, or sphere). It has no formal connection to what base coordinate system your geometry is using (but Cartesian configurations will never apply in 2D axisymmetry, and spherical configurations will never apply in planar 2D for obvious reasons).

Plane 2D Models

The available scaling types in plane 2D models are **Cartesian** and **Cylindrical**. Cartesian domains are stretched in one or two directions depending on whether they are attached to an edge or to a corner of the physical region of interest.

It is important that separate, normally quadratic, domains are drawn at the corners.

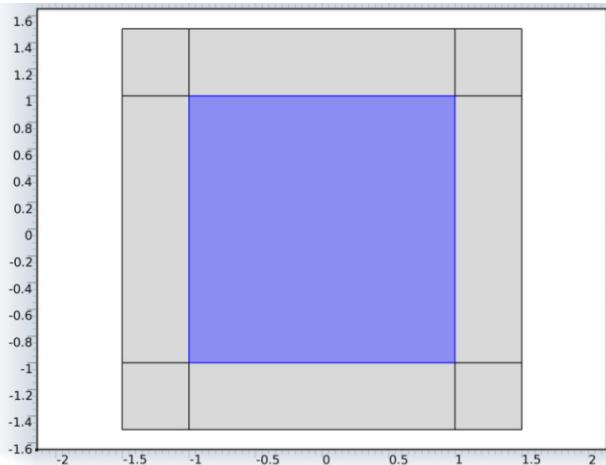

Figure 5-6: Typical Cartesian scaling configuration. Note the distinction between edge and corner domains.

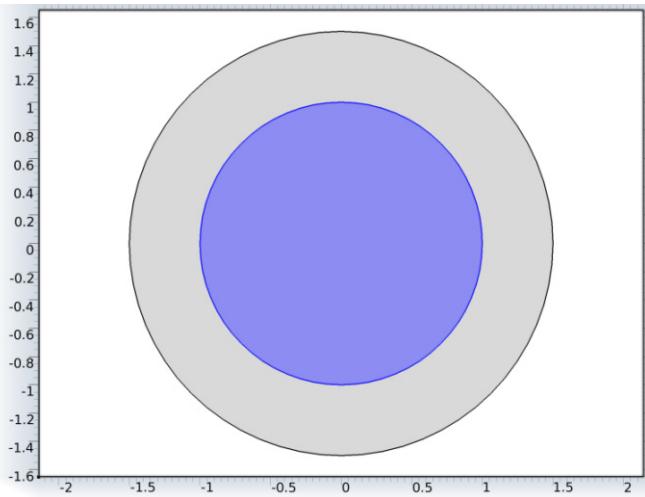

Figure 5-7: Example of cylindrical scaling configuration in plane 2D. You must specify the center point of the model when different from the origin of the coordinate system.

AXISYMMETRIC 2D MODELS

The available scaling types in 2D axisymmetric models are **Cylindrical** and **Spherical**. The axisymmetric cylindrical configuration, from the practical point of view, behaves identically to the plane 2D Cartesian option. Similarly, the axisymmetric spherical scaling is similar to plane 2D cylindrical scaling, except that it is always centered on the axis.

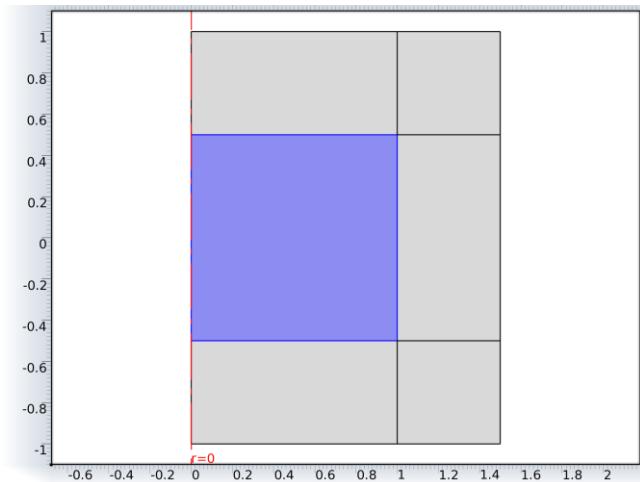

Figure 5-8: Axisymmetric cylindrical scaling uses domains of three distinct types: with radial stretching, with axial stretching, and with both radial and axial stretching. The latter are the corner zones, which must be drawn as distinct domains.

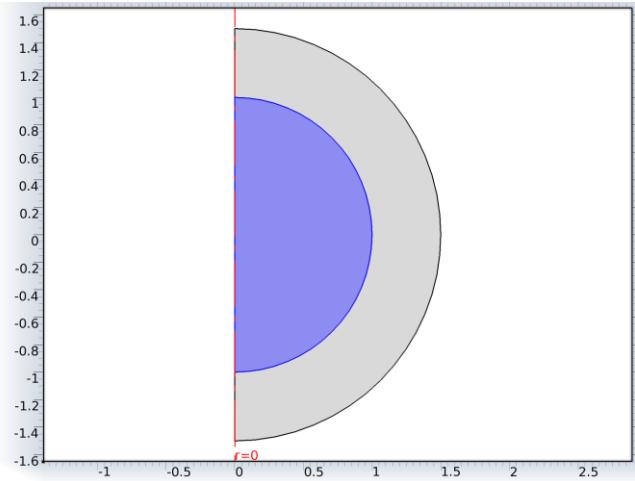

Figure 5-9: Axisymmetric spherical scaling assumes radial stretching in an annulus centered at a point on the axis. If the centerpoint is not the origin of the coordinate system, you must specify its axial position.

3D MODELS

The available scaling types in 3D are **Cartesian**, **Cylindrical** and **Spherical**. The Cartesian scaling domains are of three different types. Depending on whether they are attached to a surface, an edge, or a point in the physical domain, they are stretched in one, two, or three directions, respectively. Cylindrical scaling domains are also of three different types: radially stretched, axially stretched, and stretched both radially and axially. Spherically scaled domains are always stretched only in the spherical domain's radial direction.

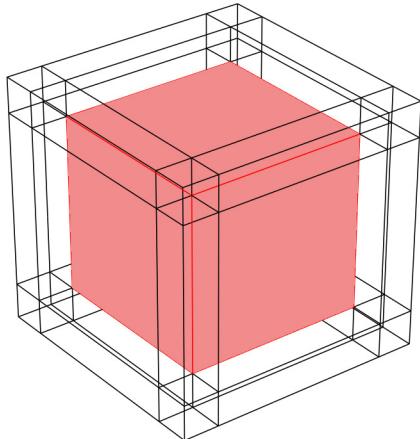

Figure 5-10: There are three different types of Cartesian scaling domain, attached to faces, edges and corners, respectively. They differ in the number of scaled directions. Note that the edge and corner zones must be drawn as distinct domains in the geometry.

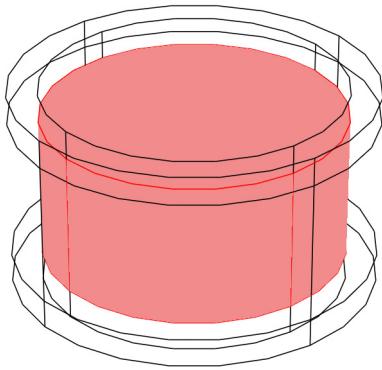

Figure 5-11: The three different types of cylindrical scaling domain are attached to the sides, top and bottom, and edges of the cylindrical physical domain. The position and orientation is specified as a center point and an axial direction. The scaling system domains are stretched in the radial direction, away from the axis, in the axial direction, and in both radial and axial direction, respectively.

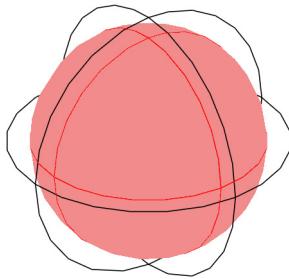

Figure 5-12: A spherical scaling domain stretches the coordinate system only in the radial direction relative to a specified center point.

Manual Settings for Nonstandard Geometries

The automatic geometry analysis performed for each of the standard cases shown above may fail for certain geometry configurations. In particular, the analysis assumes that there are no inactive domains present on the outside of the scaling domain — that is, that the only domains adjacent to the scaling domain belong to the region of interest for the simulation. This is not always the case, for example, when you want to perform a simulation on a subset of a CAD geometry.

When the automatic geometry analysis fails, it is possible to instead specify the stretching directions in each domain manually. First, select the number of stretching directions: one, two, or three. Then, for each stretching direction, enter a scalar function of position, $d_i(\mathbf{x})$, defined such that it measures the distance from the inner scaling domain boundary in the given stretching direction. Also enter the maximum distance for each direction, $d_{\text{Max},i}$ — effectively the thickness of the scaling domain in the given direction.

Stretching functions, $f_i(\xi)$, are evaluated as functions of the dimensionless distance $\xi_i = d_i(\mathbf{x})/d_{\text{Max},i}$. The result is interpreted as a stretched distance in the given stretching direction. Finally, the change in distance is multiplied with the stretching direction unit vector, which is computed as the gradient of the corresponding distance function, to

produce a stretching displacement relative to the original position. This is done for each stretching direction separately such that the scaled coordinate vector \mathbf{x}' is

$$\mathbf{x}' = \mathbf{x} + \sum_i \lambda \left(f_i \left(\frac{d_i(\mathbf{x})}{d_{\text{Max},i}} \right) - d_i(\mathbf{x}) \right) \nabla d_i(\mathbf{x})$$

where λ is a typical wavelength in PML domains, and equal to 1 in infinite elements.

Note on Availability

Infinite elements and perfectly matched layers are available only for some physics and when COMSOL Multiphysics is used together with certain add-on modules. If you have not added any physics that is compatible with infinite elements or perfectly matched layers under the available licenses, you cannot add such features to the model.

Further, after turning a domain into a PML or infinite element, that domain is not allowed in the active selection of physics interfaces and individual nodes that are not compatible with these special domain types. This means that the scaled domains are either not selectable at all or display as **Not applicable** in the selection list.

PML Implementation

PMLs apply a complex coordinate stretching in one, two, or three directions, depending on how the PML domain connects to the physical domain. In each direction, the same form of stretching is used, defined as a function of a dimensionless coordinate ξ , which varies from 0 to 1 over the PML layer. The function returns a new, complex and stretched, coordinate interpreted as relative to the typical wavelength for each simulation frequency. That is, the complex displacement for stretching in a single direction is $\Delta\mathbf{x} = \lambda f_i(\xi) - \Delta_w \xi$, where λ is a typical wavelength and Δ_w is the original width of the PML (as drawn in the geometry). A separate displacement is computed for each stretching direction and summed to make a total displacement.

In the PML nodes, you can choose between predefined *polynomial* and *rational* stretching functions, or select your own *user-defined* functions. The polynomial stretching function is defined as

$$f_p(\xi) = s \xi^p (1 - i)$$

where p is a *curvature parameter*, and s is a *scaling factor*. The rational stretching function is defined as

$$f_r(\xi) = s \xi \left(\frac{1}{3p(1 - \xi) + 4} - \frac{i}{3p(1 - \xi)} \right)$$

where p and s are again a curvature parameter and a scaling factor, respectively.

For user-defined stretching, you specify the real and imaginary parts of $f(\xi)$ as separate functions of one or two arguments. The first argument is interpreted as the dimensionless distance ξ and the second — optional — argument as the typical wavelength λ .

There is no check that the geometry of the region is correct, so it is important to draw a proper geometry and select the corresponding region type.

For more information about the use of PMLs in acoustics simulations, see *Perfectly Matched Layers (PMLs)* in the *Acoustics Module User's Guide*.

INTERPRETING PML PARAMETERS

The predefined PML coordinate stretching functions are controlled by three parameters:

- The *typical wavelength* represents the longest wavelength of propagating waves in an infinite medium. It is normally provided by a physics interface. For nondispersive media, it is expected to be inversely proportional to the frequency and serve to make the PML perform similarly for all frequencies.

In eigenfrequency studies, the typical wavelength parameter must not depend on the — unknown — frequency. When the typical wavelength is set to be obtained from a physics interface, it is therefore redefined to be equal to the PML width Δ_w instead. A user-defined typical wavelength applies as entered, but must not be a function of the frequency. It is often most convenient to draw and mesh the PML as if it had been part of the physical domain. To tune its effective thickness, use the scaling factor.

- The PML *scaling factor* multiplies the *typical wavelength* to produce an effective scaled width for the PML. For example, to retain perfect absorption for plane waves incident at an angle θ relative to the boundary normal, it is necessary to compensate for the longer wavelength seen by the PML in the stretching direction. In this case, $1/\cos(\theta)$ is a suitable scaling factor.

Conversely, if resolving the field inside the PML proves too costly, it is possible to lower the scaling factor below its default value 1, to make better use of the available mesh elements. Note that this has a price in terms of less efficient absorption.

- The PML *curvature* parameter serves to relocate mesh resolution inside the PML. When there are components present which decay inside the PML much faster than the longest waves, the resolution must be increased in the zone closest to the boundary between PML and physical domain. Increasing the curvature parameter effectively moves available mesh elements toward the inner PML boundary. This is often necessary when the wave field contains a mix of different wavelengths or a mix between propagating and evanescent components.

If you increase the curvature factor, you must normally still resolve the long propagating waves sufficiently, so an overall increase of the number of mesh elements across the PML is called for.

CHOOSING A STRETCHING TYPE

Which coordinate stretching type is most appropriate depends on the problem at hand. Consider the following when choosing between polynomial and rational stretching:

Polynomial The polynomial stretching strategy makes a minimum of assumptions about the wave field incident on the PML. Its finite and equal real and imaginary parts mean that propagating and evanescent waves with the same length scale are treated alike. The default scaling factor gives a PML with a maximum attenuation of about 109 dB for normal incidence and provided sufficient mesh resolution.

The polynomial stretching is generally applicable and most appropriate when there is a mix of different wave types in the model and you can afford at least 8 mesh elements across the PML. Also, compared to the rational stretching, it interferes less with the convergence of iterative linear solvers.

Rational The rational stretching is designed for propagating waves of mixed wavelengths and angles of incidence. The real part of the stretching scales the effective PML thickness to a quarter of a typical wavelength, while the imaginary part — responsible for the attenuation — is stretched out toward infinity. This means that provided sufficient mesh resolution, the PML absorbs any propagating wave perfectly.

User defined If none of the above stretching types are suitable, you can specify a user-defined stretching using functions that you add to the model as the real and imaginary parts of the stretching function.

In reality, the mesh resolution limits the effectiveness of the rationally stretched PMLs. For a single wavelength at normal incidence, 3 mesh elements across the PML normally give sufficient attenuation and accuracy. If the wave field contains also longer- or shorter-wavelength components, the mesh resolution must be increased. When other wave components are shorter than the supplied typical wavelength, increasing the curvature factor may be useful to make best use of the available resolution.

PMLs in Multiphysics

The coordinate stretching used in the PMLs is by default controlled by one of the physics interfaces in the model, which provides a *typical wavelength*. If each PML region contains a single active physics, and the PML regions are disjoint, you can set up separate PML nodes and choose different physics interfaces as wavelength source. If, instead, there are multiple physics active in the same PML domains or in adjacent domains — such as when an air-water interface extends into the PML — you must choose a single typical wavelength. Either choose a wavelength provided by one of the interfaces, or set a user-defined wavelength.

The way the stretching functions are defined, it usually makes the most sense to select the longest wavelength of propagating waves actually excited and propagating into the PML. Any shorter wavelengths must be accounted for by increasing the mesh resolution and curvature factor in the PML.

In the Acoustics Module, MEMS Module, and Structural Mechanics Module, you can control the typical wavelength passed from the physics interface to the PML, by changing the **Typical Wave Speed** property in the physics interface's **Settings** window. The default wave speed generally corresponds to a compressional or pressure wave, which is the fastest wave type and therefore of longest wavelength. In the RF Module, the default for the typical wavelength is $2\pi/k$, where k is the local wave number.

Perfectly Matched Layer

A **Perfectly Matched Layer** node () applies a complex coordinate scaling to a layer of virtual domains surrounding the physical region of interest. When appropriately tuned, this layer absorbs all outgoing wave energy in frequency-domain problems, without any impedance mismatch — causing spurious reflections — at the boundary.

To add a Perfectly Matched Layer to any Component, then in the **Definitions** toolbar, click **Perfectly Matched Layer**, or right-click the **Definitions** node under the Component and choose **Perfectly Matched Layer**. If the nodes under the **Component** node are grouped by type, instead right-click  **Domain Properties** under **Definitions**.

SETTINGS

The **Label** is the default perfectly matched layer name.

The default **Name** (for the first perfectly matched layer in the model) is `pml1`. The **Name** provides a namespace for variables created by the **Perfectly Matched Layer** node. For example, the scaled x coordinate can typically be accessed in equations and postprocessing as `pml1.x`. See the **Equation View** subnode for a complete list of available variables.

To display the **Equation View** node under all nodes creating variables, click the **Show** button and select **Equation View**. See also [Equation View](#).

DOMAIN SELECTION

Select a set of domains conforming to the selected geometry type. See [Standard Geometry Configurations](#).

GEOMETRY

Select a **Type**: **Cartesian** (the default), **Spherical**, **Cylindrical**, or **User defined**.

- If **Spherical** is selected, enter the position of the center of the spherical geometry in the **Center coordinate** table. For axisymmetric models, only the z coordinate is required since the geometry must be centered on the axis.
- If **Cylindrical** is selected, enter the position of a point on the cylinder axis in the **Center coordinate** table. For 3D models, also enter a **Center axis direction** vector.
- If **User defined** is selected, first choose the **Number of stretching directions** appropriate for the geometrical configuration. Then for each stretching direction specify a **Distance function**, evaluating to the distance from the inner boundary of the PML measured in the stretching direction, and the **Thickness** of the PML in the same direction.

Each of these types (except the user-defined type) requires certain geometrical configurations and not all of them are available for all space dimensions.

SCALING

Select a **Coordinate stretching type**: **Polynomial** (the default), **Rational**, or **User defined**. See [PML Implementation](#) for help on making a decision.

Select an option from the **Typical wavelength from** list: **Physics interface** (the default) or **User defined**. If **Physics interface** is selected, select one of the interfaces supporting PMLs from the **Physics** list. If **User defined** is selected, enter a value or expression for the **Typical wavelength**. The default is 1.

The **Physics interface** setting has no effect in Eigenfrequency studies. In that case, the typical wavelength is redefined to be equal to the PML width, as drawn in the geometry. The **User defined** option applies unaltered.

When using the PML in the **Pressure Acoustics, Transient** interface, then if you change the **Typical wavelength from** option to **User defined**, it is not the actual wavelength that should be entered but rather the speed of sound per Hertz. For example, if **User defined** is selected in a normal air domain, then enter $343[\text{m/s}]/1[\text{Hz}]$. The reason is that in the time domain the PML formulation is not related to wavelength but to speed of sound. Transient signals typically include many Fourier frequency components. For the implementation related to the time domain see the [Theory for the Perfectly Matched Layers in the Time Domain](#) section in the *Acoustics Module User's Guide*.

For the predefined **Polynomial** and **Rational** stretching types, enter a value or expression for the **PML scaling factor** and the **PML scaling curvature parameter** which can be used to tune the PMLs for wave fields with evanescent components or wavelengths deviating from the free-space wavelength of plane waves. See further [PML Implementation](#). The defaults are 1 for both.

For the **User defined** stretching type, select **Real part of stretching function** and **Imaginary part of stretching function** from functions defined under **Global>Definitions** or under **Definitions** in a component, or leave the default value **None**, which for the real part is interpreted as $f(\xi) = \xi$ and for the imaginary part as $f(\xi) = 0$. Any function node defining a single function of one or two arguments is eligible for use as a stretching function. The first argument is

interpreted as a dimensionless distance, ξ , in the range 0 to 1, and the second argument — if present — as the typical wavelength.

	If you have the Acoustics Module, see these examples: <ul style="list-style-type: none">• <i>Cylindrical Subwoofer</i>: Application Library path Acoustics_Module/Tutorials/cylindrical_subwoofer• <i>Acoustic Scattering off an Ellipsoid</i>: Application Library path Acoustics_Module/Tutorials/acoustic_scattering
	If you have the RF Module, see these examples: <ul style="list-style-type: none">• 2D, cylindrical PML — <i>Radar Cross Section</i>: Application Library path RF_Module/Scattering_and_RCS/radar_cross_section• 3D, spherical PML with swept mesh — <i>RF Coil</i>: Application Library path RF_Module/Passive_Devices/rf_coil

Known Issues When Modeling Using PMLs

When modeling with PMLs be aware of the following:

USE OF ONE SINGLE PERFECTLY MATCHED LAYER NODE

A separate Perfectly Matched Layer node must be used for each simply connected PML region. That is, to use one and the same Perfectly Matched Layer node, all PML domains must be in contact with each other. Otherwise the PMLs do not work properly.

ELEMENT QUALITY

The coordinate scaling resulting from PMLs also yields an equivalent scaling of the mesh that can effectively result in a poor mesh element quality. (The element quality displayed by the mesh statistics does not account for this effect.) This typically happens when the geometrical thickness of the PML deviates much from one wavelength (local wavelength rather than free space wavelength). The poor element quality causes poor convergence for iterative solvers and makes the problem ill-conditioned in general.

For this reason, it is strongly recommended that you use swept meshing in the PML domains. The *vector element* formulations (the ones using two or more components of a vector field variable) in the RF Module are particularly sensitive to low element quality. The sweep direction should be selected the same as the direction of scaling. For Cartesian PMLs and regions with more than one direction of scaling, it is recommended to first sweep the mesh in the domains with only one direction of scaling, then sweep the domains with scaling in two directions, and finish by sweeping the mesh in the domains with PML scaling in all three directions.

COMPLICATED EXPRESSIONS

The expressions resulting from the stretching get quite complicated for spherical PMLs. This increases the time for the assembly stage in the solution process. After the assembly, the computation time and memory consumption is comparable to a problem without PMLs. The number of iterations for iterative solvers might increase if the PML regions have a coarse mesh.

ERRONEOUS RESULTS

PML regions deviating significantly from the typical configurations shown in the beginning of this section can cause the automatic calculation of the PML parameter to give erroneous results.

USE THE SAME MATERIAL PARAMETERS OR BOUNDARY CONDITIONS

The PML region is designed to model uniform regions extended toward infinity. Avoid using objects with different material parameters or boundary conditions that influence the solution inside a PML region.

Infinite Element Implementation

Infinite elements apply a semi-infinite coordinate stretching in one, two, or three directions, depending on how the infinite element domain connects to the physical domain. In each direction, the same form of stretching is used, defined as a function of a dimensionless coordinate ξ , which varies from 0 to 1 over the infinite element layer. The function returns a new, stretched, coordinate interpreted as a new position in the given direction. That is, the displacement for stretching in a single direction is $\Delta\mathbf{x} = f_i(\xi) - \Delta_w\xi$, where Δ_w is the original width of the infinite element domain (as drawn in the geometry). A separate displacement vector is computed for each stretching direction and summed to make a total displacement.

The default rational stretching function is defined as

$$f(\xi) = \frac{\xi}{\gamma - \xi} \Delta_p \quad (5-1)$$

where Δ_p is the, so called, pole distance and γ is a number larger than one, computed as

$$\gamma = \frac{\Delta_s + \Delta_p}{\Delta_s}$$

where Δ_s is the scaled thickness of the infinite element domain. The scaled thickness Δ_s and the pole distance Δ_p are user inputs.

For the user-defined stretching option, you specify $f(\xi)$ directly as a functions of the dimensionless distance ξ . This can, for example, be used for modeling a surrounding domain of finite extent, or for implementing a stretching function that better fits a dependent variable that decays with distance slower or faster than a monopole solution.

There is no check that the geometry of the region is correct, so it is important to draw a proper geometry and select the corresponding region type.

INTERPRETING INFINITE ELEMENT PARAMETERS

The default infinite element stretching has two user-defined parameters that let you control the thickness of the quasi-infinite region, as perceived by the physics interfaces, as well as how the stretching is distributed across the domain.

Physical width The scaled width of the infinite element domain, Δ_s , is by default set to $1e3*dGeomChar$, where the constant $dGeomChar$ is a characteristic geometry dimension. The domain is therefore by default scaled to be very much larger than the original geometry, but not quite infinite in order to avoid numerical difficulties. In particular, the finite distance to the far-away boundary allows prescribing standard boundary conditions effectively at infinity.

Pole distance The coordinate stretching function, [Equation 5-1](#), used in the infinite element domain contains a singularity when $\xi = \gamma$. Since $\gamma > 1$, this happens outside the infinite element domain. The pole distance, Δ_p , controls just how far away this singularity is located. If Δ_p is small compared to the scaled width, Δ_s , the coordinate stretching is very nonlinear, progressing from gentle close to the boundary with the physical domain to abrupt toward the quasi-infinite boundary. Conversely, if the pole distance is large compared to the scaled width, the stretching is constant across the domain.

The default pole distance is `dGeomChar`, which is small compared to the physical width. Therefore, the coordinate stretching by default exhibits a nearly $1/r$ behavior, which is suitable for making optimal use of mesh resolution when the dependent variable also behaves as $1/r$ for large r , where r is the distance from any sources or inhomogeneities.

Infinite Element Domain

An **Infinite Element Domain** node () applies a real-valued coordinate scaling to a layer of virtual domains surrounding the physical region of interest. When the dependent variables vary slowly with radial distance from the center of the physical domain, the finite elements can be stretched in the radial direction such that boundary conditions on the outside of the infinite element layer are effectively applied at a very large distance from any region of interest.

To add an Infinite Element Domain to any Component, click **Infinite Element Domain** in the **Definitions** toolbar, or right-click the **Definitions** node under the Component and choose **Infinite Element Domain**. If the nodes under the **Component** node are grouped by type, instead right-click  **Domain Properties** under **Definitions**.

SETTINGS

The **Label** is the default infinite element domain name.

The default **Name** (for the first infinite element domain in the model) is `ie`. The **Name** provides a namespace for variables created by the **Infinite Element Domain** node. For example, the scaled x coordinate can typically be accessed in equations and postprocessing as `ie1.x`. See the **Equation View** subnode for a complete list of available variables.

To display the **Equation View** node under all nodes creating variables, click the **Show** button and select **Equation View**. See also [Equation View](#).

DOMAIN SELECTION

Select a set of domains conforming to the selected geometry type. See [Standard Geometry Configurations](#).

GEOMETRY

Select a **Type**: **Cartesian** (the default), **Spherical**, **Cylindrical**, or **User defined**.

- If **Spherical** is selected, enter the position of the center of the spherical geometry in the **Center coordinate** table. For axisymmetric models, only the z coordinate is required since the geometry must be centered on the axis.
- If **Cylindrical** is selected, enter the position of a point on the cylinder axis in the **Center coordinate** table. For 3D models, also enter a **Center axis direction** vector.
- If **User defined** is selected, first choose the **Number of stretching directions** appropriate for the geometrical configuration. Then for each stretching direction specify a **Distance function**, evaluating to the distance from the inner boundary of the infinite element domain measured in the stretching direction, and the **Thickness** of the domain in the same direction.

Each of these types (except the user-defined type) requires certain geometrical configurations and not all of them are available for all space dimensions.

SCALING

Select a **Coordinate stretching type**: **Rational** (the default) or **User defined**. See [Infinite Element Implementation](#) for a detailed explanation of the options.

For the default **Rational** stretching type, enter expressions for the **Physical width** (SI unit: m) and the **Pole distance** (SI unit: m). The default values, $1e3*dGeomChar$ and $dGeomChar$, respectively, lead to an infinite element domain that is very large compared to the geometry dimensions and with a nearly singular $1/r$ stretching.

For the **User defined** stretching type, select a **Stretching function** from functions defined under **Global>Definitions** or under **Definitions** in a component, or leave the default value **None**, which is interpreted as $f(\xi) = \xi$. Any function node defining a single function of one arguments is eligible for use as a stretching function. The argument is interpreted as a dimensionless distance, ξ , in the range 0 to 1.

	If you have the AC/DC Module, see this example: <i>Modeling of a 3D Inductor:</i> Application Library path ACDC_Module/Inductive_Devices_and_Coils/inductor_3d
	If you have the Batteries & Fuel Cells Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module see this example: <i>Voltammetry at a Microdisk Electrode:</i> Application Library path Batteries_and_Fuel_Cells_Module/General_Electrochemistry/microdisk_voltammetry, Corrosion_Module/General_Electrochemistry/microdisk_voltammetry, Electrochemistry_Module/Electroanalysis/microdisk_voltammetry, Electrodeposition_Module/Tutorials/microdisk_voltammetry

Known Issues When Modeling Using Infinite Elements

Be aware of the following when modeling with infinite elements:

USE OF ONE SINGLE INFINITE ELEMENTS NODE

Use a separate Infinite Elements node for each isolated infinite element domain. That is, to use one and the same Infinite Elements node, all infinite element domains must be in contact with each other. Otherwise the infinite elements do not work properly.

ELEMENT QUALITY

The coordinate scaling resulting from infinite elements also yields an equivalent stretching or scaling of the mesh that effectively results in a poor element quality. (The element quality displayed by the mesh statistics does not account for this effect.)

The poor element quality causes poor or slow convergence for iterative solvers and makes the problem ill-conditioned in general. The *vector element* formulations (the ones using two or more components of a vector field variable) in the AC/DC Module are particularly sensitive to low element quality.

For this reason, it is strongly recommended to use swept meshing in the infinite element domains. Select the sweep direction to be the same as the direction of scaling. For Cartesian infinite elements in regions with more than one direction of scaling it is recommended to first sweep the mesh in the domains with only one direction of scaling, then sweep the domains with scaling in two directions, and finally sweep the mesh in the domains with infinite element scaling in all three directions.

COMPLICATED EXPRESSIONS

The expressions resulting from the stretching get quite complicated for spherical infinite elements in 3D. This increases the time for the assembly stage in the solution process. After the assembly, the computation time and memory consumption is comparable to a problem without infinite elements. The number of iterations for iterative solvers might increase if the infinite element regions have a coarse mesh.

ERRONEOUS RESULTS

Infinite element regions deviating significantly from the typical configurations shown in the beginning of this section can cause the automatic calculation of the infinite element parameter to give erroneous results.

USE THE SAME MATERIAL PARAMETERS OR BOUNDARY CONDITIONS

The infinite element region is designed to model uniform regions extended toward infinity. Avoid using objects with different material parameters or boundary conditions that influence the solution inside an infinite element region.

Absorbing Layer

An **Absorbing Layer** node () adds an absorbing layer to a time-explicit simulation. Absorbing layers are often referred to as sponge layers. The absorbing layers work by combining three techniques: a scaling system, filtering, and simple nonreflecting conditions. The Absorbing Layer node adds a special scaled system, where the scaling effectively slows down the propagating waves. Filtering attenuates and filters out high frequency components of the wave. In the Convected Wave Equation, Time Explicit interface (in the Acoustics Module), you can specify filter parameters in the **Filter Parameters in Absorbing Layers** section of its Settings window. See also [Filter Parameters](#) for the Wave Form PDE.

To add an Absorbing Layer any Component, then in the **Definitions** toolbar, click **Absorbing Layer**, or right-click the **Definitions** node under the Component and choose **Absorbing Layer**. If the nodes under the **Component** node are grouped by type, instead right-click  **Domain Properties** under **Definitions**.

SETTINGS

The **Label** is the default absorbing layer name.

The default **Name** (for the first absorbing layer in the model) is **ab**. The **Name** provides a namespace for variables created by the **Absorbing Layer** node. For example, the scaled *x* coordinate can typically be accessed in equations and postprocessing as **ab1.x**. See the **Equation View** subnode for a complete list of available variables.

To display the **Equation View** node under all nodes creating variables, click the **Show** button and select **Equation View**. See also [Equation View](#).

DOMAIN SELECTION

Select a set of domains conforming to the selected geometry type. See [Standard Geometry Configurations](#).

GEOMETRY

Select a **Type**: **Cartesian** (the default), **Spherical**, **Cylindrical**, or **User defined**.

- If **Spherical** is selected, enter the position of the center of the spherical geometry in the **Center coordinate** table. For axisymmetric models, only the *z* coordinate is required since the geometry must be centered on the axis.
- If **Cylindrical** is selected, enter the position of a point on the cylinder axis in the **Center coordinate** table. For 3D models, also enter a **Center axis direction** vector.
- If **User defined** is selected, first choose the **Number of stretching directions** appropriate for the geometrical configuration. Then for each stretching direction specify a **Distance function**, evaluating to the distance from the inner boundary of the absorbing layer measured in the stretching direction, and the **Thickness** of the domain in the same direction.

SCALING

Enter expressions for the **Physical width** (SI unit: m) and the **Pole distance** (SI unit: m). The default values are `2.0*dGeomChar` and `0.25*dGeomChar`, respectively. For the layers to work optimally, the filter should not be too aggressive. Moreover, the scaled coordinates in the layer domain should also vary smoothly. To inspect the scaled system, you can plot the coordinate variables `x_absorb_ab1`, `y_absorb_ab1`, and `z_absorb_ab1` (for an Absorbing Layer node `ab1`). Using the absorbing layers with the three combined techniques will enable the reduction of spurious reflections by a factor between 100 and 1000 compared to the incident amplitude.

If you have the Acoustics Module, see this example:

Gaussian Pulse in 2D Uniform Flow: Convected Wave Equation and Absorbing Layers:
Application Library path **Acoustics_Module/Tutorials/gaussian_pulse_absorbing_layers**

Reduced Models

Introduction

Reduced models are online reduced-order representations of a full COMSOL Multiphysics model, which can be created by a **Model Reduction** study step (see [Model Reduction](#)) or imported from a COMSOL Reduced Model file (*.mphrom). Here, *online* refers to using the reduced models for evaluations rather than producing them. You can store and use reduced-order models separately in a COMSOL Multiphysics model. Such reduced models can be useful for applications such as:

- Effective system simulations (such as control system simulations and circuit simulations)
- PSD (power spectral density) and random response models (reduced models)
- Optimization (surrogate models)
- Applications in general, which can run faster and leaner based on a reduced model instead of a full model.

Reduced Model Inputs

A Reduced Model is essentially a black box with a number of inputs and a number of outputs which as been constructed, or *trained*, using a full COMSOL model so as to return the same output values as the full model for inputs within some allowed range. During the training phase, the model reduction process must be able to evaluate the dependency of outputs on inputs. Such dependency evaluations can only be performed in general with respect to degrees of freedom in the model.

Therefore, any quantity that you want to use as input to a Reduced Model must be defined as a degree of freedom during the training phase. And it must also evaluate to a constant training value, independent of time or frequency. At the same time, it should behave like a normal user-defined variable when the full model is computed or when the Reduced Model is called *online*. For example, it can be time- or frequency-dependent in that situation.

Reduced model inputs are special variables which have these desired properties: they are defined by an online expression during normal computations, where they can be used exactly like any other user-defined variable. But they are internally redefined as degrees of freedom when necessary for training a Reduced Model. The Model Reduction study step (see [Model Reduction](#)) allows only such predefined reduced model inputs as inputs to the training process.

Global Reduced Model Inputs

Add a **Global Reduced Model Inputs** node () under **Global Definitions** to declare global variables for use as controlling inputs to Reduced Model nodes. You add it by right-clicking **Global Definitions** and choosing **Global Reduced Model Inputs** from the **Reduced Model Inputs** submenu.

REDUCED MODEL INPUTS

Specify a **Control name** and online **Expression** for each required input. There are two possibilities: either enter the name of an existing model parameter, or select a new name. Entering the name of an existing model parameter will redefine that parameter as a reduced model input with the online expression linked from the parameters original definition in a Parameters node. In this case, the **Expression** column immediately displays the linked expression and is not editable. If you instead select a new name, you must also enter an online expression which will define the value of the input variable in all situations except during training of a reduced model (see [Reduced Model](#)).

Importing Reduced Models

You can save reduced models to file as COMSOL Reduced Model files, which are variants of the normal COMSOL Model MPH-files but with a reduced model and the extension **.mphrom**. To import such COMSOL Reduced Model files, right-click the **Reduced Models** node and choose **Reduced Models Import**. A **Select File** dialog box then appears, and you can browse and choose a **COMSOL Reduced Model (*.mphrom)** model from the file system.

Reduced Model

A **Reduced Model** node () contains an online reduced model. The model could have been created in the same session or imported from a COMSOL Reduced Model file. A reduced model can be used, if applicable, as part of a time-dependent or frequency domain study, and it can be used for reconstruction of the full model from a compact, reduced model.

The following buttons are available at the top of the **Settings** window (or right-click the **Reduced Model** node and choose them from the **Reduced Model** context submenu):

Click **Update Reduced Model Data** () (or press F5) to update the reduced model data to take the current model state into account.

It is only possible to update the reduced model data if the data has not been cleared and when the generating study has not been removed.

Choose **Export Reduced Model** () to export the reduced-order model to a COMSOL Reduced Model file (*.mphrom) that you specify in the **Export** dialog box.

It is only possible to export linear models with data that has not been cleared.

Click **Reset to Default** () to reset the reduced model properties to the default values (that is, the last values produced from a **Model Reduction** node or imported). Clicking this button is useful if you have made edits for the settings that you do not want to keep. When updating the reduced model using the new settings, the updated values become the ones used as the original values for the reset.

It also possible to duplicate a **Reduced Model** node (by right-clicking and choosing **Duplicate** or pressing Ctrl+Shift+D).

The online use of a reduced model includes the following steps:

- 1 Select the model to use or import one from a COMSOL Reduced Model file (which then shows up as a **Reduced Model** node under **Reduced Models**).
- 2 Define values for parameters and expressions for model controls, which could be a connection to another model.
- 3 Set up connections, plots, or expressions using the model outputs.
- 4 Configure reconstruction for dependent variables not solved for in a time-dependent or frequency domain study.
- 5 Perform online simulations using the reduced model to produce outputs similar to function evaluations.
Required inputs must be provided.
- 6 Postprocessing the controls and outputs and possibly reconstructed states.
- 7 Storing and exporting the results.

The **Settings** window for a **Reduced Model** node contains the following sections:

PARAMETERS

Here you define the parameters for the reduced model. The **Time** (default: `t`) for time-dependent models or the **Frequency** (default: `freq`) for a frequency-domain model.

MODEL CONTROLS INPUTS

The list in this section contains the model control inputs defined in the corresponding **Model Reduction** node's **Model Control Inputs** section (such as some global parameter). Also, the load factor, which is defined in the **Modal Solver** node's **Advanced** section always appears in this list for modal models. If desired, you can redefine the expressions for the inputs and their variable names in the **Expression** column and the **Variable** column, respectively. The defined names can then be used in postprocessing, for example.

OUTPUTS

The list in this section contains the outputs defined in the corresponding **Model Reduction** node's **Outputs** section (a probe variable, for example). If desired, you can redefine their variable names in the **Variable** column. The defined names can then be used in postprocessing, for example. If you have not defined a variable name in the **Model Reduction** node, the output variables use default variable names such as `rom1.mr.out1`.

Select the **Add output dependent variables** check box to add dependent variables corresponding to the output variables. The dependent variables are added to the **Dependent variables** column. Such dependent variables also appear in the main study node that is used for the reduced model. For example, in a **Time Dependent** study node, in the **Physics and Variables Selection** section, the dependent variables from the reduced model appear under **Reduced model**. Select the check boxes in the **Store output dependent variables** column to store those dependent variables in the output from the study for use in postprocessing, for example.

ONLINE SETTINGS

These settings affect the internal solver for the model reduction.

The **State reconstruction** check box is only available if you have selected the **Enable reconstruction capability** check box in the **Model Reduction** node's **Model Reduction Settings** section. Select it to use state reconstruction for the dependent variables in the table below.

State reconstruction is not possible in a **Reduced Model** node that uses reduced-order model data saved in a COMSOL Reduced Model file and then imported. The original model data needed is then not available.

Also specify a **Relative tolerance** for the internal solver. The default value is decided when creating the model.

INFORMATION

This section contains information about the reduced model: Which study it is located in, which solution data that contains the reduced model data, the reduced model type, the analysis type, and some general information about the model reduction.

Under **Matrices**, all matrices that the reduced model solution includes are listed. The contents depend on if the reduced model is in the time domain or in the frequency domain. The list typically includes these matrices (among others):

- Stiffness matrix
- Damping matrix
- Mass matrix
- Input matrix
- Output matrix

Under **Vectors**, all vectors that the reduced model solution includes are listed. The contents depend on if the reduced model is in the time domain or in the frequency domain. The list typically includes these vectors (among others):

- Load vector
- Initial value vector

BUILD LOG

The build log contains output from the reduced-order model solution process, such as time steps with the step sizes, error estimates, and other information, similar to other solver logs.

6

Visualization and Selection Tools

COMSOL Multiphysics® provides a number of tools to visualize and control how you view models and select parts of the model geometry in the Graphics window and the Settings windows.

In this chapter:

- [Working with Geometric Entities](#)
- [Creating Named Selections](#)
- [User-Defined Views](#)

Working with Geometric Entities

The topics in this section provide you with an introduction to the following:

- [About Geometric Entities](#) defines the types of geometric entities in COMSOL, including information about adjacent and overlapping objects in the Graphics window.
- [The Graphics Window](#) is the environment where the geometry is visualized and selected.
- [About Selecting Geometric Entities](#) is an important section that helps you to understand how to highlight, select, or hide any part of the geometry using buttons, mouse clicks, keyboard shortcuts, or combinations of actions. Many physics feature node Settings windows have a common selection section, [The Geometry Entity Selection Sections](#), which also has several useful buttons available on the [Settings Window Toolbar](#).
- [The Selection List Window](#) is a tool to help you to list all the specific geometric entities in the model and to locate and select, for example, small parts of complex geometries.
- [About Highlighted Geometric Entities in the Graphics Window](#) describes the color scheme used to help you visually determine what geometric entities are included or excluded in a model. This makes it easy to add or remove domains, boundaries, edges, or points to the model. Also see
- The section [Selecting and Clearing Selection of Geometric Entities](#) has a table with a list of the different ways to select geometry using a variety of windows, mouse buttons, clicks, and keyboard shortcuts.
- The [Graphics Window Toolbar Buttons and Navigation](#) section includes a table with the different icons that display in the Model Builder (based on space dimension). The rest of the section describes the tasks related to the toolbar: [Zooming In and Out in the Graphics Window](#), [Changing Views in the Graphics Window](#), [Moving Around and Rotating a 3D Geometry](#), [Lighting](#), [Transparency](#), [Projection](#), and [Wireframe Rendering](#), and [Hiding and Showing Geometric Entities](#).
- The section [Using A 3D Mouse from 3Dconnexion](#) describes how to activate and use a SpaceMouse® from 3Dconnexion®.

About Geometric Entities

Conceptually, a geometry is a collection of bounded *geometric entities*. Those entities are volumes, surfaces, curves, or points. Geometric entities include *domains*, *boundaries*, *edges* (3D only), and *points*. For example, a 3D cube consists of one domain with six boundaries. The six boundaries have 12 edges and the edges connect at eight points (see [Figure 6-1](#)). This enables visualization of a cube by displaying one or more of these four types. For instance, you can create a wireframe plot by rendering only the cube's edges.

Geometric entities of the maximum dimension are called *domains*, while those of the next highest dimension are called *boundaries*. The boundaries are sometimes referred to as *faces* in 3D and *edges* in 2D. The *vertices* are also called *points*.

[Table 6-1](#) summarizes the terms used in COMSOL Multiphysics.

TABLE 6-1: NAMES OF GEOMETRIC ENTITIES IN DIFFERENT SPACE DIMENSIONS

ENTITY DIMENSION	NAME IN 3D	NAME IN 2D	NAME IN 1D	NAME IN 0D
3D	domain			
2D	boundary	domain		
1D	edge	boundary	domain	
0D	vertex	vertex	boundary	domain

These rules apply to domains:

- The (interiors of the) domains are disjointed. However, this is only strictly true if the finalization method is to form a union. When it is to form an assembly, domains can overlap (though that is normally considered a modeling error).
- Every geometric entity is bounded by entities of smaller dimension. In particular, a domain (in 3D, 2D, or 1D) is bounded by boundaries, edges (in 3D), and vertices (in 3D and 2D). A boundary (in 3D or 2D) is bounded by edges (in 3D) and vertices. An edge is bounded by vertices.

ADJACENT, OVERLAPPING, AND HIDDEN GEOMETRIC ENTITIES

Geometric entities are *adjacent* if they connect directly to each other within a geometry object. Hence all boundaries, edges, and points on the cube are adjacent to the domain. An edge on the cube is adjacent to two boundaries and two points.

When you click a 3D geometry that consists of several objects, geometric entities of the same type might overlap and hide each other at the point where you click. *Overlapping* geometric entities, such as interior boundaries, are highlighted and selected starting with the closest geometric entity and ending with the entity the farthest away. Use the scroll wheel (mouse wheel) to move the highlighting from the closest overlapping entity forward and back by rolling the wheel forward and backward (if you use COMSOL Multiphysics on a computer with a touchpad instead of a mouse, use its equivalent to the wheel; for example, moving two adjoining fingers up or down the touchpad). Then click to select the highlighted entity. If you can move the mouse wheel in small distinct increments, each such increment moves the selection to the next or previous entity that you can reach. Alternatively, use the plus key (+) and minus key (-) to highlight the next or previous entity, respectively.

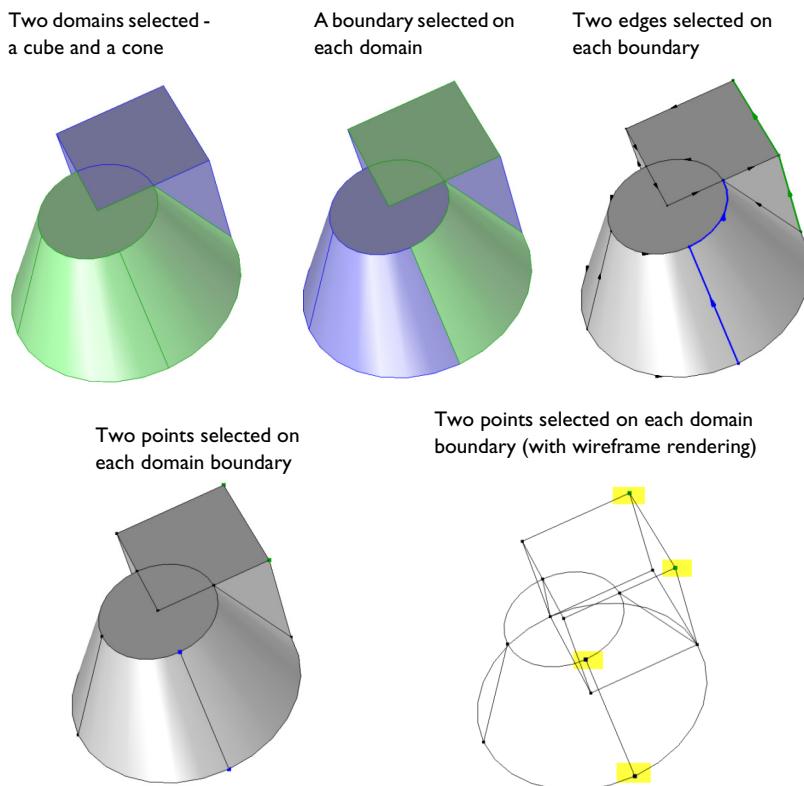

Figure 6-1: A 3D geometry comprises domains, boundaries, edges, and points.

- [The Graphics Window](#)
- [About Selecting Geometric Entities](#)
- [About Highlighted Geometric Entities in the Graphics Window](#)

The Graphics Window

The **Graphics** window (Figure 6-2) is a graphical view of the geometry, mesh, and results of the model. The window has useful tools for changing the view and selecting multiple entities — geometry objects when creating the geometry as well as domains, boundaries, edges, and points to define the physics features or to select geometric entities for fine-tuning the mesh or evaluating quantities in a certain part of the model, for example.

The toolbar at the top of the Graphics window has a set of tools for changing the visualization (for example, to zoom in or out or to add transparency) and for making selections. The available tools are dynamic and change based on the space dimension and what you are viewing in the graphics window at the time.

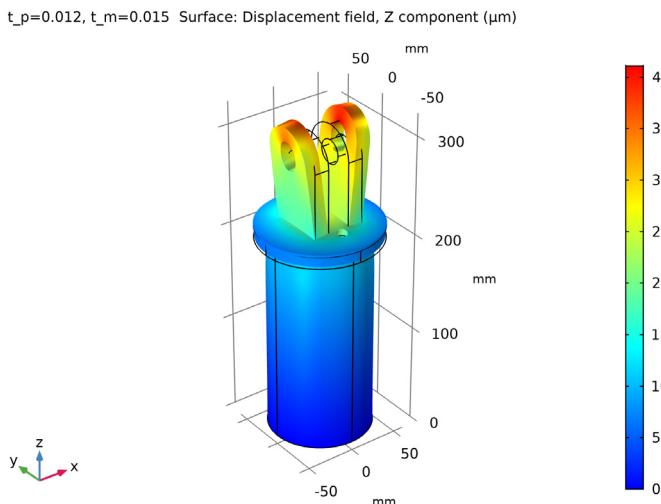

Figure 6-2: The Graphics window displaying a Surface plot for the Diagonal Mounting Detail of a Communication Mast model. This image displays for Windows users. The macOS and Linux Graphics window looks slightly different but functions the same and has the same toolbar.

ABOUT GRAPHICS RENDERING

For the graphics rendering, COMSOL uses OpenGL® rendering by default. It is also possible to use DirectX® rendering (Windows® only) or software rendering. Software rendering may be necessary in some cases, such as running COMSOL via a remote connection. You can change the type of rendering from the **Rendering** list on the **Graphics and Plot Windows** page in the **Preferences** dialog box.

- [Capturing and Copying Screenshots](#)
- [About Geometric Entities](#)
- [The Graphics Window Toolbar Buttons and Navigation](#)
- [Creating Named Selections](#)
- [Physics Symbols](#)

Basic Selection Concepts

The following basic selection concepts are useful for picking geometric entities where you want to apply physics, boundary conditions, or other parts of the model:

- To pick a geometric entity in the **Graphics** window and add it to the current node's selection list, simply click it. The geometric entity then appears in the selection list. Click again to deselect.
- You can also use the **Selection List** window to pick geometric entities, which you then add to the current selection by right-clicking and selecting **Add to Selection** or clicking the corresponding toolbar button (). You can select multiple entities from the selection lists using Ctrl-click or Shift-click.
- It is good practice to add selection nodes with a selection of geometric entities that you can give a descriptive name and that contains geometric entities that represent a specific part of the geometry (a ground plane or an outlet, for example). You can then choose that selection node as a predefined selection from the **Selection** lists in the physics nodes, for example.
- For adding physics nodes from the toolbars, it can be useful to use a *preselection* by setting the Active button to off in the current **Settings** window. You can then select geometric entities and click the toolbar button for the physics nodes that you want to add. That physics node, when added, then gets the selection that you have preselected.

About Highlighted Geometric Entities in the Graphics Window

The Graphics window in the COMSOL Desktop highlights geometric entities at different stages of selection. A geometric entity is highlighted in red, blue, green, yellow, or with no highlight (gray) to indicate its status.

	Another visual cue to help you work in the Graphics window is that the geometry can have thicker edges (with OpenGL and Software rendering only, not DirectX), or larger points to highlight the different geometric entities selected. With the default graphics preference, to optimize for quality (for graphics cards that support it), highlighted geometric entities appear with a “glowing edge”. If required, change the default from The Preferences Dialog Box under Graphics and Plot Windows>Visualization .
---	--

When assigning geometric entities to a node and you hover over that entity in the Graphics window, click once to add it to a selection list. See [Figure 6-5](#) for an example. If you select the **Require click in Graphics window to activate hovering** check box under **Selections** on the **Graphics and Plot Windows** page in the **Preferences** dialog box, then you must first click once in the Graphics window before you can hover and click to select. See also [Selection Colors](#) below.

BLUE

For geometric entities added to a selection. A geometric entity highlighted in blue is included in the list of selected entities for the specific node. See [Figure 6-4](#) for an example.

RED

Hovering over or selecting unselected geometric entities. When you hover over a geometric entity that has not yet been added to a selection, or if you select such a geometric entity in [The Selection List Window](#), it is highlighted in red to help you locate it on the Graphics window. See [Figure 6-4](#) and [Figure 6-5](#) for examples.

	An entity highlighted in red is not yet added as a selection. Either click it in the Graphics window, or right-click the entity in the list or click the Add to Selection button in the Selection List window. The entity is then highlighted in blue to indicated that it has been added to the selection.
---	--

GREEN

Hovering over or selecting selected geometric entities. When you hover over a geometric entity that has already been added to a selection, or if you select such a geometric entity in the **Selection List** window (indicated by **(selected)** next to the entity number), it displays in green to indicate that it is included in the selection list. See [Figure 6-4](#) for an example.

GRAY (NO HIGHLIGHT)

If the geometric entity is gray (that is, not highlighted), it means it is not selected or included for that node and geometric entity level. See [Figure 6-5](#) for an example.

YELLOW

Next to the **Settings** window's selection list, there is an **Active** button to toggle between turning ON  and OFF  selections; that is, making the selections active for that selection list.

When the button is toggled to OFF, the selection mode is a *preselection* that is used for a selection that you add to the model from the toolbar, and the selection for the current node in the model tree is highlighted in yellow in the **Graphics** window. See [Figure 6-3](#).

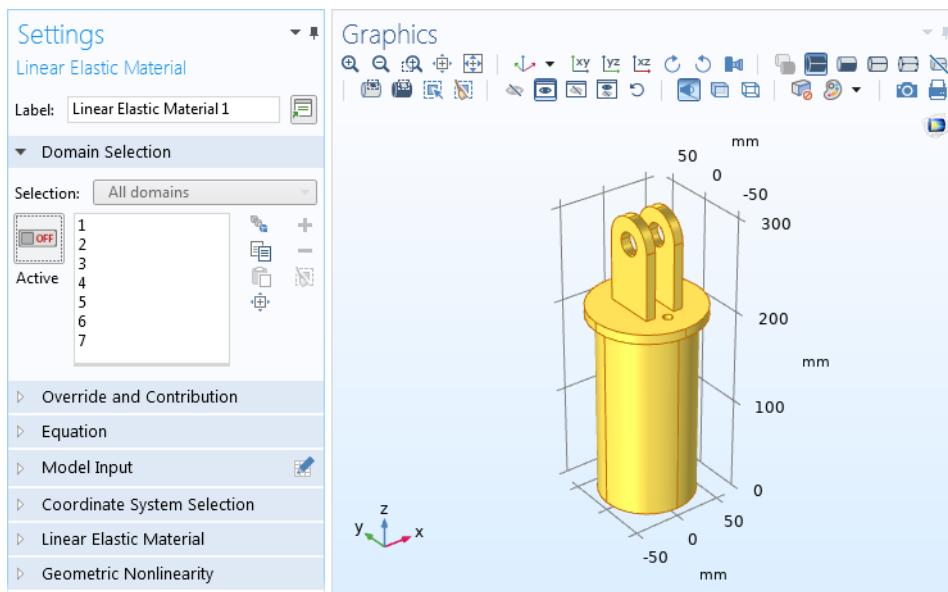

Figure 6-3: When the Active button is OFF, the selection for the current node is highlighted in yellow.

Hover over an entity in the Graphics window. When the selection is active, add or subtract it from the selection list (see [Figure 6-6](#)) by observing how the colors cycle on and off:

COLOR WHEN HOVERED OVER	CURRENT STATUS	NEW COLOR WHEN CLICKED	NEW STATUS WHEN CLICKED
Green	Included as a selection for the node.	Gray	Not included as a selection for the node.
Red	Not included as a selection for the node.	Blue	Included as a selection for the node.

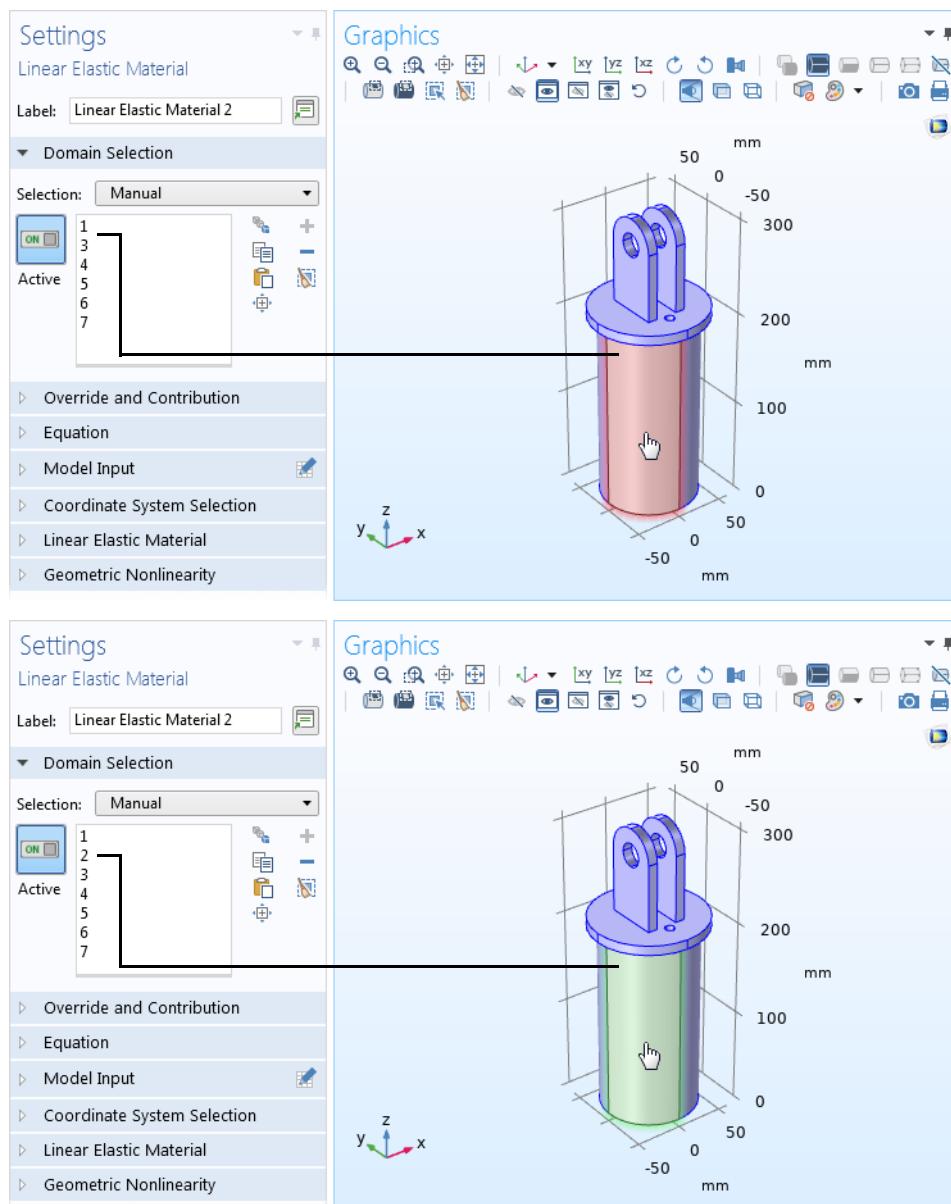

Figure 6-4: Domain 2 is removed from the Selection on the Settings window for Linear Elastic Material. When you hover over it, it is highlighted in red in the Graphics window to indicate where it is on the geometry (top image). Click to add Domain 2 back to the selection, and Hover over a geometric entity in the Graphics window and it displays in green (bottom image). This example uses the Diagonal Mounting Detail of a Communication Mast model.

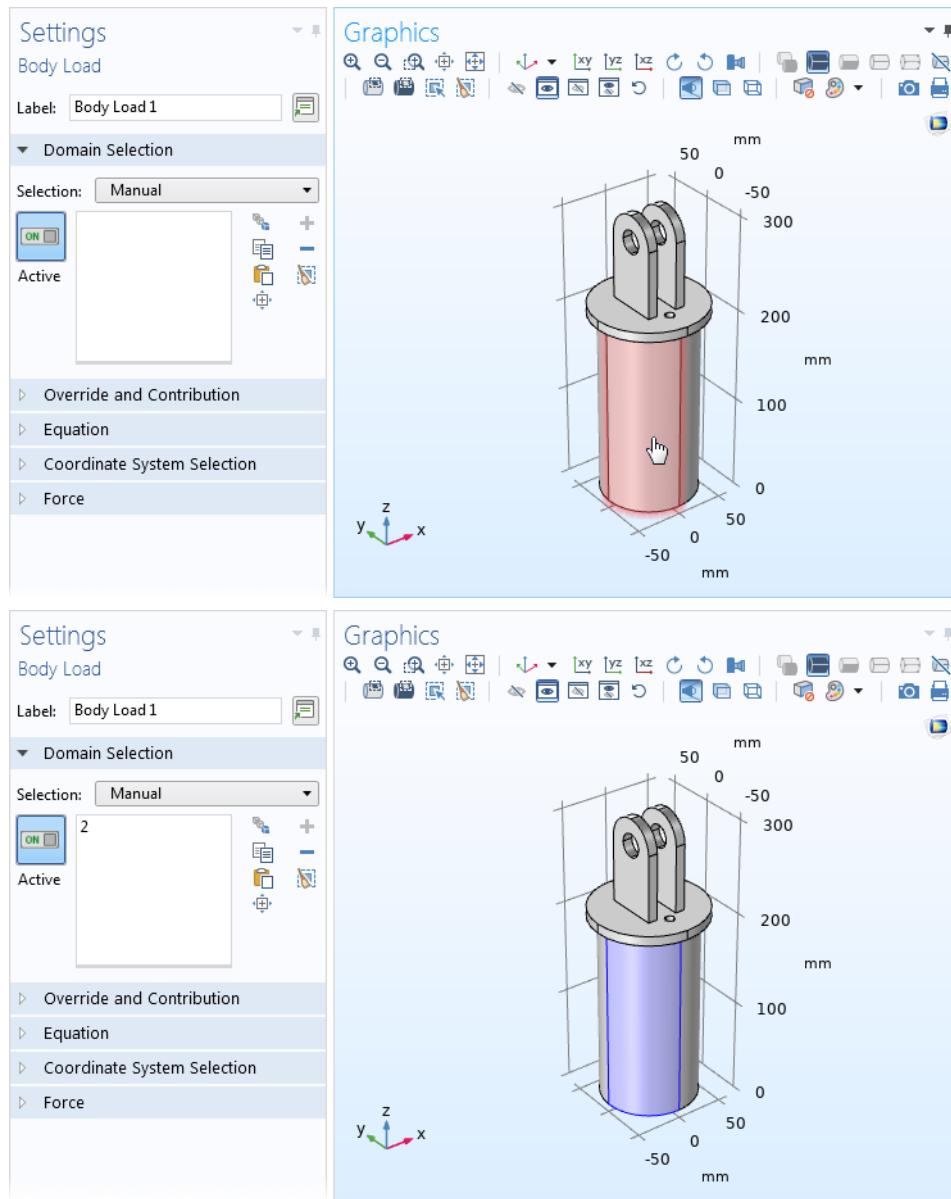

Figure 6-5: You want to add a domain to the Body Load node to make the load act on that domain. When you hover over a geometric entity in the Graphics window it displays in red to indicate it has not been added to the selection list (top). Click the domain to add it to the selection list on the Settings window and it displays in blue to indicate it has successfully been added (bottom). In both images, gray-colored domains are not selected or included.

Selection Colors

USING SELECTION COLORS

Using selection colors in 2D and 3D models can make it easier to distinguish between selections of geometry objects and geometric entities. You can add a selection color to all selection nodes that you add from the **Selections** menu when right-clicking a **Definitions** node (or from the **Definitions** toolbar). In their **Settings** window, you can choose a color that represents that selection from the **Color** list. You can also assign colors using a **Color** list when you select the **Resulting objects selection** in the **Settings** window for most geometric primitives and geometry operations in geometry sequences.

From the color palette that opens you can choose **None** (the default, for no color); choose a color from the list of theme colors; or define and add custom colors that you can choose from by clicking **Define custom colors**, define a new custom color, and then click **Add to custom colors**. You specify a color theme in the **Preferences** dialog box on the **Graphics and Plot Windows** page. You can also specify it in the root node's **Settings** window. The color themes contains a set of colors that are chosen to form a suitable theme.

When you change the color theme, the colors chosen from the previous color theme change to the colors for the new color theme at the same positions in the list of theme colors.

COLOR APPEARANCE AND PRECEDENCE

Colors defined in the geometry sequence are displayed when viewing the geometry sequence. They are also displayed for the finalized geometry (for example, when working with the mesh and physics) but only if that selection has the **Show in physics** option selected. Colors for selections and materials are not displayed in the geometry sequence.

The selection colors, the colors for selection highlighting, and colors for materials cannot appear at the same time. The following precedence rules control which color to display:

- Selection-related colors always have precedence.
- Selection-feature colors have precedence over geometry colors.
- If multiple selection features define a color for the same entity, the precedence order is as follows:
 - a Boundary color
 - b Domain color
 - c Object color
- If several selections define a color for the same entity, latter features in the list override former.
- Material colors have precedence over selection-feature colors (but material colors are not enabled by default).

By clicking the **SUPPRESS SELECTION HIGHLIGHT** button () you can temporarily disable the selection highlight colors in the Graphics window. The state is reset automatically when you, for example, switch node in the **Model Builder**.

CONTROLLING THE SELECTION COLORS

From the **Colors** menus () on the Definitions and Geometry toolbar you can choose the following actions for selection colors in definitions nodes and in geometry nodes, respectively:

- Choose **Color Selections** () to color all selections using colors from the current color theme.
- Choose **Reset Colors from Theme** () to reset all colors to those from the current color theme.
- Choose **Remove Selection Colors** () to remove all selection colors so that they are set to **None**.

These settings are also available in a **Group** node that you have created and that contains a number of selection nodes, for example.

On the **Graphics** window toolbar, you can choose **Show Selection Colors** and **Show Material Colors and Texture** from the **Colors** menu () to control the display of selection colors and material color and texture. Both of them can be selected at the same time. The same settings are also available in the **Colors** section of the **View** nodes' **Settings** window.

About Selecting Geometric Entities

Throughout COMSOL Multiphysics there are many lists of selected geometric entities, all based on the same principle — pick domains, boundaries, edges, or points and use methods to add or remove these geometric entities

to create *selections* that define, for example, the parts of the geometry where a material or boundary condition is active. Such lists appear in **Settings** windows for defining equations and material properties, boundary conditions, sources, and other parts of the model's design, or the **Variables** node (**a=**) definitions for variables that are not defined in the entire model.

All levels of geometry can be treated individually. You can add and remove 3D geometric entities (domains, boundaries, edges, or points) to selection lists in different ways, including buttons in the **Graphics** toolbar (The **Graphics Window Toolbar Buttons and Navigation**), using **The Selection List Window**, clicking directly on the geometry, or clicking buttons in the **Settings** window. You can also select entities in the list to then remove them from the selection, for example. **Ctrl+A** selects all entities in the list. **Table 6-2** lists the buttons that display on every **Settings** window with a geometric entity selection list as displayed in **Figure 6-6**.

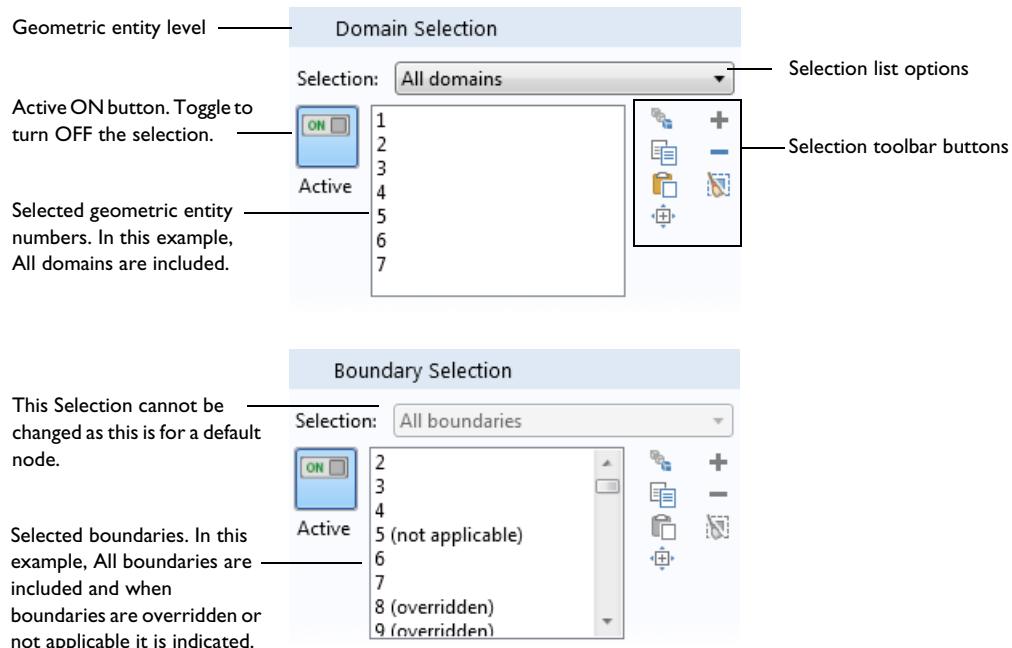

Figure 6-6: The selection list and toolbar on a physics node Settings window. The geometric entity level for the top Settings window is domains. The bottom Settings window is for a default boundary condition node where the selection cannot be changed, although a boundary can be overridden.

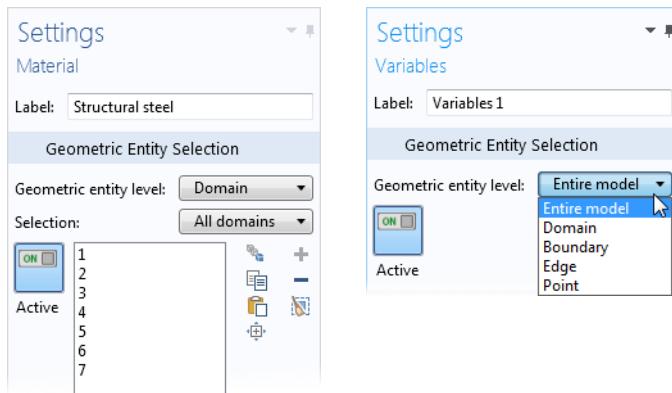

Figure 6-7: The Geometric entity level selection list and toolbar on a Settings window for Material (left) and the Settings window for Variables (right).

In [The Graphics Window](#), the geometric entities are color highlighted as you make the selections, and you can lock the selections by turning off the active selection (at most one selection can be active at a time) or click the **Select Node** button (in 3D) in the **Graphics** window toolbar.

THE GEOMETRY ENTITY SELECTION SECTIONS

The name of the section where the list of selected geometric entities is managed depends on the geometric entity level. For example, [Figure 6-6](#) displays a **Domain Selection** section.

Every geometric entity selection section also has an **Active** button to toggle between turning ON and OFF selections for that node.

For physics nodes that are default nodes (see [Physics Interface Default Nodes](#)) the selection defaults to all geometric entities on the applicable level (all domains or all boundaries, for example, in [Figure 6-6](#)), and the **Selection** list is not active. You can add other nodes that override the default nodes for some or all entities. Those entities are then marked **(overridden)** in the selection list for the default node.

- **Geometric Entity Selection:** For **Materials** and **Variables** nodes, where you first select the level (domain, boundary, and so on), from a **Geometric entity level** list. See [Figure 6-7](#) for an example using the “Diagonal Mounting Detail of a Communication Mast” model.
- **Domain Selection:** For nodes that define, for example, material models, sources, and body loads in domains. See [Figure 6-6](#) for an example.
- **Boundary Selection:** For nodes that define, for example, boundary conditions.
- **Edge Selection:** For nodes that define, for example, conditions and forces on edges. This is applicable to 3D models only.
- **Point Selection:** For nodes that define, for example, point sources and point loads.

From the **Selection** list you can choose one of the following options:

- **Manual** (the default): Select the geometric entities directly in the **Graphics** window, using [The Selection List Window](#), or using the **Paste Selection** button. See below for more information about those selection methods.

If you start by setting the **Geometric entity level** to **Domain**, and then select **All domains**, the **Selection** list displays all domains. If you make any changes to this list (for example, remove a domain) the **Selection** list reverts to **Manual**.

- **All domains, All boundaries, All edges, All points:** Depending on the geometric entity level, you can choose one of these options to select all entities. See [Figure 6-6](#) for example.
- Defined named selections: Selection nodes added in the geometry sequence or under **Definitions** (as well as selections created from Boolean operations, for example) are available in the **Selection** lists for nodes that define model properties for the same geometric entity level. You can rename such selection nodes to better reflect what the selected entities represent. A named selection can consist of, for example, the domains where a volume force acts, the boundaries where an inflow occurs, or points that are grounded. Named selections are useful for reusing selections in a model component and to clearly indicate what parts of geometry that the selected entities include or represent. See [Creating Named Selections](#).

In the lists of selected entities, **(overridden)** and **(not applicable)** can display next to the label (the number) of a selected entity. See [Figure 6-6](#) and [Physics Node Status](#) for more information about these status indicators. There is also an **Override and Contribution** section in all physics nodes. It provides an overview of how the physics nodes and their selections interact. See [Physics Exclusive and Contributing Node Types](#).

Pair Selection

If the geometry is an assembly you have access to specific pair conditions (typically on boundaries) that you choose from a **Pairs** submenu on the main physics nodes' context menus. In the **Settings** window for such pair nodes, a **Pair Selection** section contains a list of the applicable pairs (typically identity pairs). The **Boundary Selection** section (or another standard selection section) is then not possible to modify and shows the entity numbers for the boundaries, for example, that the selected pairs include. Select one or more pairs from the **Pairs** list to specify where to apply the pair condition. See [Identity and Contact Pairs](#).

See [Table 6-3](#) for the many ways to select geometric entities using toolbar buttons, mouse click options, page settings, and keyboard shortcuts.

SETTINGS WINDOW TOOLBAR

TABLE 6-2: GEOMETRIC ENTITY SELECTION BUTTONS ON VARIOUS SETTINGS WINDOWS

BUTTON	NAME	DESCRIPTION
	Active ON	Click the Active button ON to make the selection of geometric entities to the Selection list active for that particular node.
	Active OFF	Click the Active button OFF to lock/deactivate the geometric entities in the Selection list for that particular node. The selected entities in the geometry are highlighted in yellow in the Graphics window. See Figure 6-3 for an example. The Graphics window is then available for preselection of entities for a new node.
	Create Selection	Use this button to create selection nodes under Definitions to represent various parts of the geometry and simplify the process of assigning materials, model equations, boundary conditions, and model properties. See Creating Named Selections . This button is also on The Selection List Window .
	Copy Selection	Use this button to copy the selection from the list in the Settings window to the clipboard. See Copying and Pasting Selection Lists . This button is also on The Selection List Window (except when in the Geometry mode).
	Paste Selection	Use this button if you have a list of geometry objects or geometric entities in a file or document, or that you have copied using Copy Selection, that you want to type in and then paste into a selection list. If you copy a selection from a document to the clipboard, you can paste the selection using Ctrl+V. An example is a list of geometric entity numbers described as a step in a modeling instruction. See Copying and Pasting Selection Lists . This button is also on The Selection List Window (except when in the Geometry mode).

TABLE 6-2: GEOMETRIC ENTITY SELECTION BUTTONS ON VARIOUS SETTINGS WINDOWS

BUTTON	NAME	DESCRIPTION
	Add to Selection	Use this button to add a geometric entity to a selection list. See Table 6-3 . This button is also on The Selection List Window .
	Remove from Selection	Use this button to remove a geometric entity from the Selection list. See Table 6-3 . This button is also on The Selection List Window .
	Clear Selection	Use this button to clear a selection. Clearing the selection also activates the selection for that node.
	Zoom to Selection	Use this button to zoom into the selected geometric entities. This zoom operation also updates the center of rotation and sets a manual rotation center, which will stay active until you click the Zoom Extents or the Go to Default 3D View button to reset it or switch to an automatic rotation center in some other way.

The Selection List Window

Use the **Selection List** window ()(see [Figure 6-8](#)) to make it easier to choose objects, for example, while working with complex geometries and when you need to easily locate a geometric entity that is not easily viewed. The Selection List is particularly useful when you know the geometric entity number to select; for example, when you are following step-by-step instructions to build an example from the application libraries (in that case, you can also copy and paste the selections directly from the instructions).

	To open the window, from the Home toolbar select Windows>Selection List (.
	To open the window, select Windows>Selection List (.

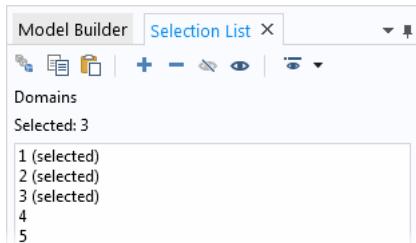

Figure 6-8: The Selection List window and toolbar. Most of the toolbar buttons are also on a node Settings windows. In this example, the numerical representation for the domains is listed. See [Table 6-2](#) for button information.

WORKING WITH THE SELECTION LIST WINDOW

The **Selection List** window displays all geometric entities of a certain type (boundaries, for example). COMSOL Multiphysics determines the geometric entities listed based on where in the model you are working. This is different from selection lists in **Settings** windows, which contain lists of the selected entities only (see [About Selecting Geometric Entities](#), [Figure 6-6](#)). At the top of the window, the **Selection List** window displays the number of selected entities.

Click the **Create Selection** button () and enter a **Selection name** in the **Create Selection** window to create a new **Explicit** selection. See [Copying and Pasting Selection Lists](#) for information about the **Copy** and **Paste** buttons.

Use the **Add to Selection** button () to add a selected entity from the **Selection List** window to a selection for boundary condition, for example. Use the **Remove from Selection** button () to remove selected items from a selection. Use the **Hide** () and **Show** () buttons to hide and show selected geometric entities, respectively. You can also right-click an item in the selection list and choose any of those four menu options (**Add to Selection**, **Remove from Selection**, **Hide**, or **Show**).

Selecting from and Filtering the Selection List

The selected items in the **Selection List** window are indicated by **(selected)** next to the entity label, except if you choose to only list the selected items by selecting **Only List Selected** from the **Filter List** menu () on the **Selection List** toolbar.

Click any item to see it highlighted in [The Graphics Window](#) — except if the item is hidden, which is indicated in the Selection List by **(hidden)**, unless you choose to only list the visible items by selecting **Only List Visible** from the **Filter List** menu () on the **Selection List** toolbar — and select items as described in [Selecting and Clearing Selection of Geometric Entities](#).

From the **Filter List** menu () on the **Selection List** toolbar, you can filter the list of selected entities by choosing **Only List Selected**, **Only List Visible**, and **Only List Applicable** as desired. Choose to **Only List Applicable** if the model includes many entities that are selected but not applicable, for example.

Using the Selection List

For example, you can use the Selection List in the following situations.

Materials, Physics, and Boundary Conditions: When working in windows with Selection or Geometric scope sections (a **Selection** window under a **Definitions** node for example), or anywhere you assign materials, physics features, boundary conditions, and other Component settings. The Selection List displays the specific *geometric entity level* selected (domain, boundary, edge, or point).

Geometry: When in the Model Builder under the **Geometry** node, the geometry objects are displayed in the **Entities to select**, for example, **ext1** (extrusion), **b1k1** (solid), or **cone1** (solid) ([Figure 6-9](#)). You might also use it with a **Chamfer** or **Fillet** geometry feature when you want to locate specific points. To specify the selection level, click the **Select Points** button in the **Graphics** window toolbar and add the points to the **Vertices to fillet** or **Vertices to chamfer** lists. See [Creating Named Selections in the Geometry Sequence](#) for details about creating selections based on geometry sequences.

Meshing: When in the Model Builder under the **Mesh** node, the list also includes information on which entities are meshed by adding **(meshed)** to the right of the meshed entities. If the Geometry has Mesh Construction entities, the list also specifies if a construction entity has been removed; see [Mesh Control Entities](#). This is indicated next to the entity in the list by **(meshed and removed)**.

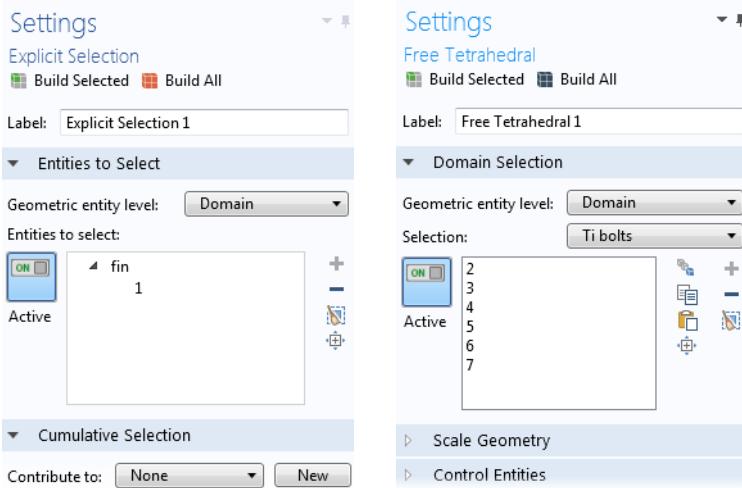

Figure 6-9: An example of a Settings window for Explicit Selection for a Geometry sequence (left) and a Free Settings window for Tetrahedral for a Mesh node (right).

- [Creating Named Selections](#)
- [About Selecting Geometric Entities](#)

Selecting and Clearing Selection of Geometric Entities

The sections [About Selecting Geometric Entities](#) and [The Selection List Window](#) give an overview of some of the tools and windows available to highlight and select geometric entities. [About Highlighted Geometric Entities in the Graphics Window](#) describes the different colors that display in the Graphics window to help you select geometric entities to include in your model.

Table 6-3 contains the description of the different ways to complete the same task of selecting (or deselecting) geometric entities.

TABLE 6-3: DIFFERENT WAYS TO SELECT GEOMETRIC ENTITIES

TASK	ACTION
Select any level of geometry:	In The Graphics Window , click the geometric entity to add it to an active selection list in the current node's Settings window. Open The Selection List Window and click entity numbers (or names); then click the Add to Selection button (+) to add it to an active selection list in the current node's Settings window. You can also add an entity to an active selection list in the current node's Settings window by double-clicking it or by right-clicking it and selecting Add to Selection .
Select all parts of the geometry:	In most Settings windows' selection sections, the option to select All domains , All boundaries , All edges , or All points adds all geometric entities of that type to the list of selected entities. The selected items are highlighted in the Graphics window and all entities are kept selected, even if the geometry changes. Open The Selection List Window and use the Shift or Ctrl keys to select all of the entity names (or numbers). You can also click the main geometry node to select all entities that the node includes. Then click the Add to Selection button (+) to add it to an active selection list in the current node's Settings window. In the Graphics window, click the Select All button (A in 3D), or click outside of the geometry or press Ctrl+A to select all entities. For Windows users, a Select All button is available on a customized Quick Access Toolbar. For macOS and Linux users, from the main menu select Edit>Select All . This highlights and selects all entities but does not confirm the selection or lock it if the model changes.
Clear the selection of all parts of the geometry not added to a selection list:	In the Graphics window, click the Clear Selection button (C), or click outside of the geometry or press Ctrl+D to clear all selected entities. For Windows users, a Clear Selection button is available on a customized Quick Access Toolbar. For macOS and Linux users, from the main menu select Edit>Clear Selection .
Move, rotate, and then select (3D only):	Multiple mouse actions can be done together. For example, use the mouse to rotate or move the object left and right to locate the geometric entity to add to a selection list; then click to add to the selection.
Lock the geometry selection settings during selection:	In the Graphics window, click the Select None button (N). Then no clicks in the graphics highlight or select any geometric entities, which makes it possible to move and rotate the geometry freely.
Add to Selection + :	In the Graphics window, click a red highlighted entity to add it and make it blue. Or select one or more geometric entities and click the Add to Selection button. In the Selection List window, select the entity names to add, and click the Add to Selection button. You can also paste selections from a file. See Copying and Pasting Selection Lists for information. For user-defined selections this action must be completed on the selection page. See Create an Explicit Selection from the Selection List Window for information.
Select Box: 	To select multiple parts of the geometry, in the Graphics window, click the Select Box button; then click and hold the left mouse button to draw a square over the geometry. It is like a "rubberband," selecting all entities enclosed by this operation. The selected geometric entities are added to the selection list. In the Selection List window, use the Shift or Ctrl keys to select the entity names (or numbers). Click the Add to Selection button.

TABLE 6-3: DIFFERENT WAYS TO SELECT GEOMETRIC ENTITIES

TASK	ACTION
Deselect Box: 	To deselect multiple parts of the geometry, in the Graphics window, click the Deselect Box button; then click and hold the left mouse button to draw a square over the geometry. It is like a “rubberband,” deselecting all entities enclosed by this operation. The deselected geometric entities are removed from the selection list. In the Selection List window, use the Shift or Ctrl keys to select the entity names (or numbers). Click the Remove from Selection button.
Select Objects: 	In the Graphics window, click the Select Objects button. Click to select the geometry object and add it to the selection list.
Select Domains: 	In the Graphics window, click the Select Domains button. Click to select the domains and add it to the selection list. In the Settings window, select Domain from a Geometry entity level list and then click in the Graphics window. Only domains are highlighted.
Select Boundaries: 	In the Graphics window, click the Select Boundaries button. Click to select the boundary and add it to the selection list. In the Settings window, select Boundary from a geometry entity level selection list and then click in the Graphics window. Only boundaries are highlighted.
Select Edges 	In the Graphics window, click the Select Edges button. Click to select the edge and add it to the selection list. In the Settings window, select Edge from a geometry entity level selection list and then click in the Graphics window. Only edges are highlighted.
Select Points: 	In the Graphics window, click the Select Points button. Click to select the point and add it to the selection list. In the Settings window, select Point from a geometry entity level selection list and then click in the Graphics window. Only points are highlighted.
Select None: 	In the Graphics window, click the Select None button to turn off all selections so that you can click in the Graphics window to move or rotate the geometry, for example, without adding any object or entity to a selection.
Select All 	In the Graphics window, click the Select All button to select all objects or entities.
Edit 	Interactive editing of 2D geometry objects so that you can click-and-drag to resize and move geometry objects. Alt-click a 2D geometry object to edit its underlying properties and drag its control points, for example. Right-click to edit that geometry editing mode. See Moving and Scaling 2D Objects in the Graphics Window .
Remove from Selection 	In the list, mark the geometric entity and click the Remove from Selection button. In the Graphics window, click to highlight and select the geometric entity to remove. Any blue geometric entity turns gray to indicate it is removed from the selection. In the Selection List window, use the Shift or Ctrl keys to select the entity names to remove. Click the Remove from Selection button. For user-defined selections this action must be completed on the selection page. See Create an Explicit Selection from the Selection List Window for information.
Clear Selection 	Click the Clear Selection button to clear all selections from the selection list. For user-defined selections this action must be completed on the selection page. See Create an Explicit Selection from the Selection List Window for information.

The Graphics Window Toolbar Buttons and Navigation

Some of the toolbar buttons available on the **Graphics** window are different based on the space dimension of the Component. The buttons also correspond to domain, boundary, edge, and point level nodes that display under the physics interface, which are also based on the Component space dimension as shown in [Table 6-4](#). The buttons in [Table 6-5](#) are available in any space dimension.

In the tables there are links to the corresponding sections that contain instructions about how to do the listed tasks.

	Print	Printing from the COMSOL Desktop

ZOOMING IN AND OUT IN THE GRAPHICS WINDOW

BUTTON	NAME	ACTION
	Zoom In and Zoom Out	Click the Zoom In button to zoom in. Click the Zoom Out button to zoom out. Click the middle mouse button and drag it forward and backward to zoom in and out of the object. The zoom is centered where the first click is made in the Graphics window.
	Zoom Box	To zoom into a general area of the geometry, click the Zoom Box button then click and drag to highlight a section of the geometry to zoom into.
	Zoom to Selection	Click the Zoom to Selection button to zoom into the selected geometric entities. This button is also available in connection with the selection lists for domains, boundaries, edges, and points. This zoom operation also updates the center of rotation and sets a manual rotation center, which will stay active until you click the Zoom Extents or the Go to Default 3D View button or otherwise change the mode of the rotation center.
	Zoom Extents	Click the Zoom Extents button to zoom out and fit the complete geometry into the window.
	Zoom to Point	Ctrl+middle-mouse click to zoom to the point that the mouse points to. This zoom action sets a manual rotation center and zooms into the point.

CHANGING VIEWS IN THE GRAPHICS WINDOW

BUTTON	NAME	ACTION
	Go to XY View, Go to YZ View, and Go to XZ View (3D only)	Click the Go to XY View , Go to YZ View , and Go to XZ View buttons to change the view to the xy-, yz-, or xz-plane in a 3D Graphics window. The first click selects the plane view with a positive normal direction. A second click on the same button switches to a negative normal direction. A third click flips the direction in the plane, and a fourth click switches the normal again, so the clicks cycle through all four possible views for the chosen plane.
	Go to Default View	Click the Go to Default View button to change the view to the default view in a 3D Graphics window.
	Display a user-defined view:	After creating a View under the Definitions node, click the down arrow next to the Go to View button () and select a user-defined view from the list.
	Rotate Right 90°, Rotate Left 90°	Click the Rotate Right 90° and Rotate Left 90° buttons to rotate a geometry in a 3D Graphics window by 90° in the right (clockwise) or left (counterclockwise) direction.
	Show Axis Orientation	Click the Show Axis Orientation button to toggle the display of the axis orientation indicator (triad) in the lower-left corner of the 3D Graphics window on or off.
	Show Grid	Click the Show Grid button to toggle the display the grid box on or off in the 2D and 3D Graphics window.
	Show Legends	Click the Show Legends button to toggle the display of the color legend and color scale on or off in 2D and 3D Graphics windows or to toggle the display of legends on or off in 1D Graphics windows.

MOVING AROUND AND ROTATING A 3D GEOMETRY

There are many options available for moving around the **Graphics** window and rotating 3D geometries, in addition to the buttons for changing views listed under [Changing Views in the Graphics Window](#) above.

Controlling the Rotation

As the default, there is an automatic rotation center, so that the rotation center switches if there is something observable in the screen center. The automatic rotation center is good for navigating the model but not always for working on a local area of a big model. For that purpose, you can switch to a manual rotation center. Click the middle mouse button to set a new rotation center if you want to temporarily fix the rotation center (a manual rotation center). Zooming to a point or a selection also sets a manual rotation center. If you middle-click

somewhere in the **Graphics** window where there is no object, the rotation center switches back to the automatic mode. The manual rotation center is only temporary and is reset to the automatic mode if you click the **Zoom Extents**, **Go to Default View**, **Go to XY View**, **Go to YZ View**, or **Go to XZ View** button. You can switch between automatic and manual modes by pressing the R key, and the rotation center icon will appear to indicate the current mode, if it is activated. See the preferences settings below for disabling the automatic rotation center and the middle-mouse clicking and controlling the visibility of the rotation center icon, if desired.

If you want to permanently lock the current rotation center (in rare case you may need to do so; perhaps for creating snapshot images for a report), select the **Lock rotation center** check box in the **View** node's **Settings** window. It locks the rotation center permanently, so you have to clear this check box to unlock it. The current locked rotation center will be saved in the model.

The automatic, manual, and locked modes have different rotation center icons on the screen when you rotate the object or perform any mouse operation:

- For the automatic mode: 
- For the manual mode: 
- For the locked mode: 

The rotation center icon can be visible or hidden. You can specify the visibility in the **Preferences** dialog box, on the **Graphics and Plot Windows** page, as well as controlling if the automatic rotation center and the middle-click for specifying the rotation center should be active. Under **Rotation center**, the following settings are available:

- Clear the **Auto** check box to turn off the automatic rotation center (which is active by default).
- Clear the **Set with mouse middle-click** check box to turn off the automatic rotation center (which is active by default).
- From the **Visibility** list, choose **Always hide** (the default) to never show the rotation center icon, **Shown only on mouse action** to show it only when you click the mouse or press R to change the rotation center, or **Always show** to make it visible always.

Setting the manual rotation point in the **Graphics** windows is only supported for the OpenGL renderer.

Constrained Rotation

To rotate around the x -, y -, and z -axis, use the X, Y, and Z keyboard shortcuts. If you press and hold the X key when rotating a 3D geometry, it will rotate around the x -axis only (lock the x -axis). In the same way, press and hold the Y and Z keys to rotate around the corresponding axis. You can switch the rotation while rotating with the left mouse button active; for example, press and hold the X key and then release it; then press and hold the Y key to switch between locking the x -axis and the y -axis without releasing the left mouse button.

ADDITIONAL TOOLS FOR MOVING, ZOOMING, AND ROTATING

In addition, the following list contains additional tools that are available for moving, zooming, and rotating geometries in the Graphics window. Except where stated, these tools are available for 3D geometries only.

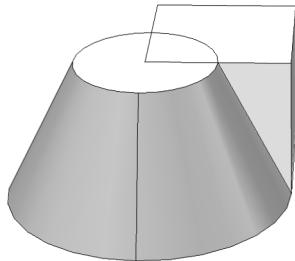

TASK	ACTION AND RESULT	OPERATION ORDER
Rotate the geometry about the axes	<p>In the Graphics window, left-click and hold down the mouse button while dragging it in any direction.</p> <p>This rotates the scene around the axes parallel to the screen X- and Y-axes with origin in the scene rotation point.</p>	left-click
Move the visible frame on the image plane in any direction (pan)	<p>In the Graphics window, right-click and hold down the mouse button while dragging it in any direction. Available in all space dimensions.</p>	right-click
Zoom in and out around the mouse position where the action started	<p>In the Graphics window, click and hold down the middle mouse button and drag the mouse forward or back to zoom in and out. Available in all space dimensions.</p>	middle-click
Set the manual rotation center	<p>In the Graphics window, click the middle mouse button.</p>	middle-click
Rotate about the X- and Y-axes in the image plane (tilt and pan the camera)	<p>Press Ctrl and left-click in the Graphics window. While holding down the key and button, drag the mouse in any direction.</p> <p>This places the rotation coordinate system in the camera and rotates around the axes parallel to the screen X- and Y-axes.</p>	Ctrl+left-click
Move the camera in the plane parallel to the image plane	<p>Press Ctrl and right-click in the Graphics window. While holding down the key and button, drag the mouse in any direction.</p>	Ctrl+right-click
Rotate the camera about the axis	<p>Press Ctrl+Alt, then left-click in the Graphics window. While holding down the keys and button, drag the mouse in any direction. If you have not rotated the camera (using Ctrl+left-click), the effect is the same as when using Alt+left-click.</p>	Ctrl+Alt+left-click
Move the scene in the plane orthogonal to the axis between the camera and the scene rotation point	<p>Press Alt, then right-click the mouse in the Graphics window. While holding down the key and button, drag the mouse in any direction.</p>	Alt+right-click
Move the camera into and away from the object (dolly in/out)	<p>Press Ctrl and then click the middle mouse button. While holding down both the key and button, in the Graphics window, drag the mouse in any direction.</p>	Ctrl+middle-click, hold and drag
Zoom to the point that the cursor points to.	<p>Press Ctrl and then click the middle mouse button.</p>	Ctrl+middle-click
Rotate the camera about its axis between the camera and the scene rotation point (roll direction)	<p>Press Alt, then left-click in the Graphics window. While holding down the key and button, drag the mouse in any direction.</p>	Alt+left-click
Move the camera along the axis between the camera and the scene's rotation point	<p>Press Alt, then middle-click in the Graphics window. While holding down the key and button, drag the mouse in any direction.</p>	Alt+middle-click

LIGHTING, TRANSPARENCY, PROJECTION, AND WIREFRAME RENDERING

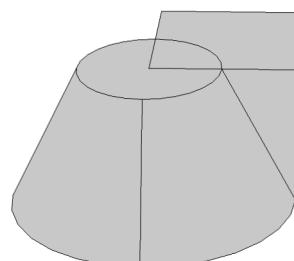

The following are available for 3D models.

BUTTON	NAME	ACTION
	Scene Light	Click any plot under Results . In the Graphics window or any other plot window, click the Scene Light button to turn it on. Click again to turn scene light off. See Figure 6-10 . When creating a View , this action toggles the Scene light check box on the View page.
	Transparency	Click any plot under Results . In the Graphics window or any other plot window, click the Transparency button to turn it on. Click again to turn transparency off. See Figure 6-10 . When creating a View , this action toggles the Transparency check box on the View page. See User-Defined Views .
	Orthographic Projection	Click this button to use orthographic projection; otherwise, perspective projection is used.
	Wireframe Rendering	Click any plot under Results . In the Graphics window, click the Wireframe Rendering button to turn it on. Click again to turn the wireframe off. See Figure 6-10 . Note that wireframe rendering only has effect when mesh rendering is turned off (for a view that normally shows the mesh). When creating a View , this action toggles the Wireframe rendering check box on the View page. See User-Defined Views . See also Preferences Settings to set the level of graphic detail to Wireframe and speed up the rendering of complex models or to improve visual appearance.

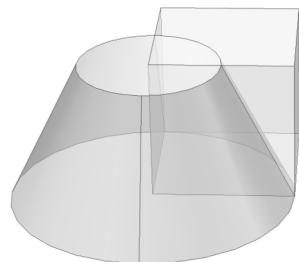

Scene light on and Transparency off

Scene light off

Transparency on

Wireframe rendering on

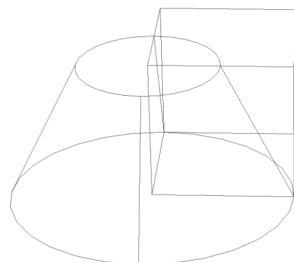

Figure 6-10: Scene light, transparency, and wireframe rendering examples.

HIDING AND SHOWING GEOMETRIC ENTITIES

Selecting an item in any **Selection** list highlights the corresponding geometric entities or objects in the **Graphics** window for selection or deselection. Only the geometric entities you can see in the **Graphics** window are available

for selection; that is, hidden objects cannot be selected and selection methods vary based on the Component's space dimension.

BUTTON	NAME	ACTION
	Click and Hide	<p>In the Graphics window, toggle the Click and Hide button (click to highlight and turn on and click again to turn off). When turned on, click on a geometric entity or geometry object, and it is then hidden and added to the list of hidden entities or hidden geometries in the Hide for Geometry or Hide for Physics node under a View. In the Selection lists, (hidden) appears next to the entity number. When click and hide is active, the cursor changes to indicate that clicking now hides objects: . See Figure 6-11.</p> <p>The click and hide functionality is turned off when you activate any of the following actions:</p> <ul style="list-style-type: none"> • Clicking an Active button in the Settings window (that is, activating or deactivating the selection). • Changing the selection in the Model Builder, manually or as a side effect of some other action such as adding a new feature. • In 2D, clicking a draw button such as Line, Rectangle, or Edit Object. <p>When creating a View, right-click the View node and select Hide for Geometry or Hide for Physics, depending on the current node in the model tree. Select a Geometric entity level from the list to hide.</p> <p>Also see Hide for Geometry, Hide for Physics, and Hide for Mesh Import when creating a View.</p>
	View Unhidden	In the Graphics window, click the View Unhidden button to display any geometry objects, domains, boundaries, edges, or points not hidden.
	View Hidden Only	In the Graphics window, click the View Hidden Only button to display only hidden geometry objects, domains, boundaries, edges, or points.
	View All	In the Graphics window, click the View All button to display all hidden and unhidden geometry objects, domains, boundaries, edges, or points.
	Reset Hiding	<p>In the Graphics window, click the Reset Hiding button to reset all hidden geometry objects, domains, boundaries, edges, or points to the default.</p> <p>This removes any Hide for Geometry or Hide for Physics subnodes added to a View node (when in geometry mode, Hide for Physics subnodes are not removed).</p>
		<p>When the View Hidden Only button () , View Unhidden button () , or View All button () is clicked on the Graphics window toolbar, it changes the view accordingly. The selection list on the Settings window details what is hidden or shown based on the button clicked. See Figure 6-11 and Figure 6-12 for examples based on the original geometry shown in About Highlighted Geometric Entities in the Graphics Window.</p>

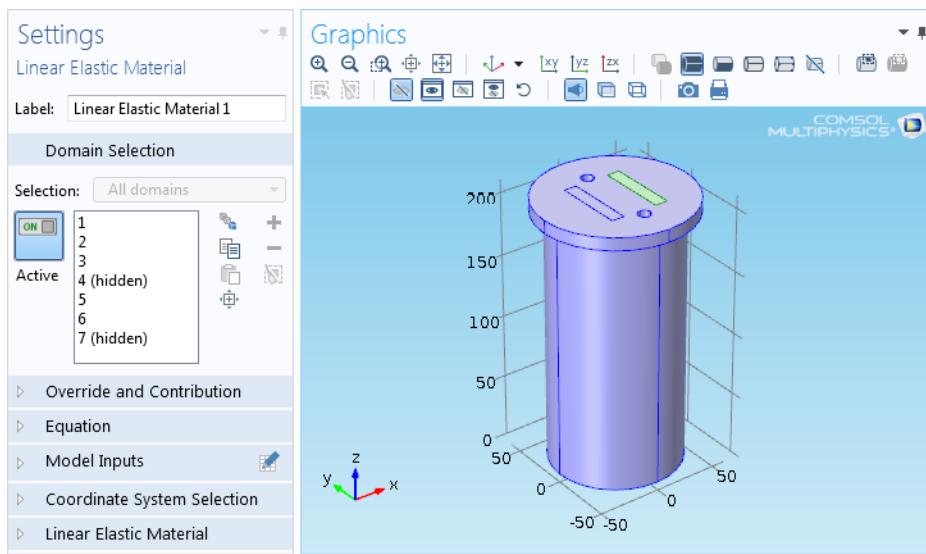

Figure 6-11: An example of the domains that display in the Graphics window when the View unhidden button is clicked. The selection list displays the detail that domains 4 and 7 are hidden in the Graphics window. Compare to Figure 6-12.

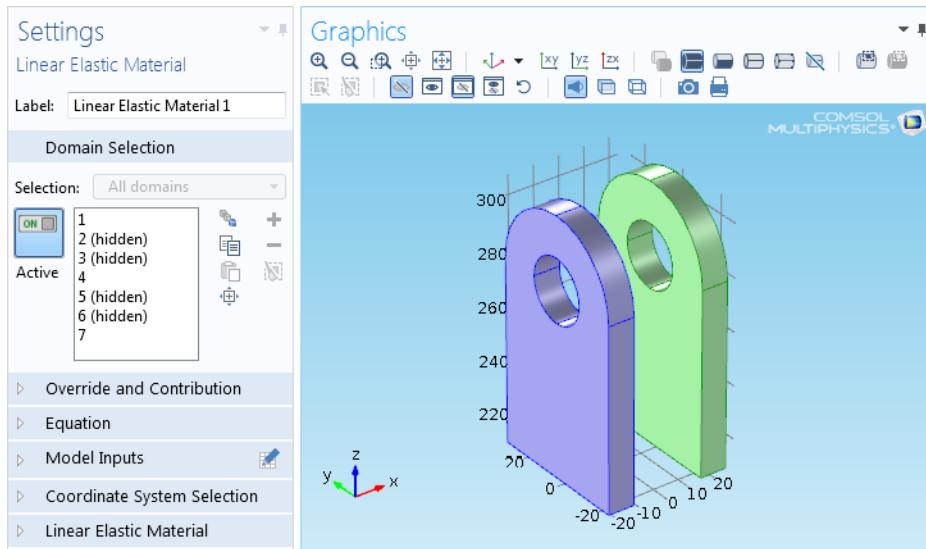

Figure 6-12: An example of the domains that display in the Graphics window when the View unhidden only button is clicked. The selection list displays the detail that domains 2, 3, 5, and 6 are hidden in the Graphics window. Compare to Figure 6-11.

Using A 3D Mouse from 3Dconnexion

The COMSOL Desktop on Windows supports the use of a 3D space mouse (SpaceMouse®) from 3Dconnexion® for mouse navigation.

To enable the 3D mouse support, select the **3Dconnexion space mouse** check box under **Mouse** on the **Graphics and Plot Windows** page in the **Preferences** dialog box.

If you want to change the setting of the SpaceMouse or customize the buttons, click **Open 3DConnexion Properties** in the tray icon of your space mouse. If you are a new user of a SpaceMouse, first run the SpaceMouse Training of the startup driver panel of your Space Mouse. You can then learn how to control your objects with the SpaceMouse.

In the settings for the SpaceMouse, you can specify the following personalized preferences:

- Speed: adapt the moving and rotating speed of the objects.
- Advanced Settings: In the Advanced Setting, you can control the speed of each degree of freedom, respectively. You can also disable the corresponding degree of freedom.
- Buttons: COMSOL Multiphysics has exposed a number of Actions/Commands; see, for example, commands in the Views section of the buttons settings page.
- Radial Menu: They can be useful in your Buttons section; you can bind your commands as you want.
- In the Buttons section, you can also bind a keyboard combination to trigger COMSOL actions; for example, Ctrl+O, which will trigger COMSOL Multiphysics to open a file.

PANNING AND ZOOMING IN 1D GRAPH PLOTS

For 1D graph plots, you can use the following mouse movements to pan and zoom (in addition to the zoom buttons; see [Zooming In and Out in the Graphics Window](#)):

- To pan in the x and y directions, right-click in the **Graphics** window and drag the mouse in the direction for the pan. Right-click to the left of the y -axis (outside the plot area) to pan in the y -direction only. Likewise, if the plot includes a secondary y -axis to the right, right-click to the right of the secondary y -axis (outside the plot area) to pan in the y -direction only for the quantity represented by the secondary y -axis. Right-click below the x -axis (outside the plot area) to pan in the x -direction only.
- To zoom in the x and y directions, middle-click in the **Graphics** window and drag the mouse to zoom in or out. Middle-click to the left of the y -axis (outside the plot area) to zoom in the y -direction only. Likewise, if the plot includes a secondary y -axis to the right, middle-click to the right of the secondary y -axis (outside the plot area) to zoom in the y -direction only for the quantity represented by the secondary y -axis. Middle-click below the x -axis (outside the plot area) to zoom in the x -direction only.

Creating Named Selections

Introduction

This section details how to create named selections to reuse throughout the model component when assigning material properties, boundary conditions, and other model settings.

You can create selection nodes under the Component node's **Definitions** node to represent various parts of the geometry and simplify the process of assigning materials, model equations, boundary conditions, and other model properties. These user-defined selections can be reused during modeling and named using descriptive titles — for example, **Tube**, **Wall**, or **Fluid**. Changes to the selection (for example, by adding or removing a boundary) updates all nodes in the Component that use that particular selection. You can also use a named selection to create a certain parts of the geometry that you want to hide from the view (see [Hide for Physics](#)).

Use the buttons listed in [Table 6-2](#) to create, copy, and paste selections. When there is the possibility of overlapping geometric entities, it is recommended that you use [The Selection List Window](#) to ensure the correct part of the geometry is selected.

There are different types of selections: [Explicit](#) selections, selections by enclosing part of the geometry by a bounding [Ball](#), [Box](#), or [Cylinder](#), Boolean selections ([Union](#), [Intersection](#), [Difference](#), and [Complement](#)), and selections of [Adjacent](#) geometric entities. To add selection nodes, right-click a **Definitions** node and choose from the **Selections** options as listed in [Table 6-6](#).

You can also right-click the **Geometry** node and choose from **Selections** options similar to those in [Table 6-6](#) for defining selections based on the geometry objects in the geometry sequence. See [Creating Named Selections in the Geometry Sequence](#).

The selections can be highlighted using a color scheme to make it easier to see the geometric entities that are included in a named selection. See [Selection Colors](#).

OPEN AN EXAMPLE MODEL WITH DEFINED EXPLICIT SELECTIONS

[Figure 6-13](#) uses a COMSOL Multiphysics Applications Libraries example, which includes several user-defined selections.

- 1 Open [The Application Libraries Window](#).
- 2 Navigate to the **COMSOL Multiphysics>Structural Mechanics>mast_diagonal_mounting** model file. Double-click to open it.
- 3 Expand the **Definitions** node under **Component 1**. Several nodes display in the **Model Builder**. Click the nodes shown in [Figure 6-13](#) to examine the list of geometric entities displayed in the **Settings** window for [Explicit](#).

In the selection **Settings** windows, also click the **Zoom to Selection** () button to zoom in on the selected geometric entities.

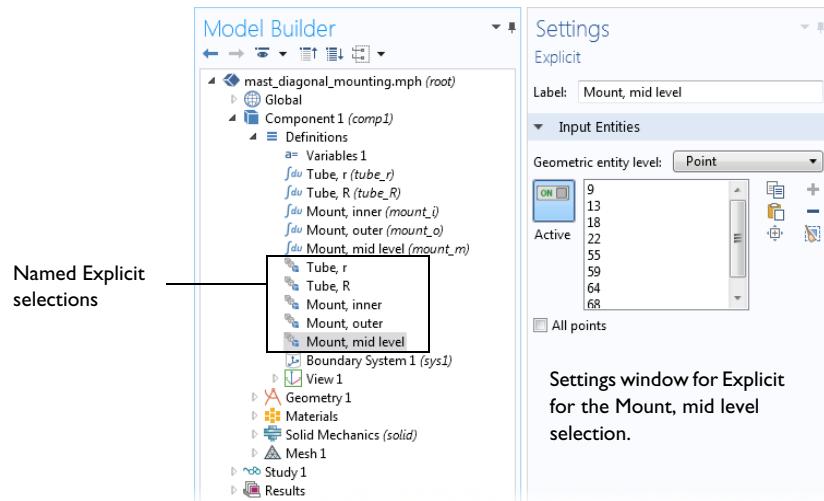

Figure 6-13: An example of an Explicit selection window for the Mount, mid level node. The Selection nodes under Definitions are renamed by the user.

THE TYPES OF NAMED SELECTIONS

TABLE 6-6: NAMED SELECTIONS BY TYPE

ICON	TYPE	DESCRIPTION
	Adjacent	Use the Adjacent node to create the selection as the adjacent geometric entities (boundaries, for example) to one or more selections.
	Ball	Use the Ball node to create the selection by enclosing part of the 3D geometry by a bounding ball (sphere) to select geometric entities that are partially or completely inside the ball.
	Box	Use the Box node to create the selection by enclosing part of the 3D geometry by a bounding box to select geometric entities that are partially or completely inside the box.
	Cylinder	Use the Cylinder node to create the selection by enclosing part of the 3D geometry by a bounding solid or hollow cylinder or cylinder segment to select geometric entities that are partially or completely inside the cylinder.
	Disk	Use the Disk node to create the selection by enclosing part of the 2D geometry by a bounding solid or hollow disk or disk segment to select geometric entities that are partially or completely inside the disk.
	Explicit	Use an Explicit node to create the selection using the normal selection tools for individual geometric entities (boundaries, for example) on the geometric entity level chosen.

Union, Intersection, Difference, and Complement

	Union	Use the Union node to create the selection as the union (addition) of two or more selections.
	Intersection	Use the Intersection node to create the selection as the intersection of two or more selections.
	Difference	Use the Difference node to create the selection as the difference between a set of one or more selections and another set of one or more selections.
	Complement	Use the Complement node to create the selection as the complement (inverse) of one or more selections.

|  | <ul style="list-style-type: none">• Grouping Nodes by Space Dimension and Type• Creating Named Selections in the Geometry Sequence• Working with Geometric Entities |
|---|---|

Creating Named Selections

There are several ways to create named selections. Toolbar buttons are available on **Settings** windows and **The Selection List Window** (see [Table 6-2](#)) to help group the geometric entities into manageable and easily identifiable selections that can be chosen from the **Selection** list on a **Settings** window, for example.

- [Create a Selection using the Definitions Node](#)
- [Create an Explicit Selection from a Settings Window](#)
- [Copying and Pasting Selection Lists](#)
- [Create an Explicit Selection from the Selection List Window](#)

CREATE A SELECTION USING THE DEFINITIONS NODE

There are several types of selections that can be created. For each type, choose to add it from the **Definitions>Selections** submenu. In the **Settings** window that opens, define the selection for that particular selection type. See [The Types of Named Selections \(Table 6-6\)](#) for a list and links to more information about the settings.

CREATE AN EXPLICIT SELECTION FROM A SETTINGS WINDOW

- 1 At any time during model creation, click a node that has the option to add a geometric entity to a selection, for example, under the **Materials** node or for the **Fixed Constraint** node for a **Solid Mechanics** interface as in [Figure 6-14](#).
- 2 In the **Settings** window that opens, select an option from the **Selection** list, for example, **Manual** or **All boundaries**.
- 3 Click the **Create Selection** button () and enter a **Selection name** in the **Create Selection** window, for example, **Fixed Constraint Boundaries**. Click **OK** or press enter.
- 4 In the **Model Builder** the new **Explicit** node (now named **Fixed Constraint boundaries**) is added under **Definitions**. After creating these named selections, the **Selection** list displays the name in the list as in [Figure 6-15](#).

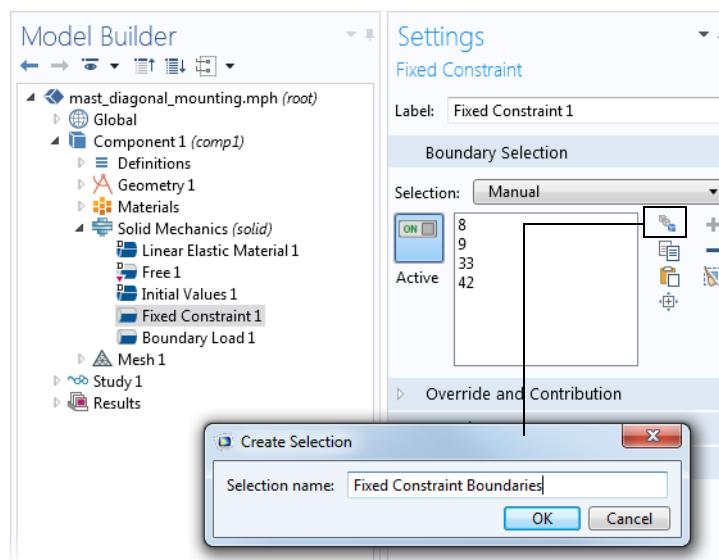

Figure 6-14: Creating a selection from the Settings window for a Fixed Constraint node.

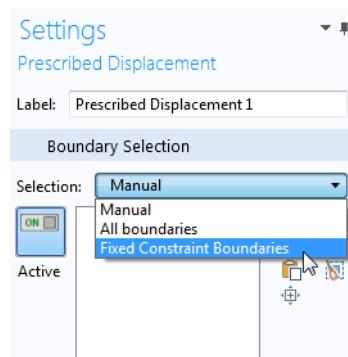

Figure 6-15: After creating these named selections, the Selection list displays the new name in the list, making it simple to choose it when adding additional boundary conditions such as a Prescribed Displacement node.

CREATE AN EXPLICIT SELECTION FROM THE SELECTION LIST WINDOW

Continue using the same model for this example, which demonstrates how to identify specific boundaries to add to a new Explicit selection:

- I In the **Model Builder**, click the **Component 1** node.

- 2 Open [The Selection List Window](#). Right-click and select **Float** to detach the window from the COMSOL Desktop.

COMSOL displays the geometric entities in the **Selection List** based on where in the model you are working. Other nodes can be clicked to display the list of geometric entities. For example, the **Materials**, **Solid Mechanics** (in this example), **Mesh**, and **Geometry** nodes. Experiment in the COMSOL Desktop by clicking on different nodes and observing the changes in the **Selection List** and **Graphics** windows.

- 3 In the **Graphics** window toolbar, click the **Select Boundaries** button (). The **Selection List** displays a list of all boundaries in the geometry. Click the **Select Domains**, **Select Edges**, or **Select Points** buttons in the **Graphics** window and observe how the list and the geometry changes based on the geometric entity level.
- 4 In the **Selection List** window, click to pick the boundaries you want to add to an **Explicit** selection:
- Click any individual boundary number in the list.
 - Shift-click to select contiguous items in the list.
 - Ctrl+click to select more than one boundary at a time.
- To help you identify the boundary, the boundaries that you picked are highlighted in red in the **Graphics** window.
- 5 Once the boundaries are chosen, click the **Create Selection** button () and enter a **Selection name** in the **Create Selection** window, for example, **Tube boundaries**. Click **OK** or press enter.
- 6 Go to the **Model Builder**. The new **Explicit** node (now named **Tube boundaries**) is added under **Definitions**.

Copying and Pasting Selection Lists

Another way to create selections is to copy and paste existing lists of geometry objects or geometric entities. If, for example, you have a list of geometric entities (boundaries, for example) in a file or document, you can copy it to the clipboard and then use Ctrl+V to directly paste that list into a selection list in a **Settings** window. An example of this is a list of geometric entity numbers described as a step in a modeling instruction. In geometry sequences, you can also copy and paste selections that include geometry object and geometric entities that are part of such geometry objects.

You can also use the **Copy Selection** button () and **Paste Selection** button () if you have a list of geometric entities that you want to paste into a selection list. Clicking **Copy Selection** () copies the current selection in that **Settings** window so that you can paste it into some other selection (for a compatibly geometry object or geometric entity level) in another **Settings** window. These buttons are available on many **Settings** windows as in [Figure 6-13](#) and [Figure 6-14](#) and in the **Selection List** window (except when in Geometry mode).

COPYING AND PASTING GEOMETRIC ENTITY INFORMATION INTO A SELECTION LIST

- 1 Prepare or copy the information to insert into the selection list. For example, copy a list of numbers from a text file or PDF file such as COMSOL model documentation (highlight and press Ctrl+C). Also copy a selection on any **Settings** window, (for example, the Fixed Constraint boundaries). Click the **Copy Selection** button () and go to the next step.
- 2 Click the **Paste Selection** button ().
- 3 In the **Paste Selection** window, paste (press Ctrl+V) or enter the list of geometric entities into the **Selection** field. Data in the list or entered in the field can include commas, semicolons, colons, tabs, and spaces as separators (1, 3), ranges (10–34), and words (*and*). For geometry objects, you can also use colons to separate the object and its entities. For example, in a boundary selection, typing cone1 1 4 arr1(2,1) 3 4 7 or, alternatively, cone1:

`1, 4; arr1(2,1): 3, 4, and 7`, both select boundaries 1 and 4 for the cone with the name `cone1` and boundaries 3, 4, and 7 for the array object `arr1(2,1)`. Click **OK** to paste the selection into the selection list.

Adjacent

An **Adjacent** () selection outputs selections adjacent to specified geometric entities or selections. For example, select all domains adjacent to some boundaries or all boundaries adjacent to some domains.

Two geometric entities that belong to different objects or different parts of an assembly are never adjacent.

The adjacent geometric entities can be of any type (domains, boundaries, edges, or points) regardless of the geometric entity level for the input selections. To add this node, right-click the **Definitions** node and choose **Selections>Adjacent**.

INPUT ENTITIES

Based on space dimension, select a **Geometric entity level** — **Domain**, **Boundary**, **Edge** (3D only), or **Point** for the selections to add or remove from the **Input selections** list and to create a selection of adjacent geometric entities. Click the **Add** button () to open an **Add** dialog box that contains selections of the chosen geometric entity level that appear earlier in the geometry sequence. Use the **Move Up** (), **Move Down** (), and **Delete** () buttons to organize the list.

OUTPUT ENTITIES

In the **Geometry entity level** list, choose the type of output entities: **Adjacent domains**, **Adjacent boundaries**, **Adjacent edges** (3D only), or **Adjacent points**. If the output entities have a lower dimension than the input entities, there are also two check boxes that you can use to select exterior and interior entities of the union of the input selections.

By default, only exterior entities are selected. For example, if the input selections are domains selections, and the output is adjacent boundaries, the **Exterior boundaries** (selected by default) and **Interior boundaries** check boxes display.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Adjacent Selection \(Geometry Sequences\)](#)

Ball

Another way to select 3D geometric entities is to define an enclosing **Ball** () to select geometric entities that are completely or partially inside the ball. To add this node, right-click the **Definitions** node and choose **Selections>Ball**.

GEOMETRIC ENTITY LEVEL

Select the **Level** for the geometric entities: **Domain**, **Boundary**, **Edge**, or **Point**.

If **Boundary** or **Edge** is selected, also select the **Group by continuous tangent** check box to extend the selection to all adjacent faces or edges that have continuous tangents (an angle less than the value in the **Angular tolerance** field) at their junctions (to select all faces that make up a continuous sheet, for example).

When the **Group by continuous tangent** check box is selected, set the tolerance on the continuity condition in the **Angular tolerance** field as the maximum angle between two faces or edges that are considered as having continuous tangents (a value between 0 and 180 degrees; the default value is 5 degrees).

See **Output Entities** for details about how the behavior depends on the condition for which the selection considers the group of entities to be enclosed.

INPUT ENTITIES

The **Entities** list defaults to **All**, which bases the selection on all entities of the selected type.

Select **From selections** to base the selection on other defined selections. Then, in the **Selections** list, add the selections for which you want to create a selection of geometric entities from those selections that are located within the ball that you define for the resulting selection. Click the **Add** button () to open an **Add** dialog box that contains selections of the chosen geometric entity level that appear earlier in the geometry sequence. Use the **Move Up** (), **Move Down** (), and **Delete** () buttons to organize the list.

BALL CENTER

Position the center of the ball by entering the center position in the **x**, **y**, and **z** fields (the unit is the length unit for the geometry).

BALL RADIUS

Enter the radius for the ball in the **Radius** field. The default is 0.

OUTPUT ENTITIES

For the selections made under **Input Entities**, define the dimension of the ball and select the condition for the geometric entities to be selected. Choose an option from the **Include entity if** list: **Entity intersects ball** (the default), **Entity inside ball**, **Some vertex inside ball**, or **All vertices inside ball**.

- If **Entity intersects ball** is kept as the default, it includes all geometric entities that intersect the enclosing ball; that is, the selection includes all entities that are partially or completely inside the ball. If in addition the **Group by continuous tangent** check box is selected for a boundary or edge under the **Geometric Entity Level** section, all entities in each group are selected if any entity in the group intersects the ball.
- For **Entity inside ball** it includes all geometric entities that are completely inside the enclosing ball. If in addition the **Group by continuous tangent** check box is selected for a boundary or edge under the **Geometric Entity Level** section, the entities in each group are selected only if all entities in the group are completely inside the ball.
- For **Some vertex inside ball** it includes all geometric entities where at least some vertex is inside the enclosing ball. If in addition the **Group by continuous tangent** check box is selected for a boundary or edge under the **Geometric Entity Level** section, all entities in each group are selected if any entity in the group has at least some vertex inside the ball.
- For **All vertices inside ball** it includes all geometric entities where all vertices are inside the enclosing ball. If the **Group by continuous tangent** check box is selected for a boundary or edge under the **Geometric Entity Level** section, the entities in each group are selected only if all entities in the group have all vertices inside the ball. This selection might differ slightly compared to when selecting **Entity inside ball** if the geometric entity is outside the ball at some points between the vertices.

The **Ball**, **Box**, **Cylinder**, and **Disk** selections use the rendering mesh to determine which entities fit the selection condition. You can control the detail for the rendering in the **Preferences** dialog box (select **Graphics and Plot Windows** and then use the **Detail** list under **Visualization**).

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Ball Selection \(Geometry Sequences\)](#)

Box

Another way to select geometric entities is to define an enclosing **Box** () to select geometric entities that are completely or partially inside the box. To add this node, right-click the **Definitions** node and choose **Selections>Box**.

See [Ball](#) for the **Geometric Entity Level** and **Input Entities** settings.

BOX LIMITS

Define the dimensions of the box by entering the maximum and minimum values in all directions in the **x minimum**, **x maximum**, **y minimum**, **y maximum**, and (for 3D) **z minimum** and **z maximum** fields. The unit is the length unit for the geometry. The default is **-Inf** and **Inf** for the minimum and maximum values, respectively; that is, the box encloses the entire geometry. Use **-Inf** or **Inf** in some of these settings to make the box only partially bounded.

OUTPUT ENTITIES

For the selections made under **Input Entities**, define the dimension of the box and select the condition for the geometric entities to be selected. Choose an option from the **Include entity if** list: **Entity intersects box** (the default), **Entity inside box**, **Some vertex inside box**, or **All vertices inside box**.

See [Ball](#) for the settings. The only difference is that the settings are for a **Box** instead of a **Ball**.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Box Selection \(Geometry Sequences\)](#)

Cylinder

Another way to select 3D geometric entities is to define an enclosing solid or hollow **Cylinder** () to select geometric entities that are completely or partially inside the cylinder. To add this node, right-click the **Definitions** node and choose **Selections>Cylinder**.

See [Ball](#) for the **Geometric Entity Level** and **Input Entities** settings.

SIZE AND SHAPE

Define the dimensions of the cylinder by entering the outer and inner radius and the positions of the upper and lower faces on the cylinder axis in the **Outer radius**, **Inner radius**, **Top distance**, and **Bottom distance** fields. The unit is the length unit for the geometry. The default is 0, 0, **Inf**, and **-Inf** for these settings, respectively. For a solid cylinder, leave the inner radius at 0. Making the inner and outer radius equal corresponds to a cylindrical surface. To define a sector of a full cylinder, use the **Start angle** (default: 0) and **End angle** (default: 360 degrees) fields. The selection includes entities that intersect or are contained in the cylinder sector (depending on the settings under **Output Entities** below).

POSITION

Position the cylinder by entering the center position in the **x**, **y**, and (for 3D) **z** fields. The default is 0 for all coordinates.

AXIS

Set the cylinder axis by choosing an **Axis type:** **z-axis** (the default), **x-axis**, **y-axis**, **Cartesian**, or **Spherical**. If **Cartesian** is selected, enter coordinates for **x**, **y**, and **z**. If **Spherical** is selected, enter angles for **theta** and **phi** (unit: deg).

OUTPUT ENTITIES

For the selections made under **Input Entities**, define the dimension of the cylinder and select the condition for the geometric entities to be selected. Choose an option from the **Include entity if list:** **Entity intersects cylinder** (the default), **Entity inside cylinder**, **Some vertex inside cylinder**, or **All vertices inside cylinder**.

See **Ball** for the settings. The only difference is that the settings are for a **Cylinder** instead of a **Ball**.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Cylinder Selection \(Geometry Sequences\)](#)

Disk

Another way to select 2D geometric entities is to define an enclosing **Disk** () to select geometric entities that are completely or partially inside the disk. To add this node, right-click the **Definitions** node and choose **Selections>Disk**.

GEOMETRIC ENTITY LEVEL

Select the **Level** for the geometric entities: **Domain**, **Boundary**, or **Point**.

If **Boundary** is selected, also select the **Group by continuous tangent** check box to extend the selection to all adjacent boundaries that have continuous tangents (an angle less than the value in the **Angular tolerance** field) at their junctions.

When the **Group by continuous tangent** check box is selected, set the tolerance on the continuity condition in the **Angular tolerance** field as the maximum angle between two boundaries that are considered as having continuous tangents (a value between 0 and 180 degrees; the default value is 5 degrees).

See **Output Entities** for details about how the behavior depends on the condition for which the selection considers the group of entities to be enclosed.

INPUT ENTITIES

The **Entities** list defaults to **All**, which bases the selection on all entities of the selected type.

Select **From selections** to base the selection on other defined selections. Then, in the **Selections** list, add the selections for which you want to create a selection of geometric entities from those selections that are located within the disk that you define for the resulting selection. Click the **Add** button () to open an **Add** dialog box that contains selections of the chosen geometric entity level that appear earlier in the geometry sequence. Use the **Move Up** (), **Move Down** (), and **Delete** () buttons to organize the list.

DISK CENTER

Position the center of the disk by entering the center position in the **x**, and **y** fields (the unit is the length unit for the geometry).

SIZE AND SHAPE

Define the dimensions of the disk by entering the outer and inner radius in the **Outer radius** and **Inner radius** fields. The unit is the length unit for the geometry. For a solid disk, leave the inner radius at 0. To define a sector of a full disk, use the **Start angle** (default: 0) and **End angle** (default: 360 degrees) fields. The selection includes entities that intersect or are contained in the disk sector (depending on the settings under **Output Entities** below).

OUTPUT ENTITIES

For the selections made under **Input Entities**, define the dimension of the disk and select the condition for the geometric entities to be selected. Choose an option from the **Include entity if** list: **Entity intersects disk** (the default), **Entity inside disk**, **Some vertex inside disk**, or **All vertices inside disk**.

- If **Entity intersects disk** is kept as the default, it includes all geometric entities that intersect the enclosing disk; that is, the selection includes all entities that are partially or completely inside the disk. If in addition the **Group by continuous tangent** check box is selected for a boundary under the **Geometric Entity Level** section, all entities in each group are selected if any entity in the group intersects the disk.
- For **Entity inside disk** it includes all geometric entities that are completely inside the enclosing disk. If in addition the **Group by continuous tangent** check box is selected for a boundary under the **Geometric Entity Level** section, the entities in each group are selected only if all entities in the group are completely inside the disk.
- For **Some vertex inside disk** it includes all geometric entities where at least some vertex is inside the enclosing disk. If in addition the **Group by continuous tangent** check box is selected for a boundary under the **Geometric Entity Level** section, all entities in each group are selected if any entity in the group has at least some vertex inside the disk.
- For **All vertices inside disk** it includes all geometric entities where all vertices are inside the enclosing disk. If the **Group by continuous tangent** check box is selected for a boundary under the **Geometric Entity Level** section, the entities in each group are selected only if all entities in the group have all vertices inside the disk. This selection might differ slightly compared to when selecting **Entity inside disk** if the geometric entity is outside the disk at some points between the vertices.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Disk Selection \(Geometry Sequences\)](#)

Explicit

Use an **Explicit** node () to create the selection using the selection tools for individual geometric entities (boundaries, for example) on the chosen geometric entity level. To add this node, right-click the **Definitions** node and choose **Selections>Explicit**.

INPUT ENTITIES

Based on space dimension, select a **Geometric entity level**: **Domain**, **Boundary**, **Edge**, or **Point** for the geometric entities to add or remove from the selection list.

Select and add geometric entities in the **Graphics** window, using other selection methods, or by selecting the **All domains**, **All boundaries**, **All edges**, or **All points** check box. The selected items are highlighted in the **Graphics** window. Selecting the check box for all geometric entities locks all entities of this type as selected even if the geometry changes.

If **Boundary** (for 2D and 3D models) or **Edge** is selected, also select the **Group by continuous tangent** check box to extend the selection to all adjacent faces or edges that have continuous tangents (an angle less than the value in the **Angular tolerance** field) at their junctions. This grouping makes it possible to select all faces that make up a continuous sheet, for example. When the **Group by continuous tangent** check box is selected, set the tolerance on the continuity condition in the **Angular tolerance** field as the maximum angle between two faces or edges that are considered as having continuous tangents (a value between 0 and 180 degrees; the default value is 5 degrees).

To deselect one or some of the faces or edges that make up the group with continuous tangents, first clear the **Group by continuous tangent** check box.

OUTPUT ENTITIES

Define the geometry objects that the selection contains. The options available and defaults depend on the selection in the **Geometric entity level** list as well as the space dimension of the Component.

If **Domain** is the input the default output is the **Selected domains**.

- Select **Adjacent boundaries**, **Adjacent edges**, or **Adjacent points** to use the boundaries, edges, or points next to the selected domains as the selection output (available options depend on the space dimension of the Component). This makes it possible to, for example, make a selection of all boundaries around a domain by first selecting the domain.
- Depending on the selection output, choose to include **Exterior boundaries** (the default) or **Interior boundaries**; **Exterior edges** (the default) or **Interior edges**; or **Exterior points** (the default) or **Interior points**. Click to select or clear the check boxes as needed.

If **Boundary** or **Edge** are chosen as the input, the default output is the **Selected boundaries** or **Selected edges**, respectively. As with the **Domain** input, select other options as needed. The **Point** output is the same as the selection input (that is, the selected points).

If a particular selection is used elsewhere in the model, including in other selections, it is not possible to change the output type, for example, from domains to boundaries.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Explicit Selection \(Geometry Sequences\)](#)

Union, Intersection, Difference, and Complement

Boolean selections — **Union** (), **Intersection** (), **Difference** (), and **Complement** () — are useful to combine two or more selections (union), create a selection of overlapping geometric entities (intersection), create selection of entities that are in one selection but not in another (difference), and to create a selection as the inverse (complement) of one or more selections (all boundaries except the inflow boundaries, for example). The complement can be convenient if a selection is needed that consists of all boundaries except one or a few. Then it is easier to first create a selection (just the one boundary, for example) and then use a **Complement** node to create its complement. All Boolean selection nodes' **Settings** windows have similar sections. To add this node, right-click the **Definitions** node and choose an option from the **Selections** menu.

GEOMETRIC ENTITY LEVEL

Based on space dimension, select a **Level** — **Domain**, **Boundary**, **Edge** (3D only), or **Point** for the selections to add or remove from the **Selections to add** (**Selections to intersect**, **Selections to subtract**, **Selections to invert**) list.

INPUT ENTITIES

Use the buttons in this section to move, add, or delete selections in the **Selections to add** (Union), **Selections to intersect** (Intersection), or **Selections to invert** (Complement) lists. For the **Difference** selection node also choose **Selections to subtract**. Click the **Add** button (+) to open an **Add** dialog box that contains all existing selections for the same geometric entity level. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** (Delete) buttons to organize the list.

COLOR

In this section, choose a color from the **Color** list for use with this selection. See [Selection Colors](#).

- [Creating Named Selections in the Geometry Sequence](#)
- [Union Selection, Intersection Selection, Difference Selection, and Complement Selection \(Geometry Sequences\)](#)

Creating Named Selections in the Geometry Sequence

You can also create selection nodes in the geometry sequence for user-defined named selections of all or a few of the geometric entities at a specific geometric entity level based on one or more of the nodes above the selection node in the geometry sequence. This way it is possible to make a selection that only includes a few of the geometric entities from one or more geometry objects and also create selections based on entire geometry objects. Using selections based on a geometry object makes it possible to track, for example, all boundaries in the final geometry that belong to that geometry object, even if its original boundaries are intersected by other geometry objects during a parametric sweep, for example. That is, the selection nodes in the **Geometry** branch can provide better associativity when changing or updating the geometry than the corresponding selection nodes under **Definitions**. See the following sections for details on the selection nodes in the geometry sequence, which you choose from the **Selections** submenu in the **Geometry** node's context menu.

- [Working with Geometry Sequences](#)
- [Creating Named Selections](#)

BUILDING SELECTION NODES

If the current node in the geometry sequence is before the node preceding the selection node or after the selection node, the selection is not visualized (because the selected object or entities might not be visible in this state). In this case, the **Build Preceding State** button appears instead of the selection list (this also applies for nonexplicit selections in some selection nodes if **From selections** is selected under **Input Entities**). To create a state in which the selection can be visualized, click **Build Preceding State** or click the **Build Selected** button (Build Selected). To rebuild the entire geometry, click the **Build All Objects** button (Build All Objects).

CREATING SELECTIONS FROM GEOMETRIC PRIMITIVES AND OPERATIONS

For all geometric primitives in 3D, 2D, and 1D geometries — for example, blocks, spheres, squares, polygons, and intervals — as well as for all geometry operations — for example, union, intersection, fillet, array, and mirror — you can create selections for each type of geometric entity that the resulting geometry objects consist of. The following list shows the geometric entity types for geometry objects that are “solids”:

- In 3D: domains, boundaries, edges, and points

- In 2D: domains, boundaries, and points
- In 1D: domains and points

To create these selections, click the geometry object node in the **Model Builder** and then select the **Resulting objects selection** check box in the **Settings** window's **Selections of Resulting Entities** section. The selections then become available with the name of the geometry node (**Block 1**, for example) in subsequent geometry nodes. To make the selections available in all applicable selection lists in the **Settings** windows for the physics nodes, material nodes, mesh nodes, and so on, select an option from the **Show in physics (Show in instances if in a geometry part)** list: **All levels**, to make the selection available for all geometric entity levels; **Domain selection** (the default for most nodes); **Boundary selection**; **Edge selection** (3D only); **Point selection**; or **Off**, if the selection should not be available outside of the geometry sequence. Not all entity levels are available for all geometric primitives and operations. There are no explicit Selection nodes for these selections. For example, for a 3D Component model with a single **Block** node, the **Selection** list contains the selection **Block 1**, which for a domain selection is the single domain, and for a boundary selection consists of the six faces of the block.

The Ball (3D and 2D), Box, and Cylinder (3D) selections are coordinate-based selections where you define the coordinates of a volume, area, or interval to create selections of entities enclosed by the part of the geometry defined by the selection.

TABLE 6-7: GEOMETRY NAMED SELECTIONS BY TYPE

ICON	TYPE	DESCRIPTION
	Adjacent Selection	Use this node to create the selection as the adjacent geometric entities (boundaries, for example) to one or more selections. See Adjacent Selection (Geometry Sequences) .
	Ball Selection	Use this node to create the selection by enclosing part of the 3D geometry by a bounding ball (sphere) to select geometric entities that are partially or completely inside the ball. See Ball Selection (Geometry Sequences) .
	Box Selection	Use this node to create the selection by enclosing part of the 3D geometry by a bounding box to select geometric entities that are partially or completely inside the box. See Box Selection (Geometry Sequences) .
	Cylinder Selection	Use this node to create the selection by enclosing part of the 3D geometry by a bounding solid or hollow cylinder or cylinder section to select geometric entities that are partially or completely inside the cylinder. See Cylinder Selection (Geometry Sequences) .
	Disk Selection	Use this node to create the selection by enclosing part of the 2D geometry by a bounding solid or hollow disk or disk section to select geometric entities that are partially or completely inside the disk. See Disk Selection (Geometry Sequences) .
	Explicit Selection	Use this node to create the selection using the normal selection tools for individual geometric entities (boundaries, for example) on the geometric entity level chosen. See Explicit Selection (Geometry Sequences) .

[Union Selection, Intersection Selection, Difference Selection, and Complement Selection \(Geometry Sequences\)](#)

	Union Selection	Use this node to create the selection as the union (addition) of two or more selections.
	Intersection Selection	Use this node to create the selection as the intersection of two or more selections.

TABLE 6-7: GEOMETRY NAMED SELECTIONS BY TYPE

ICON	TYPE	DESCRIPTION
	Difference Selection	Use this node to create the selection as the difference between a set of one or more selections and another set of one or more selections.
	Complement Selection	Use this node to create the selection as the complement (inverse) of one or more selections.

Adjacent Selection (Geometry Sequences)

The **Adjacent Selection** () node selects all entities of a given dimension that are adjacent to entities in a given set of selections (having another dimension). For example, it can select all boundaries adjacent to a given domain selection. To add this node, right-click the **Geometry** node and choose **Selections>Adjacent Selection**.

Two geometric entities that belong to different parts of an assembly are never adjacent.

See [Adjacent](#) for the **Input Entities** and **Output Entities** settings, which are the same.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Adjacent](#)

Ball Selection (Geometry Sequences)

Another way to select geometry objects or geometric entities is to use an enclosing **Ball Selection** () to select objects or entities that are completely or partially inside the ball in 3D. To add this node, right-click the **Geometry** node and choose **Selections>Ball Selection**.

See [Ball](#) for all settings. You can also choose **Object** as the **Level** under **Geometric Entity Level**.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Ball, Box, and Cylinder](#)

Box Selection (Geometry Sequences)

Another way to select geometry objects or geometric entities is to use an enclosing **Box Selection** () to select objects or entities that are completely or partially inside the box (in 3D), rectangle (in 2D), or interval (in 1D). To add this node, right-click the **Geometry** node and choose **Selections>Box Selection**.

See **Ball** for the **Geometric Entity Level**, **Input Entities** and **Output Entities** settings. See **Box** for the **Box Limits** settings.

- You can also choose **Object** as the **Level** under **Geometric Entity Level**.
- For the **Output Entities** settings, note that the settings are for a **Box** instead of a **Ball**.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection**

window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Ball, Box, and Cylinder](#)

Cylinder Selection (Geometry Sequences)

Another way to select geometry objects or geometric entities is to use an enclosing **Cylinder Selection** () to select objects or entities that are completely or partially inside the cylinder (in 3D only). To add this node, right-click the **Geometry** node and choose an option from the **Selections** menu.

See [Ball](#) for the **Input Entities** and **Output Entities** settings. See [Cylinder](#) for the **Size and Shape**, **Position**, and **Axis** settings.

- You can also choose **Object** as the **Level** under **Geometric Entity Level**.
- For the **Output Entities** settings, note that the settings are for a **Cylinder** instead of a **Ball**.

GEOMETRIC ENTITY LEVEL

Select the **Level** for the geometric entities: **Domain**, **Boundary**, **Edge**, or **Point**.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Cylinder](#)

Disk Selection (Geometry Sequences)

Another way to select geometry objects or geometric entities is to use an enclosing **Disk Selection** () to select objects or entities that are completely or partially inside a disk in 2D. To add this node, right-click the **Geometry** node and choose **Selections>Disk Selection**.

See [Disk](#) for all settings. You can also choose **Object** as the **Level** under **Geometric Entity Level**.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Disk, Box, and Cylinder](#)

Explicit Selection (Geometry Sequences)

Use an **Explicit Selection** node () to create the selection using the selection tools for individual geometry objects or geometric entities (boundaries, for example). To add this node, right-click the **Geometry** node and choose **Selections>Explicit Selection**.

ENTITIES TO SELECT

Based on space dimension, select a **Geometric entity level**: **Object**, **Domain**, **Boundary**, **Edge**, or **Point** for the geometric objects or entities to add to the selection list.

Select and add geometric entities in the **Graphics** window or using other selection methods. The selected items are highlighted in the **Graphics** window.

If **Boundary** (for 2D and 3D models) or **Edge** is selected, also select the **Group by continuous tangent** check box to extend the selection to all adjacent faces or edges that have continuous tangents (an angle less than the value in the **Angular tolerance** field) at their junctions to select all faces that make up a continuous sheet, for example. When the **Group by continuous tangent** check box is selected, set the tolerance on the continuity condition in the **Angular tolerance** field as the maximum angle between two faces or edges that are considered as having continuous tangents (a value between 0 and 180 degrees; the default value is 5 degrees).

If a particular selection is used elsewhere in the model, including in other selections, it is not possible to change the geometric entity level, for example, from domains to boundaries.

To deselect one or some of the faces or edges that make up the group with continuous tangents, first clear the **Group by continuous tangent** check box.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- [Creating Named Selections](#)
- [Cumulative Selections](#)
- [Explicit](#)

Union Selection, Intersection Selection, Difference Selection, and Complement Selection (Geometry Sequences)

Boolean selections — **Union Selection** (), **Intersection Selection** (), **Difference Selection** (), and **Complement Selection** () — are useful to combine two or more selections (union), create a selection of entities that are common to the input selections (intersections), create selection of entities that are in one selection but not in another (difference), and to create a selection as the complement (inverse) of one or more selections (all boundaries except the inflow boundaries, for example). The complement can be convenient if a selection is needed that consists of all boundaries except one or a few. Then it is easier to first create a selection (just the one boundary, for example) and then use a **Complement** node to create its complement. All Boolean selection nodes' **Settings** windows have similar sections. To add this node, right-click the **Geometry** node and choose an option from the **Selections** menu.

GEOMETRIC ENTITY LEVEL

Based on space dimension, select a **Level** — **Object**, **Domain**, **Boundary**, **Edge** (3D only), or **Point** for the selections to add or remove from the **Selections to add** (**Selections to intersect**, **Selections to subtract**, and **Selections to invert**) list.

INPUT ENTITIES

Use the buttons in this section to move, add, or delete selections in the **Selections to add** (Union), **Selections to intersect** (Intersection), or **Selections to invert** (Complement) lists. For the **Difference** selection node, also choose **Selections to subtract**. Click the **Add** button () to open an **Add** dialog box that contains all existing selections for the same geometric entity level. Use the **Move Up** (), **Move Down** (), and **Delete** () buttons to organize the list.

RESULTING SELECTION

By default, the **Keep selection** check box is selected. Clear the check box if you do not want the resulting selection to be available as a named selection in other nodes in the geometry sequence or other parts of the model tree. If the **Keep selection** check box is selected, you can also determine if the selection should appear in applicable settings

for physics, materials, and other parts of the model tree outside of the geometry using the **Show in physics** list (or **Show in instances** if the selection is in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component). If the geometric entity level is not set to **Object** (any of **Domain**, **Boundary**, **Edge**, or **Point**), choose **On** (the default) or **Off** to show the selection in physics and other settings or not. If the geometric entity level is **Object**, choose one of **All levels** (that is, all entity levels), **Object selection** (in geometry parts only), **Domain selection**, **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off**. For **Show in physics**, **All levels** is the default; for **Show in instances**, **Object selection** is the default.

Cumulative Selection

From the **Contribute to** list, choose an option. In addition to available **Cumulative Selection** nodes, **None** is always available from the list. To create a new **Cumulative Selection**, click **New**. Enter a **Name** in the **New Cumulative Selection** window. Click **OK** or press enter. This new cumulative selection is now available from any **Contribute to** list for a geometry selection.

- Creating Named Selections
- Cumulative Selections
- Union, Intersection, Difference, and Complement

Cumulative Selections

A *cumulative selection* is a selection in the geometry sequence that is a union of contributions from other selections. Cumulative selections are especially useful to construct a selection that has different definitions in different branches of an If clause. You can also use them as an alternative to a Union Selection node. **Cumulative Selection** nodes (for each cumulative selection appear under **Cumulative Selections** () at the bottom of the geometry sequence under **Geometry**. For example, a Circle node creates four associated cumulative selections, which all have the same label (for example, Cumulative Selection 1). They appear with different labels under **Cumulative Selections: Cumulative Selection 1 (Object)**, **Cumulative Selection 1 (Domain)**, **Cumulative Selection 1 (Boundary)**, and **Cumulative Selection 1 (Point)**. On the other hand, when you use the **Contribute to** list in a selection node, for example, only one **Cumulative Selection** node is created for the geometric entity level for that selection. When you select a **Cumulative Selection** node, the corresponding geometry objects or geometric entities appear in yellow in the **Graphics** window.

In the **Settings** window for **Cumulative Selection** nodes, you can rename a cumulative selection using the **Label** field. All **Cumulative Selection** nodes except those for the **Object** level also include the following section:

RESULTING SELECTION

Select the **Show in physics** check box (the **Show in instances** check box in geometry parts; **Show in 3D** in a plane geometry under a work plane in a 3D component) to make the cumulative selection available in physics, materials, and other applicable settings outside of the geometry sequence. This check box is selected by default.

CONTRIBUTING TO CUMULATIVE SELECTIONS

For a selection geometry feature, you can let it contribute to an existing cumulative selection by choosing an existing cumulative selection in the **Contribute to** list in its **Resulting Selection** section. To let it contribute to a new cumulative selection, click the **New** button.

For a geometry feature that has a **Selections of Resulting Entities** section in its **Settings** window, you can similarly let the resulting entities contribute to a cumulative selection by choosing an existing cumulative selection in the **Contribute to** list or clicking the **New** button.

You can also create a new cumulative selection by right-clicking the **Cumulative Selections** node and select **Cumulative Selection**. New **Cumulative Selection** nodes then appear.

To remove a contribution to a cumulative selection, select **None** in the **Contribute to** list.

To remove a cumulative selection, right-click any **Cumulative Selection** node that belongs to that cumulative selection and select **Delete** (). You can also right-click the main **Cumulative Selections** node and select **Delete Unused Selections** () to delete all cumulative selections that are not used.

User-Defined Views

Views provide the camera setting, grid, rendering, arrows, lighting, and transparency in the **Graphics** window. You can create and use several user-defined views to highlight and display the geometry in different ways. By default a **View** node is added to all space dimensions, except for 0D components. For any dimension, also right-click the **View** node to add **Hide for Geometry** nodes.

For 1D, 1D axisymmetric, 2D, and 2D axisymmetric models, an **Axis** () subnode is also added where you can set the axis coordinates and manual spacing. The **View** nodes and subnodes have information about a view, and you can also control the settings to display or hide geometry labels, direction arrows, and lock the axis. See [Axis \(2D and 2D Axisymmetric\)](#), [Axis \(1D and 1D Axisymmetric\)](#), and [View \(1D and 2D\)](#).

For 3D models, a **Camera** subnode () and three **Directional Light** nodes (), including default settings, are also added. The **View** node and subnodes have information about a view. The settings include (in addition to, for example, settings for displaying geometry labels and direction arrows) transparency, lighting sources, lighting attributes, and camera settings. See [View \(3D\)](#).

	To display the Views node () under Results (), click the Show button () and select Advanced Results Options . You can then right-click that node to add extra 2D View () and 3D View () nodes. This can be useful, for example, when 2D axisymmetric revolved plots or 2D cut plane plots for 3D models are created or when you want to view the result plots showing the entire geometry and some zoomed-in part. The View node () also appears when you add a new view from the plot settings in 2D or 3D plot groups.
	Right-click Definitions () and select View to create additional View nodes and then experiment by switching views to find the best way to illustrate a model. Views can be selected from the list of views () in the Graphics window toolbar. To reset the View node settings and its subnodes to the defaults, right-click View and select Reset to Default ()

View (1D and 2D)

For 1D, 1D axisymmetric, 2D, and 2D axisymmetric components, the **View** node () controls the settings to display or hide labels, grid, and other parts of the view and to lock the axis. An **Axis** node is added by default. You can add this **View** node by right-clicking **Definitions** in a 1D or 2D component and also by right-clicking **Views** under **Results** to add a **View 2D** node.

Also right-click the **View** node in the component to add **Hide for Geometry**, **Hide for Physics**, or **Hide for Mesh Import**, depending on your current view. To add additional **View** nodes, in the **Model Builder**, right-click **Definitions** and select **View**. You can also right-click a **View** node to copy or duplicate it. Right-click the **Definitions** or **Views** container node above the **View** nodes to paste a copied **View** node.

VIEW

Select the **Show geometry labels** check box to display the geometry object labels and the geometric entity labels (numbering) in the **Graphics** window. The labels appear for geometry objects or geometric entities (domain, boundary, edge, or point numbers), depending on what part of the model tree you display and the selection mode you are using.

Select the **Show edge direction arrows** check box to display the direction arrows on boundaries (edges) in the **Graphics** window. The direction arrows indicate the directions in which the boundary parameterization's value increases.

The **Show grid** check box (available in 2D) is selected by default. Clear it to remove the grid for the view in the Graphics window.

The **Mesh rendering** check box (available in 2D) is selected by default. Clear it to not plot the mesh in the mesh mode only, so there may not be an immediate effect when you select or clear this check box. This check box is not available in work-plane views, geometry part views, and result views.

Clear the **Show axis units** check box if you do not want to include units for the plot axes.

Select the **Lock axis** check box to store the current axis limits so that, for example, the zoom tools can be temporarily used. By revisiting the **View** node you can then restore the axis limits to the values in the view at the time the **Lock axis** check box is selected.

COLORS (2D ONLY)

Clear the **Show selection colors** check box if you do not want to include colors indicating user-defined selections.

Select the **Show material colors and texture** check box if you want to include colors and texture indicating the material used in the geometry.

-
- | | |
|--|--|
|  | <ul style="list-style-type: none">• View Toolbar• Axis (2D and 2D Axisymmetric)• Axis (1D and 1D Axisymmetric)• View (3D) |
|--|--|

Axis (2D and 2D Axisymmetric)

For 2D and 2D axisymmetric components, the **View** node has an **Axis** () subnode where you specify axis limits and grid spacing, and control the view scale (aspect ratio) for the plots.

-
- | | |
|---|---|
|  | <ul style="list-style-type: none">• View Toolbar• View (1D and 2D)• View (3D)• Axis (1D and 1D Axisymmetric) |
|---|---|

AXIS

Enter **x minimum**, **x maximum**, **y minimum**, and **y maximum** values for the axis limits.

The default setting in the **View scale** list is **None**, which makes the increments equal in the *x*- and *y*-directions. Select **Automatic** to make the geometry fill the graphics window with unequal increments. This can be useful when working with thin and slender geometries. Select **Manual** to specify the view scale in the **x scale** and **y scale** text fields. Equal values, such as 1, make the geometries appear with the correct aspect ratio. The default values represent the view scale of the previous setting in the **View scale** list.

GRID

Select the **Manual spacing** check box and enter **x spacing** and **y spacing** values to control the grid spacing manually. Enter **Extra x** and **Extra y** values directly or click the **Range** button () as needed.

The default precision for the 2D grid axes labels is four digits. You can change the precision in [The Preferences Dialog Box](#), using the **2D axis** field under **Display format (maximum number of digits)** on the **Graphics and Plot Windows** page.

Axis (1D and 1D Axisymmetric)

For 1D and 1D axisymmetric, the **View** node has an **Axis** () subnode where you specify axis limits and grid spacing, and control the view scale (aspect ratio) for the plots.

AXIS

Enter **x minimum** and **x maximum** values for the axis limits.

GRID

Select the **Manual spacing** check box and enter an **x spacing** value to control the grid spacing manually. Enter an **Extra x** value directly or click the **Range** button () as needed.

- [View Toolbar](#)
- [View \(1D and 2D\)](#)
- [View \(3D\)](#)
- [Axis \(2D and 2D Axisymmetric\)](#)

View (3D)

The **View** node () for 3D components has many options to add light sources and define the light attributes. Other functions include displaying or hiding geometry labels, transparency, wireframe rendering, a numbered grid, and axis orientation in the **Graphics** window. See [Figure 6-16](#). You can add this **View** node by right-clicking **Definitions** in a 3D component and also by right-clicking **Views** under **Results** to add a **View 3D** node.

Also right-click the **View** node in the component to add [Hide for Geometry](#), [Hide for Physics](#), or [Hide for Mesh Import](#), depending on your current view.

- [View Toolbar](#)
- [User-Defined Views](#)
- [View \(1D and 2D\)](#)
- [About the 3D View Light Sources and Attributes](#)

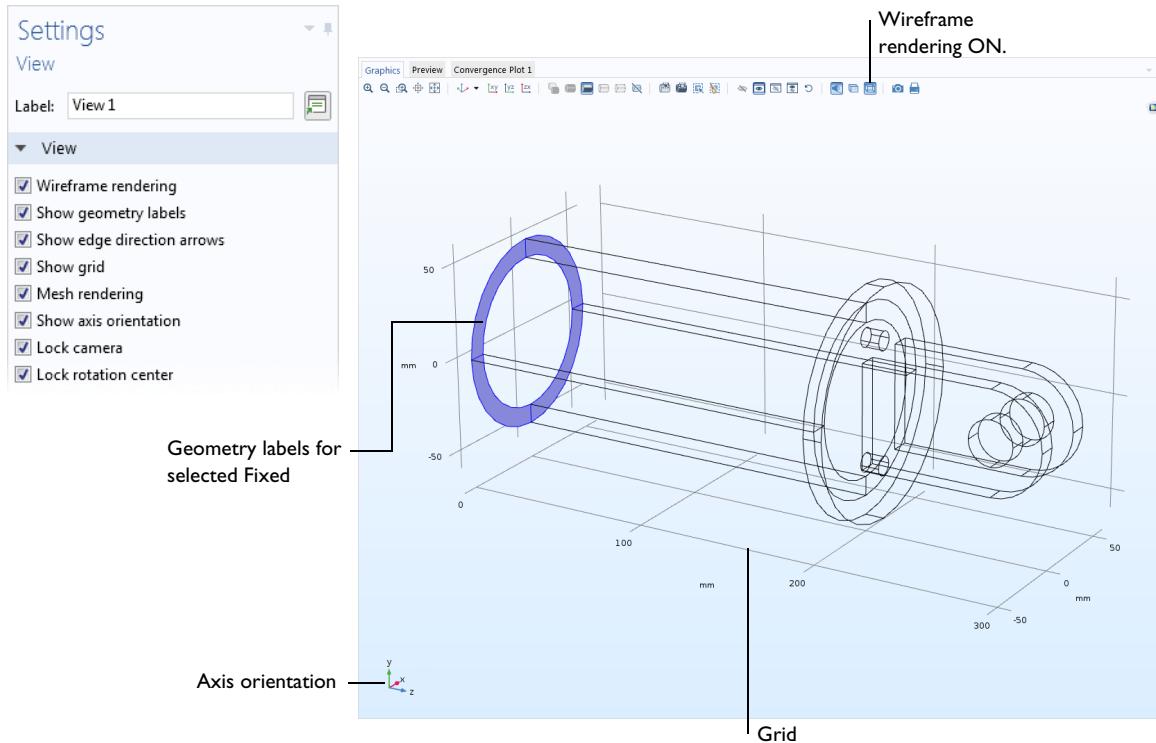

Figure 6-16: An example of the top of the 3D Settings window for View with all View option check boxes selected. The Graphics window shows what the check boxes represent. In this example, using the Diagonal Mounting Detail of a Communication Mast model, the Fixed Constraint node is clicked in the Model Builder, which then displays the numbers associated to the boundaries (8, 9, 33, and 42). Compare to the boundary numbers shown in Figure 6-14, which is for the same node. The edge direction arrows are not displayed in this view.

Also right-click the **View** node in the component to add [Hide for Geometry](#), [Hide for Physics](#), or [Hide for Mesh Import](#), depending on your current view.

The **View** node (for 3D models has the following sections:

VIEW

Select the **Wireframe rendering** check box to view the edges of the object as solid lines. The **Wireframe Rendering** button () is turned on or off in the **Graphics** window at the same time. Wireframe rendering only has effect when mesh rendering is turned off (for a view that normally shows the mesh).

Select the **Show geometry labels** check box to display the geometric object names in the **Graphics** window. The labels appear for geometry objects or geometric entities (boundary, edge, or point numbers, but not domain numbers), depending on what part of the model tree you display and the selection mode you are using. If you use wireframe rendering, no labels appear.

Select the **Show edge direction arrows** check box to display direction arrows on edges in the **Graphics** window. The direction arrows indicate the directions for which the edge parameterization values increase.

By default, the **Show grid** check box is selected and displays a numbered grid in the **Graphics** window around the object. Click to clear the check box to hide the grid.

By default, the **Mesh rendering** check box is selected. Clear it to not render the mesh, where the mesh normally appears, which can be useful, for example, to get a better view of the inside of complex meshed 3D geometries. This check box is not available in geometry part views and result views.

By default, the **Show axis orientation** check box is selected and the axis orientation indicator for the global Cartesian coordinate directions is displayed in the lower-left corner of the **Graphics** window. Click to clear the check box to hide the axis orientation indicator.

By default, the **Show axis units** check box is selected. Click to clear the **Show axis units** check box if you do not want to include units for the plot axes.

Select the **Lock camera** check box to store the current camera settings so that the zoom tools can temporarily be used, for example, but then revisiting the **View** node restores the camera settings to the values in the view at the time the **Lock camera** check box was selected.

Select the **Lock rotation center** check box to lock the rotation center and turn off the automatic or manual rotation center modes. See [Moving Around and Rotating a 3D Geometry](#).

LIGHT

The **Scene light** setting is a default that always displays and is based on the geometry. The **Scene light**, **Diffuse light**, **Specular light**, and **Ambient light** check boxes are selected by default. To hide and disable all light sources, click to clear the **Scene light** check box. The **Scene Light** button (💡) is turned on or off in the **Graphics** window at the same time.

- Click to clear the **Diffuse light**, **Specular light**, and **Ambient light** check boxes as needed.
- Enter a value between 0 and 1 for the **Ambient intensity** (default value: 0.3) or use the slider to select a level. Watch the changes in the **Graphics** window at the same time to help choose a level.
- Select a **Color** from the list: **Custom**, **Black**, **Blue**, **Cyan**, **Gray**, **Green**, **Magenta**, **Red**, **White** (default), or **Yellow**. The color is only applied to ambient light. If you select **Custom**, click the **Color** button to choose a color from the **Custom color** palette.

TRANSPARENCY

Select the **Transparency** check box to turn on transparency. The **Transparency** button (▢) is activated in the **Graphics** window at the same time. Enter a value between 0 and 1 in the **Alpha** field for the alpha blending, where 0 means a fully transparent color and 1 means a fully opaque color, or use the slider to select a transparency level. Watch the changes in the **Graphics** window at the same time to help choose a level.

COLORS

Clear the **Show selection colors** check box if you do not want to include colors indicating user-defined selections.

Select the **Show material colors and texture** check box if you want to include colors and texture indicating the material used in the geometry.

Camera

Use the **Camera** node (🎥) to orient the camera view in 3D models. In the **Model Builder**, under **Definitions** click to expand the **View** node where you want to define the camera position. A **Camera** node is added by default.

Units wherever applicable (in the settings for position, target, and center of rotation, for example) follow the unit system specified in the **Root** node's settings.

CAMERA

From the **Projection** list, select **Perspective** (the default) or **Orthographic** (parallel) as needed. The perspective projection shows distant objects as smaller to provide a realistic 3D projection, whereas the orthographic projection

shows all objects using their actual size regardless of the distance. You can also control the projection using the **Orthographic Projection** button () on the **Graphics** window toolbar.

Enter a **Zoom angle** (in degrees) or use the **Zoom** buttons in the **Graphics** window toolbar.

The default setting in the **View scale** list is **None**, which makes the increments equal in all directions.

Select **Automatic** to make the geometry fill the graphics window with unequal increments. This can be useful when working with thin and slender geometries. By default, the automatic scaling is isotropic (a cube), which corresponds to **Isotropic** selected in the **Automatic** list. Select **Anisotropic** to define an anisotropic automatic scaling (a block) using different relative weights in the **x**-, **y**-, and **z**-directions, which you enter in the **x weight**, **y weight**, and **z weight** fields. If you want the view scale to update every time the view changes, select the **Automatic update** check box.

Select **Manual** to specify the view scale in the **x scale**, **y scale**, and **z scale** text fields. Equal values, such as 1, make the geometries appear with the correct aspect ratio. The default values represent the view scale of the previous setting in the **View scale** list.

POSITION

In the **Graphics** window, left-click and hold the mouse to orient the geometry on the axes, or enter **x**, **y**, and **z** coordinates.

TARGET

In the **Graphics** window, left-click and hold the mouse to orient the geometry on the axes. The corresponding coordinates are displayed in the **Settings** window under the **Position**, **Target**, and **Up Vector** sections, or enter **x**, **y**, and **z** coordinates for the camera target location.

The **Position** is the location of the camera and the **Target** default is 1 length unit in front of the camera position.

UP VECTOR

In the **Graphics** window (or other plot windows), left-click and hold the mouse to orient the geometry on the axes, or enter **x**, **y**, and **z** coordinates for the camera's up vector, which determines which direction is up in the plot window.

CENTER OF ROTATION

By default, the values in the **Center of Rotation** section define the center of the geometry in the view. To control the center of rotation explicitly, enter a center location in the **x**, **y**, and **z** fields and then click the **Update** button () at the top of the **Settings** window.

VIEW OFFSET

Right-click the mouse and move the geometry left, right, up, or down as needed. This shift operation moves the currently visible frame on the image plane. The corresponding dimensionless values that display in the **Settings** window under **View Offset** are relative to the image width and height, respectively. For example, an offset of **x** = 0.5 moves the projection 0.5 screen widths to the left. Alternatively, enter **x** and **y** values for the view offset.

The value in the **Orthographic scale** field defines the size in scene length of the viewing block along the longest side of the canvas. If the view's camera setting uses orthotropic projection, zoom in or out by increasing or decreasing the value of the orthographic scale. For a perspective projection this setting has no effect.

GRID

Select the **Manual spacing** check box and enter **x spacing**, **y spacing**, and **z spacing** values to control the grid spacing manually. Enter **Extra x**, **Extra y**, and **Extra z** values directly or click the **Range** button () as needed.

The default precision for the 3D grid axes labels is three digits. You can change the precision in [The Preferences Dialog Box](#), using the **3D axis** field under **Display format (maximum number of digits)** on the **Graphics and Plot Windows** page.

About the 3D View Light Sources and Attributes

Light sources are the **Directional Light**, **Point Light**, **Spotlight**, or **Headlight** nodes. *Light attributes* are the scene light components, which include diffuse, specular, and ambient light (see [Figure 6-17](#)). Combined, these attribute and source settings enable the software to render the 3D model to look realistic.

LIGHT ATTRIBUTES

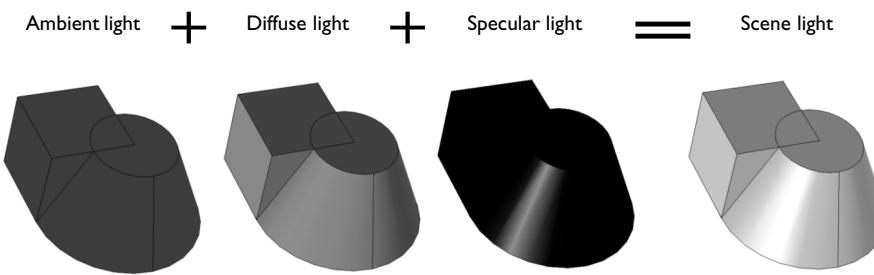

Figure 6-17: Scene light is a combination of ambient, diffuse, and specular light attributes. The default Scene light color is white and in this example the attributes display as different shades of black and gray. The Scene light is further enhanced using the various light source nodes.

Scene Light

For all geometry, scene light is applied by default and is a combination of the different light attributes. The light intensity and ambient intensity levels are also attributes of the scene light. The diffuse, specular, and ambient light attributes can be turned on or off by selecting or clearing the corresponding check boxes (see [View \(3D\)](#)). The intensity levels are adjusted either with a slider or by entering a number between 0 and 1.

Think of **Scene light** as ambient light, the base amount of light, plus specular light to add depth to curves and diffuse light to soften the lighting and add contrast. See [Figure 6-17](#) for examples of the attributes:

- **Ambient light** is the available light surrounding the geometry. By itself, ambient light makes a 3D object look like a 2D object. The addition of diffuse and specular light adds the contrast and depth needed to define 3D geometry.
- **Diffuse light** is directional and spreads out over the object, like a flashlight shining on a sphere. This generally adds contrast and depth of field to 3D objects.
- **Specular light** is directional and reflects off the surface of a sphere or curve in a geometry. It is based on the angle between the viewer and the light source.

Apply the different sources of light (**Directional Light**, **Point Light**, **Spotlight**, or **Headlight** nodes) to further enhance how the geometry displays.

LIGHT SOURCES

For 3D models, you can also add these light source nodes — **Directional Light** (), **Point Light** (), **Spotlight** (), and **Headlight** () — to adjust how the color and shading displays in the Graphics window. Each View can have a maximum of eight light sources (nodes) in any combination. See [Directional Light](#), [Point Light](#), [Spotlight](#), and [Headlight](#) below.

Each light source has a unique light marker displayed in the Graphics window. [Figure 6-19](#) shows three directional light settings and markers displayed in the Graphics window. The light markers are placed at the user-defined x , y , and z coordinates and are used to adjust the light and specular intensities on the object. You can show or hide the markers and change the color. The color of the marker corresponds to the light hitting the object. A wireframe around a light marker indicates that its node is selected in the Model Builder. When adjusting the light intensity, the light marker changes in length as the corresponding intensity is changed on the object. When adjusting the spread angle for a spotlight, the arrow increases and decreases in width as the angle value increases and decreases.

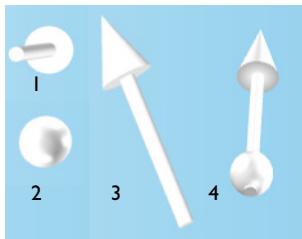

Figure 6-18: The light markers for each type of light source: (1) Headlight, (2) Point light, (3) Direction light, and (4) Spotlight.

Directional Light

By default, a **View** contains three **Directional Light** () nodes. To add additional directional lights:

- In the **Model Builder** under **Definitions** click **View**. In the **View** toolbar click **Directional Light**, or
- Right-click the **View** node and select **Directional Light**.

It is also possible to convert an added a **Headlight** node to a **Directional Light**.

Directional light represents light that falls from a direction on all objects in the scene, like sunlight where all the light rays are parallel. Directional lights therefore have no position. The direction of the light, the light and specular intensity levels, and the color can be adjusted as needed.

[Figure 6-19](#) is an example of three **Directional Light** nodes where the color is changed and the light intensity adjusted for **Directional Light 3**. The markers are labeled 1, 2, and 3 to correspond to the nodes. The **Directional Light 3** node's light intensity setting is changed from 0.24 to 1 — the change in arrow size corresponds to the increase in

light intensity. The wireframe around a light marker means that the corresponding node is selected in the **Model Builder**. Adjust the direction of the light, the light and specular intensity levels, and the color as needed.

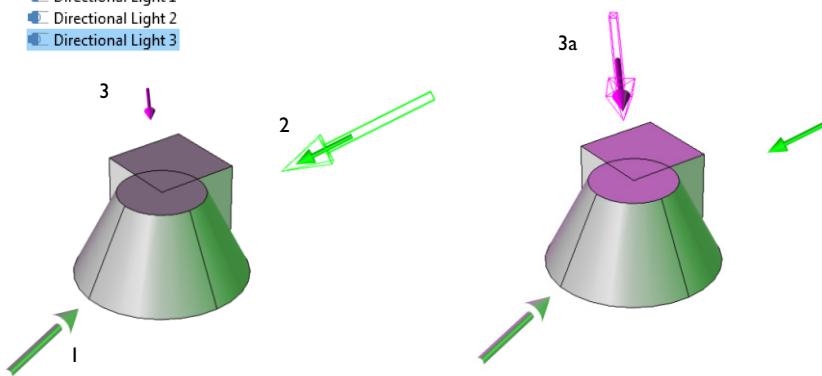

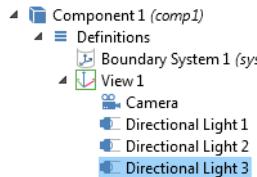

Figure 6-19: Examples of directional light markers and the location of each directional light. The markers and light can be color coded to see which areas need adjustment. The markers indicate which node is selected in the Model Builder (a wireframe around the arrow in 2 and 3a), and the level of light intensity applied (the size of the arrow; compare 3 and 3a).

DIRECTION

The **x**, **y**, and **z** coordinates define the direction in which the light falls on the objects in the scene. The arrow is a visualization of that direction with a placement that is calculated automatically depending of the scene's bounding box. The arrow points in the direction of the light.

Change the color to something other than white to observe where the light hits the object.

SETTINGS

Adjust some of the settings such as the intensity and color of the directional light.

- Enter a **Light Intensity** or use the slider to select values. Watch the changes in the **Graphics** window at the same time to help choose a level. When adjusting the light intensity, the light marker changes in length as the corresponding intensity is changed on the object.
- Enter a **Specular intensity** (the intensity of the light that reflects off the surface of the geometry and used to define spheres and curves). This setting is turned ON and OFF on the View page (the default is ON), and the levels are adjusted for each **Specular intensity** using the field or the slider to select values between 0 and 1 (default value: 1). Watch the changes in the **Graphics** window at the same time to help choose a level. See [Figure 6-17](#) for an example of specular light.
- Select a **Color: White** (default), **Custom**, **Black**, **Blue**, **Cyan**, **Green**, **Magenta**, **Red**, or **Yellow**. If you select **Custom**, click the **Color** button to choose a color from the **Custom color** palette.

- By default, the **Lock to camera coordinate system** check box is selected to make the light rotate together with the camera. Click to clear as needed; the light then follows the geometry.

To lock the camera settings, see [Camera](#).

- By default, the **Show light marker** is selected. The light marker is associated to the type of light applied to the object. See [Figure 6-18](#) for examples. Click to clear the check box as needed and remove the marker from the **Graphics** window.

Point Light

The **Point Light** () has a position and emits the light equally in all directions; it is like a light bulb. To add a **Point Light** node:

- In the **Model Builder** under **Definitions** click **View**. In the **View** toolbar click **Point Light**, or
- Right-click the **View** node and select **Point Light**.

Point light have therefore no direction. The position of the light, the light and specular intensity levels, and the color can be adjusted as needed. [Figure 6-20](#) is an example of two **Point Light** nodes added to the **View** and all other nodes disabled.

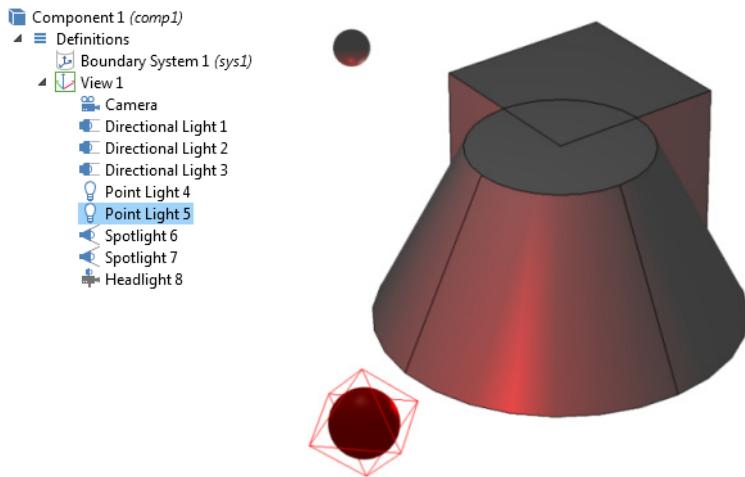

Figure 6-20: An example of two Point Light nodes added to a View. All other light nodes are disabled to show only the Point Light effects to the geometry. Point Light 5 is selected in the Model Builder as indicated by the wireframe around the light marker.

POSITION

Enter **x**, **y**, and **z** coordinates for the point light's position.

SETTINGS

Adjust some of the settings such as the intensity and color of the point light.

- Enter a **Light Intensity** or use the slider to select values. Watch the changes in the **Graphics** window at the same time to help choose a level. When adjusting the light intensity, the light marker changes in length as the corresponding intensity is changed on the object.

- Enter a **Specular intensity** (the intensity of the light that reflects off the surface of the geometry and used to define spheres and curves). This setting is turned on and off on the View page (the default is on), and the levels are adjusted for each **Specular intensity** using the field or the slider to select values between 0 and 1 (default value: 1). Watch the changes in the **Graphics** window at the same time to help choose a level. See [Figure 6-17](#) for an example of specular light.
- Select a **Color: White** (default), **Custom**, **Black**, **Blue**, **Cyan**, **Green**, **Magenta**, **Red**, or **Yellow**. If you select **Custom**, click the **Color** button to choose a color from the **Custom color** palette.
- By default, the **Lock to camera coordinate system** check box is selected to make the light rotate together with the camera. Click to clear as needed; the light then follows the geometry.

To lock the camera settings, see [Camera](#).

- By default, the **Show light marker** is selected. The light marker is associated to the type of light applied to the object. See [Figure 6-18](#) for examples. Click to clear the check box as needed and remove the marker from the **Graphics** window.

Spotlight

The **Spotlight** (💡) acts like a flashlight and has both a position and a direction. To add a **Spotlight** node:

- In the **Model Builder**, under **Definitions** click **View**. In the **View** toolbar, click **Spotlight**, or
- Right-click the **View** node and select **Spotlight**.

[Figure 6-21](#) is an example of two **Spotlight** nodes added to a **View** with all other nodes disabled. The position and direction of the light, the light and specular intensity levels, and the color can be adjusted as needed. In addition, the spread angle can be adjusted as shown in the figure. The width of the light marker corresponds to the spread angle.

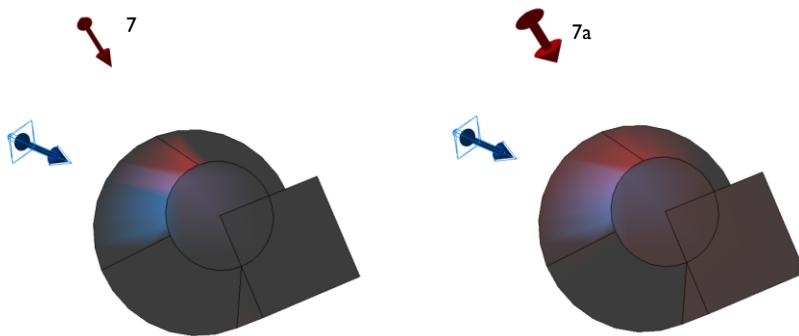

Figure 6-21: Two Spotlight nodes displayed with all other nodes disabled showing where the Spotlight is focused. When the spread angle is changed from 20 to 100 for Spotlight 7 (as indicated by the change in marker width between 7 and 7a), a corresponding change is made to the model.

POSITION

Enter **x**, **y**, and **z** coordinates for the position of the spotlight.

DIRECTION

The **x**, **y**, and **z** coordinates define the direction in which the spotlight falls on the objects in the scene. The arrow points in the direction of the light.

Change the color to something other than white to observe where the light hits the object.

SETTINGS

Adjust some of the settings such as the spread, intensity, and color of the spotlight.

- Enter a **Spread angle** (in degrees). Also watch the changes in the **Graphics** window at the same time to help choose an angle. When adjusting the spread angle, the arrow increases and decreases in width as the angle value increases and decreases. The default is 20 degrees. See [Figure 6-21](#) for an example.
 - Enter a **Light Intensity** or use the slider to select values. Watch the changes in the **Graphics** window at the same time to help choose a level. The light marker's length changes as the corresponding light intensity changes.
 - Enter a **Specular intensity** (the intensity of the light that reflects off the surface of the geometry and used to define spheres and curves). You can turn specular light on and off in the **Settings** window for **View** (default: on), and the levels are adjusted for each **Specular intensity** using the field or the slider to select values between 0 and 1 (default value: 1). Watch the changes in the **Graphics** window at the same time to help choose a level. See [Figure 6-17](#) for an example of specular light.
 - Select a **Color: White** (default), **Custom**, **Black**, **Blue**, **Cyan**, **Green**, **Magenta**, **Red**, or **Yellow**. If you select **Custom**, click the **Color** button to choose a color from the **Custom color** palette.
 - By default, the **Lock to camera coordinate system** check box is selected to make the light rotate together with the camera. Click to clear as needed; the light then follows the geometry.
-

To lock the camera settings, see [Camera](#).

- By default, the **Show light marker** is selected. The light marker is associated to the type of light applied to the object. See [Figure 6-18](#) for examples. Click to clear the check box as needed and remove the marker from the **Graphics** window.

Headlight

A headlight is a directional light that points to the scene from the camera position. The **Headlight** () is similar to the **Directional Light** with the only difference being that it is always locked to the camera's coordinate system and a direction pointing from the camera is used. To add a **Headlight** node:

- In the **Model Builder**, under **Definitions** click **View**. In the **View** toolbar, click **Headlight**, or
- Right-click the **View** node and select **Headlight**.

[Figure 6-22](#) is an example of one **Headlight** node added to a **View** with the **Directional Light** nodes enabled. The headlight's position and direction cannot be changed; it is based on the **Directional Light** node's (or nodes') *x*, *y*, and *z* coordinates. The light and specular intensity levels and the color can be adjusted as needed.

You can convert a headlight to a directional light by right-clicking the **Headlight** node and select **Convert to Directional Light**.

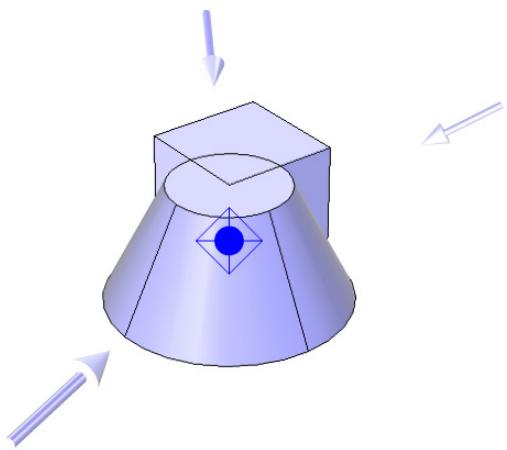

Figure 6-22: An example of a blue Headlight source with three Directional light sources set to white. If the geometry is rotated, you can adjust and view the effects of the Headlight source on the geometry based on the shades of blue and white.

SETTINGS

Adjust the settings such as the intensity and color of the headlight.

- Enter a **Light Intensity** or use the slider to select values. Watch the changes in the **Graphics** window at the same time to help choose a level. When adjusting the light intensity, the light marker changes in length as the corresponding intensity is changed on the object.
- Enter a **Specular intensity** (the intensity of the light that reflects off the surface of the geometry and used to define spheres and curves). This setting is turned ON and OFF on the View page (the default is ON), and the levels are adjusted for each **Specular intensity** using the field or the slider to select values between 0 and 1 (default value: 1). Watch the changes in the **Graphics** window at the same time to help choose a level. See [Figure 6-17](#) for an example of specular light.
- Select a **Color: White** (default), **Custom**, **Black**, **Blue**, **Cyan**, **Green**, **Magenta**, **Red**, or **Yellow**. If you select **Custom**, click the **Color** button to choose a color from the **Custom color** palette.
- By default, the **Show light marker** is selected. The light marker is associated to the type of light applied to the object. See [Figure 6-18](#) for examples. Click to clear the check box as needed and remove the marker from the **Graphics** window.

Hide for Geometry

Use the **Hide for Geometry** (🔗) feature to hide a set of geometry objects or some of their geometric entities in the created or imported geometry.

To add **Hide for Geometry** nodes:

- In the **Model Builder**, under **Definitions** click **View**. In the **View** toolbar, click **Hide**, or
- Right-click the **View** node and select **Hide Geometry Objects**.

The **Hide for Geometry** node hides geometry objects or parts of such objects and affects the view in the Geometry branch as well as the view in the Materials, physics interface, Mesh, studies, and Results branches. The **Hide for Physics** node hides geometric entities (domains, boundaries, edges, or points) in the finalized geometry and affects the view in the Materials, physics interface, Mesh, studies, and Results branches but not in the Geometry branch.

The **Settings** window for **Hide for Geometry** contains the following section:

SELECTION

Hide a set of geometry objects at a specific **Geometric entity level**: **Object** (the default), **Domain**, **Boundary**, **Edge** (3D only), or **Point**. Then select the geometry objects or some of their geometric entities in the **Graphics** window. The list under the **Geometric entity level** list contains the selected objects or entities to hide in the **Geometry** branch. For example, hide a geometry object, or hide a boundary of a 3D geometry object to make it possible to view the inside of the object. Use the **Add to Selection** (+), **Remove from Selection** (-), **Clear Selection** (Delete), and **Zoom to Selection** (Zoom) buttons as needed. Click the **Show Objects in Selection** button (Eye) at the top of the **Settings** window to show or hide the selected geometry objects or geometric entities in the **Graphics** window.

Hide for Physics

Use the **Hide for Physics** (Delete) to hide geometric entities (boundaries, for example) in the analyzed (finalized) geometry used for modeling at a specific geometric entity level for any View. Use it to hide parts of the geometry from the view in the Materials, physics interface, Mesh, studies, and Results branches. You can also use named selection to define the entities to hide.

To add **Hide for Physics** nodes:

- In the **Model Builder**, under **Definitions** click **View**. In the **View** toolbar, click **Hide**, or
- Right-click the **View** node and select **Hide for Physics**.

The **Hide for Geometry** node hides geometry objects or parts of such objects and affects the view in the Geometry branch as well.

The **Settings** window for **Hide for Physics** contains the following section:

GEOMETRIC ENTITY SELECTION

Hide a set of geometric entities at a specific **Geometric entity level**: **Domain** (the default), **Boundary**, **Edge** (3D only), or **Point**. From the **Selection** list, select **Manual** (the default) or **All domains**, **All boundaries**, **All edges** (3D only), or **All points**. The **Selection** list also contains any named selections if available for the selected geometric entity level. If **Manual** is selected, go to the **Graphics** window and select the geometric entities that you want to hide. The selected entities appear in the list under the **Selection** list. For example, hide some domains that are not of interest in the model, or some boundaries only on a specific domain to get a clearer view of some of the model. You can include the hidden entities in a plot by selecting the **Show hidden entities** check box under **Plot Settings** in the corresponding plot group's **Settings** window. Use the **Add to Selection** (+), **Remove from Selection** (-), **Clear Selection** (Delete), and **Zoom to Selection** (Zoom) buttons as needed. Click the **Show Objects in Selection** button (Eye) at the top of the **Settings** window to show or hide the selected geometry objects or geometric entities in the **Graphics** window.

Hide for Mesh Import

Use the **Hide for Mesh Import** (Delete) to hide geometric entities (boundaries, for example) in the analyzed (finalized) geometry, when based on an imported mesh, used for modeling at a specific geometric entity level for any View. It is also available from a View for a mesh part. Use it to hide parts of the geometry, created from an imported mesh or a mesh part, from the view in the Materials, physics interface, Mesh, studies, and Results branches.

To add **Hide for Mesh Import** nodes:

- In the **Model Builder**, under **Definitions** click **View**. In the **View** toolbar, click **Hide for Mesh Import**, or
- Right-click the **View** node and select **Hide for Mesh Import**.

The **Hide for Mesh Import** node is available if you have imported a mesh as an **Import** node under **Mesh** and use as the model geometry.

The **Settings** window for **Hide for Mesh Import** contains the following section:

GEOMETRIC ENTITY SELECTION

Hide a set of geometric entities at a specific **Geometric entity level**: **Domain** (the default), **Boundary**, **Edge** (3D only), or **Point**. From the **Selection** list, select **Manual** (the default) or **All domains**, **All boundaries**, **All edges** (3D only), or **All points**. If **Manual** is selected, go to the **Graphics** window and select the geometric entities that you want to hide. The selected entities appear in the list under the **Selection** list. For example, hide some domains that are not of interest in the model, or some boundaries only on a specific domain to get a clearer view of some of the model. You can include the hidden entities in a plot by selecting the **Show hidden entities** check box under **Plot Settings** in the corresponding plot group's **Settings** window. Use the **Add to Selection** (+), **Remove from Selection** (-), **Clear Selection** (X), and **Zoom to Selection** (Z) buttons as needed. Click the **Show Objects in Selection** button (eye) at the top of the **Settings** window to show or hide the selected geometry objects or geometric entities in the **Graphics** window.

Geometry Modeling and CAD Tools

The CAD tools in COMSOL Multiphysics® include many geometric primitives and operations for modeling the geometry using solid modeling and boundary modeling. This chapter covers geometry modeling in 1D, 2D, and 3D with examples of solid modeling, boundary modeling, Boolean operations, and other CAD tools. In addition, it shows how to use the tools for exploring geometric properties, such as volumes and surfaces. There is also information about using external CAD data and about adding and using geometries from the Part Libraries.

In this chapter:

- [Creating a Geometry for Analysis](#)
- [Working with Geometry Sequences](#)
- [Part Libraries](#)
- [Geometric Primitives](#)
- [Geometry Operations](#)
- [Virtual Geometry and Mesh Control Operations](#)
- [Geometry Modeling Examples](#)

Creating a Geometry for Analysis

Overview of Geometry Modeling Concepts

In COMSOL Multiphysics you can use *solid modeling* or *boundary modeling* to create objects in 1D, 2D, and 3D. These can be combined in the same geometry (*hybrid modeling*).

- During solid modeling, a geometry is formed as a combination of solid objects using *Boolean operations* like union, intersection, and difference. Objects formed by combining a collection of existing solids using Boolean operations are known as *composite solid objects*.
- Boundary modeling is the process of defining a solid in terms of its boundaries — for example, using lines to create a solid hexagonal domain in 2D. You can combine such a solid with *geometric primitives* — common solid modeling shapes like blocks, cones, spheres, rectangles, and circles, which are directly available in COMSOL Multiphysics.

In 3D, you can form 3D solid objects by defining 2D solids in *work planes* and then *extrude* and *revolve* these into 3D solids. It is also possible to *embed* 2D objects into the 3D geometry.

You can also overlay additional nonsolid objects on top of solid objects to control the distribution of the mesh and to improve analysis capabilities. For example, you can add a curve object to a geometry to control the element size in the vicinity of this curve, or add a point to guarantee a mesh vertex in a specific location or to create a time-dependent or parametric-value graph at that location in the geometry.

The settings for the nodes making up a geometry sequence can be changed at any time and the whole sequence can be rerun. It is also possible to parameterize the geometry using one or more parameters that define properties of a geometric primitive, for example. The COMSOL Multiphysics software then takes the parameterization into account as part of the geometry sequence for each step in a parametric sweep. You can also insert geometry sequences from other models into your current sequence. In general, you can use an expression that contains numbers, mathematical functions, and global parameters to define the dimensions and location of the geometry objects, work planes, and other geometry nodes.

You can import 2D geometries from DXF files and 3D geometries from STL and VRML files.

See [Import](#) for details of how to import these CAD file formats.

The CAD Import Module provides an interface for the import of CAD files in Parasolid, SAT (ACIS), Inventor, Pro/E, SOLIDWORKS, STEP, and IGES formats. In addition, the CATIA V5 Import Module provides an interface for CATIA V5 files.

The optional LiveLink™ products offer bidirectional links to 3D CAD software. Using these, you can run parametric geometry sweeps driven from the COMSOL environment but operating directly on the geometries in the respective CAD package.

The *Introduction to COMSOL Multiphysics* includes a tutorial to learn how to build the busbar geometry. See the PDF-file included with COMSOL Multiphysics.

Techniques for Creating Geometries

Several techniques can ensure that a geometry results in a good mesh and gives reasonable solution times for the analysis. They include the use of symmetry and eliminating small details, gaps, holes, and singularities.

USING SYMMETRIES

Using symmetry is one of the most effective ways to reduce the size of a model. For axially symmetric geometries, a 2D axisymmetric model is sufficient. You can easily visualize the results in a full 3D geometry using a Revolution 2D data set. Other common cases of symmetry are sector symmetry and symmetry and antisymmetry planes, which can reduce the size of a 3D model.

MAKING THE GEOMETRY MATCH THE BOUNDARY CONDITIONS

Sometimes the modeling domain is unbounded or too large for successful analysis. For those cases a suitable boundary condition can replace the exterior of the domain.

It is important that the geometry is large enough to validate the boundary conditions.

For outflows in fluid-flow models, for example, the boundary should be perpendicular to the fully developed flow. Inspections and modifications of the solved model might be necessary to verify the validity of the boundary condition. Also, for some applications, infinite elements or perfectly matched layers (PMLs) are available for modeling diffusion or wave propagation in unbounded domains.

AVOIDING EXCESSIVELY SMALL DETAILS, HOLES, AND GAPS

Many geometries, especially those designed using a CAD system, contain small holes, details, and gaps. These small features can make the domain unbounded and must be removed before analysis. Small details and holes can lead to large meshes or even failure during mesh generation. Make sure the snapping feature is activated to avoid small gaps and mismatches between the geometry objects.

The CAD Import Module contains tools for automatic and interactive repair and defeaturing of 3D CAD data. For a 2D or 3D model you can also remove small details and prepare the geometry for efficient meshing using virtual geometry operations (see [Virtual Geometry Operations](#)).

AVOIDING SINGULARITIES AND DEGENERACIES IN THE GEOMETRY

A singularity in a geometry is a sharp corner or angle that can create problems during meshing and analysis. In reality, a sharp reentrant corner leads to infinite stress values in a stress analysis of a perfectly elastic material. The stress value for a sharp corner is finite in the stress analysis, but refinement of the mesh increases the stresses in the corner without limit. To avoid a singularity, round sharp corners using fillets.

A degeneracy in the geometry can occur during solid modeling. For example, fillet areas that taper to a point and the apex of a cone can become degenerate points. These degeneracies might cause problems for the mesh generator and during the analysis. A common degeneracy in the geometry occurs when a 3D solid is created (for example, a cylinder) by rotation about an axis that touches the rotation area. It is then better to create the solid object by extruding a cross section or to use geometric 3D primitives.

Associative Geometry and Selections of Geometry Objects

Associative geometry is a concept for the automatic updating of applied physical properties, such as boundary conditions and equation coefficients, under geometric transformations. Thus, once you have defined the physical properties of a model and return to the Geometry branch to modify the geometric model, COMSOL Multiphysics updates the physical properties according to the geometry modifications. The associative geometry functionality uses geometry-mapping information between the groups of geometric entities (points, edges, boundaries, and domains) in the *finalized geometry* and the corresponding groups in the geometric model.

This geometry mapping is not always without ambiguities. COMSOL Multiphysics makes some heuristic decisions when mapping the physical properties between the finalized geometry (the object on which the physical properties are imposed) and the geometric model. In some cases, the resulting updated physical properties might not be the ones that are expected.

User-defined named *selection nodes* in the geometry sequence are useful to improve associativity compared to other selection nodes (see [Creating Named Selections in the Geometry Sequence](#)). You can refer to such selections defined in following geometry nodes (for example, as input objects). This applies both to selections of resulting entities in previous geometry nodes and selections created by selection nodes.

Choosing the Right Space Dimension

Most of the problems solved with COMSOL Multiphysics are three-dimensional (3D) in the real world. In many cases it is sufficient to solve a two-dimensional (2D) or one-dimensional (1D) problem that is close, or equivalent, to the real 3D problem. 2D models are easier to modify and generally solve much faster, so modeling mistakes are easier to find when working in 2D. Once the 2D model is verified, you are in a better position to build a 3D model.

Not all physics interfaces are available in all space dimensions. See the documentation for the physics interfaces in COMSOL and its modules for the supported space dimensions.

ID MODELS

The following is a guide for some of the common approximations made for 1D models. Remember that modeling in 1D usually represents some 2D or 3D geometry under the assumption that nothing changes in the other dimensions.

Cartesian Coordinates

In a 1D model you view a single straight line that represents the only space dimension where there is spatial (or other) variation.

Axial Symmetry (Cylindrical Coordinates)

In an axially symmetric 1D model you view a straight line that represents the radial direction in an axially symmetric geometry.

2D MODELS

Cartesian Coordinate Systems

In this case you view a cross section in the xy -plane of the actual 3D geometry. The geometry is mathematically extended to infinity in both directions along the z -axis, assuming no variation along that axis. All the total flows in and out of boundaries are per unit length along the z -axis. A simplified way of looking at this is to assume that the geometry is extruded one unit length from the cross section along the z -axis. The total flow out of each boundary is then from the face created by the extruded boundary (a boundary in 2D is a line).

There are usually two approaches that lead to a 2D cross-sectional view of a model:

- When there is no variation of the solution in one particular dimension.
- When there is a problem where the influence of the finite extension in the third dimension can be neglected.

In some applications there are special 2D assumptions, such as the *plane strain* and *plane stress* conditions for 2D stress analysis in solid mechanics.

In addition to the unit-depth assumption, some physics interfaces (for solid mechanics and heat transfer, for example) provide the thickness as a user-defined property in 2D models. For heat transfer, the thickness is used when including out-of-plane heat transfer in the model.

Axial Symmetry (Cylindrical Coordinates)

If the 3D geometry can be constructed by revolving a cross section about an axis, and no variations in any variable occur when going around the axis of revolution, an axisymmetric physics interface can be used.

The spatial coordinates are called r and z , where r is the radius. The flow at the boundaries is given per unit length along the third dimension. Because this dimension is a revolution, you have to multiply all flows with αr , where α is the revolution angle (for example, 2π for a full turn). COMSOL Multiphysics provides this as an option during postprocessing.

Geometric Variables, Mesh Variables, and Variables Created by Frames

3 D MODELS

This section discusses 3D geometry modeling practices.

Although COMSOL fully supports arbitrary 3D geometries, it is important to simplify the problem. This is because 3D models easily get large and require more computer power, memory, and time to solve. The extra time spent on simplifying a problem is probably well spent when solving it.

Is it possible to solve the problem in 2D? Given that the necessary approximations are small, the solution is more accurate in 2D because a much denser mesh can be used. See [2D Models](#) if this is applicable.

Are there symmetries in the geometry and model? Many problems have planes where the solution on either side of the plane looks the same. A good way to check this is to flip the geometry around the plane by, for example, turning it upside down around the horizontal plane. You can then remove the geometry below the plane if you do not see any differences between the two cases regarding geometry, materials, and sources. Boundaries created by the cross section between the geometry and this plane need a symmetry boundary condition, which is available in all 3D physics interfaces.

Do you know the dependence in one direction so it can be replaced by an analytical function? You can use this approach either to convert 3D to 2D or to convert a layer to a boundary condition.

THE COORDINATE SYSTEMS AND THE SPACE DIMENSION

COMSOL Multiphysics uses a global Cartesian or cylindrical (axisymmetric) coordinate system as the basic coordinate system for the geometry. You select the geometry dimension and coordinate system when creating a new model. The default variable names for the spatial coordinates are x , y , and z for Cartesian coordinates and r , φ , and z for cylindrical coordinates. These coordinate variables (together with the variable t for the time in time-dependent models) make up the *independent variables* in COMSOL Multiphysics models.

The labels assigned to the coordinate system variables vary according to the space dimension:

- Models that are opened using the space dimensions 1D, 2D, and 3D use the Cartesian coordinate independent variable labels x , y (2D and 3D), and z (3D).
- In 2D axisymmetric geometries, the x -axis represents the r label, which is the radial coordinate, while the y -axis represents the z label, the height coordinate.
- In 1D axisymmetric geometries, the default radial coordinate is labeled r , and represented by the x -axis.

For axisymmetric cases the geometry model must fall in the positive half plane ($r \geq 0$).

- [Creating a New Model](#)
- [Coordinate Systems](#)
- [Cylindrical System](#)

Removing Interior Boundaries

Removing interior boundaries is good practice if the interior boundary is an effect of the geometry modeling and does not represent a border between different materials or between domains with different properties. When you remove the interior boundaries, the resulting geometry consists of fewer domains and puts fewer constraints on the mesh generation.

To remove interior boundaries, clear the **Keep interior boundaries** check box in a Boolean operations such as [Union](#) or [Compose](#).

It is sometimes useful to keep interior boundaries for controlling the mesh. In such cases, use virtual operations such as [Ignore Edges](#) and [Ignore Faces](#) but keep the original interior boundaries for mesh control. The interior boundaries are then not part of the geometry for defining physics nodes but are present during meshing to define areas where you want to use a finer mesh, for example. See [Mesh Control Entities](#) for more information.

Working with Geometry Sequences

The Geometry Nodes

Once you have added a Component, [The Geometry Node](#), representing the *geometry sequence* of the model component, is added under the Component node. Initially, a geometry sequence only contains a **Form Union** node. The Component's geometry is created by adding nodes to the sequence and building them.

- To add features to a geometry sequence, use the buttons in [The Geometry Toolbar](#) or right-click [The Geometry Node](#) in the **Model Builder** and then select one of the available options. Then see [Geometric Primitives](#), [Geometry Operations](#), and [Virtual Geometry and Mesh Control Operations](#) for descriptions of the geometry features. The tables in each section link to the individual feature **Settings** window descriptions.
- Learn about [Creating a Geometry Sequence](#) where you can use the buttons on the toolbars, right-click the **Geometry** node to add items from the context menu, copy and paste geometry features, insert an existing geometry sequence from another MPH file, or import a geometry. Sometimes [Exporting a Geometry](#) is useful.
- Once a geometry sequence is in place, you need to understand about [Editing and Building Geometry Nodes](#), [Measuring Geometry Objects](#), and [The Form Union/Assembly Node — Uniting the Geometry](#).

- [Creating a New Model](#)
- [The Component Node](#)
- [Working with Nodes in the Model Builder](#)
- [Global Definitions and Geometry Parts](#)
- [Creating Named Selections in the Geometry Sequence](#)

If you add Work Plane nodes in a 3D geometry, a [Plane Geometry](#) appears under the Work Plane node, and you can add 2D geometry objects and features under that node to create the 2D geometry sequence that defines the work plane's geometry. You can then extrude, revolve, or embed the work plane's 2D geometry in the 3D geometry. You can also use a work plane to define a coordinate system for defining a 3D geometry object's or feature's position.

The Geometry Toolbar

After a **Component** node is added to the model, the **Geometry** ribbon toolbar (Windows) or the **Geometry** contextual toolbar (macOS and Linux) is made accessible ([Geometry Toolbar](#)). Click the **Geometry** toolbar to display the options.

[Geometric Primitives](#) and [Geometry Operations](#) for example, can be added using these toolbars. You can also right-click [The Geometry Node](#) in the **Model Builder** and select any one of the available options. You can also use some drawing tools as listed in [Geometry Drawing Toolbar Buttons](#).

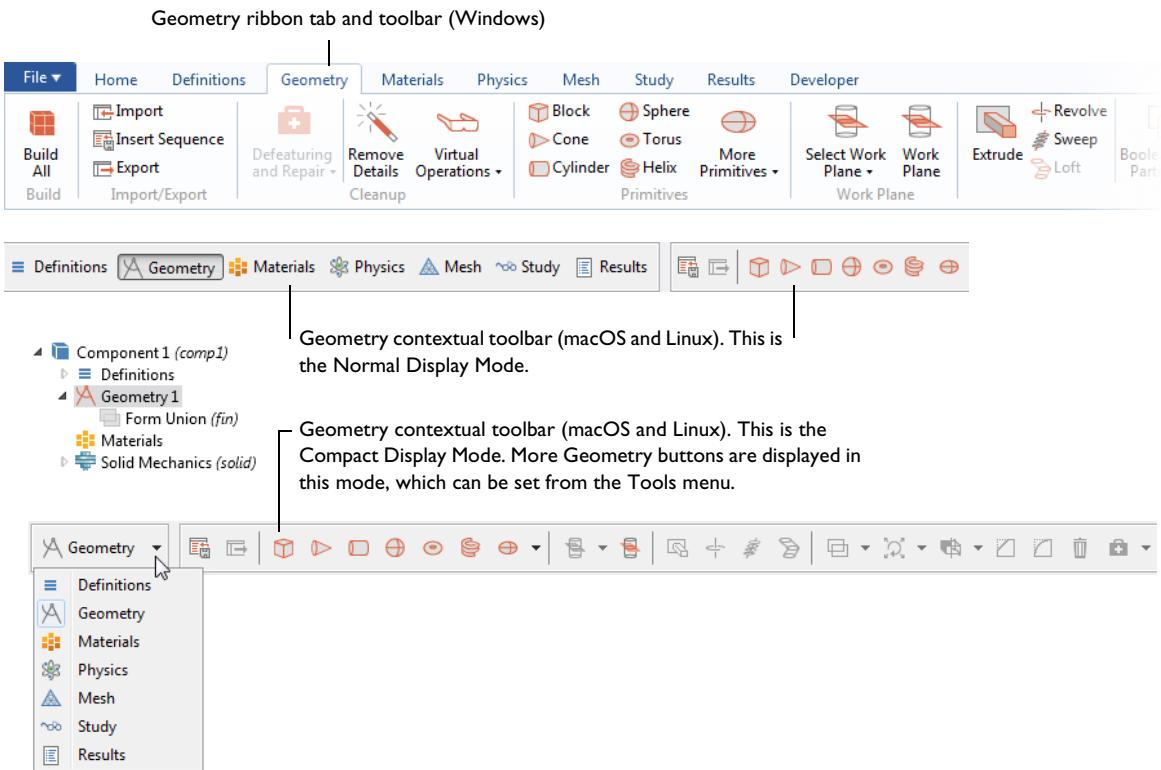

Figure 7-1: Click the Geometry ribbon toolbar (Windows users, top) or Geometry contextual toolbar (macOS and Linux users, bottom) to display the options of the Geometry toolbar. This example is the 3D toolbar. Only some of the available buttons are shown in these images, and some features are not available yet, which is indicated by a grayed out button or icon. The contextual toolbar for cross platform users can also have a Normal or Compact display mode. This changes the number of geometry buttons available.

Options become available based on where in the geometry you are working. As in [Figure 7-1](#), the **Geometry** toolbar has some options grayed out because these are not yet available. As a geometry sequence is built, and you select geometry objects in the **Graphics** window, the applicable options become available.

When one of the buttons is clicked, COMSOL Multiphysics performs the associated operation on the selected objects and creates the resulting objects, often adding a node to the geometry sequence. If you want to modify the operation, you can edit and rebuild this node. See [About Highlighted Geometric Entities in the Graphics Window](#) for details.

DRAWING GEOMETRIC PRIMITIVES IN THE GRAPHICS WINDOW

In 2D and 1D, there are buttons for drawing [Geometric Primitives](#) using the mouse. In 3D, the buttons are available to create primitives, but you cannot draw these using the mouse. See [Geometry Toolbar](#) and [Table 2-8](#) for a list of the buttons and links to the individual features.

When you move 2D geometric primitive in the Graphics window, you can use the snapping tools in the Geometry toolbar's Draw Settings section to snap to the grid and to other geometric primitives. When snapping is enabled, a red circle appears when you click and drag a geometric primitive to indicate the current snapping point for the geometric primitive that you move. If Snap to Geometry is active, then you can snap to other existing geometric primitives' corner points, centerpoints, and, for some types of geometric primitive such as rectangles, midpoints on the sides of the primitive.

DISPLAYING COORDINATES AND GEOMETRIC PRIMITIVE DIMENSIONS

For Windows users, the COMSOL Desktop displays the current x and y coordinates at the bottom of the desktop when you move the cursor in the Graphics window when working with the geometry. Also, when you interactively create 2D geometric primitives, the display shows the current dimensions for the following geometric primitives:

- Rectangle: The width and height; for example, **w=3.345, h=2.335**
- Square: The side length; for example, **s=1.353**
- Circle: The radius; for example, **r=1.352**
- Ellipse: The semiaxes; for example, **a=3.525, b=5.134**

If you do not want to display this information, you can clear the **Show mouse coordinates when drawing** check box on the **Graphics and Plot Windows** page in the **Preferences** dialog box.

Moving and Scaling 2D Objects in the Graphics Window

For 2D geometries, you can click the **Edit** button () in the **Graphics** window's toolbar to enter an Edit selection mode, where you can perform the following actions:

- Click to select; then click-and-drag to move a geometry object in the 2D geometry plane.
- Click to select; then click- and-drag using one of the small squares in the frame that surrounds the selected objects to scale it. If the scaling is isotropic so that the geometry object retains its original shape and type, the geometry object's settings show the resulting size and position. If the scaling is anisotropic (stretching a square so that it becomes a rectangle, for example), a **Scale** node appears under the geometry objects' nodes in the geometry sequence, and it contains the corresponding anisotropic scale factors.
- Alt-click to enter a mode where you can edit the geometry object by clicking-and-dragging control points in the Graphics window. Right-click to exit this mode; an **Edit Object** node then appears under the geometry objects' nodes in the geometry sequence, and it contains the properties of the edited object. See [Editing 2D Geometry Objects](#) below.

When you work in the Edit selection mode, there is no highlighting of objects when you hover over them with the mouse. Click to select a single geometry object; ctrl-click to select multiple objects. Click outside of the geometry object to deselect.

EDITING 2D GEOMETRY OBJECTS

Use the **Edit Object** () node to adjust the edges and vertices for a 2D geometry object or to add or delete edges and vertices in the object. In the **Model Builder**, right-click a 2D **Geometry** and select **Edit Object**.

The **Edit Object** function can also be started using the **Edit Object** button () in the Geometry toolbar:

- 1 In the **Model Builder** click the **Geometry** node.
- 2 Select a single geometry object in the **Graphics** window.
- 3 Click the **Edit Object** button () . The **Graphics** window displays handles for vertices and edge control points in the selected object.
- 4 Use the mouse to drag vertices and control points to new locations. The image is updated in the **Graphics** window to show the effect on the object being edited.
- 5 Right-click to exit the object editing mode and save the changes. A new **Edit Object** node is added in the **Model Builder**. Alternatively, if the object being edited is an **Edit Object** feature, the changes are incorporated in the existing feature and no new node is added in the **Model Builder**.
- 6 Click the left mouse button outside the object being edited to cancel the editing operation.

Another way to edit a geometry object, if you are in the Edit selection mode, is to hold down the Alt key and left-click on the object in the **Graphics** window. This is equivalent to selecting the object and then using the **Edit Object** toolbar button.

See [Edit Object](#) for details.

The Geometry Node

Under a **Geometry** node (A) you define and create the geometry sequence for the model component. The **Geometry** node also contains some general settings for the geometry such as the length unit.

Adding a Component Geometry

To add a new Component, which includes a Geometry node, right-click the root node of the **Model Builder**, and select **Add Component** (or use the **Model Wizard** to create a new sequence as described in [Creating a New Model](#)). A **Component** node is added to the **Model Builder** containing a **Geometry I** (if it is the first Component) feature node with the start of a geometry sequence containing only a **Form Union** node (see [Figure 7-1](#) for an example).

See [Geometric Primitives](#), [Geometry Operations](#) and [Virtual Geometry and Mesh Control Operations](#) for descriptions of the geometry features. The tables in each section link to the individual feature **Settings** window descriptions.

To add features to a geometry sequence, use the buttons in [The Geometry Toolbar](#) or right-click the **Geometry** node (A) in the **Model Builder** and then select one of the available options.

To open the **Settings** window for a geometry, click the **Geometry** node in the Model Builder and adjust the following settings sections.

UNITS

Select the **Scale values when changing units** check box to scale the values for the geometric dimensions so that the geometric objects keep their physical size. The default setting is to not scale the values when changing units; the program then interprets the values for the geometric dimensions using the new units for length and angle. The values themselves do not change.

From the **Length unit** list select the length unit to use in fields for lengths and for visualization of the geometry. You can override the unit using the unit syntax to specify the length unit (for example, 13[mm]). When solving the model, all lengths are converted to the base unit for length. If you change the unit, COMSOL Multiphysics converts all pure numeric values in fields for lengths to the new unit, if you have selected the **Scale values when changing units** check box (see above).

For information about available length units and prefixes, see [Specifying Model Equation Settings](#).

Angular Unit

From the **Angular unit** list choose to use radians or degrees as the angular unit to use in fields for angles. You can override the unit by entering, for example, 0.3[rad]. The program assumes that numeric inputs and outputs of trigonometric functions are in radians. If you change the unit, all pure numeric values in fields for angles are converted to the new unit, if you have selected the **Scale values when changing units** check box (see above).

ADVANCED

Geometry Representation (3D Only)

This list is only visible if you have a license for the CAD Import Module. The **Geometry representation** list controls which kernel (geometric modeler) that COMSOL uses to represent and operate on the geometry objects: the CAD Import Module's kernel (Parasolid) or COMSOL's own kernel.

- If you choose **CAD kernel** (requires the CAD Import Module), all objects and operations that support the CAD Import Module's kernel use it. For example, Work Plane, Extrude, and Revolve operations do not support this kernel. You need to choose the CAD kernel to use the defeaturig and repair tools, such as the Cap Faces feature, as well as to import 3D geometries using various 3D CAD file formats.
- If you choose **COMSOL kernel**, all objects are represented using COMSOL's kernel.

When you change the **Geometry representation** setting, all nodes that support the CAD kernel are marked as edited with an asterisk (*) in the upper-right corner of the node's icon. To rebuild the geometry using the new kernel, click the **Build All** button ().

If you solve a model using the CAD kernel, it is not possible to view and postprocess the solution if you open it in a COMSOL Multiphysics session where a license for the CAD Import Module is not available.

When you create a new model, its default geometry representation is controlled by the preference setting **Geometry>Geometry representation>In new models**.

When you open an existing model, you normally use the geometry representation used in the model. To always get the possibility to convert the geometry to the COMSOL kernel, change the preference setting **Geometry>Geometry representation>When opening an existing model to Convert to COMSOL kernel**.

Default Repair Tolerance

This is the default value that is used when you add a feature that has a **Repair tolerance** list (for example, Boolean operations and conversions):

- The default value in the **Default repair tolerance** list is **Automatic**, which for the COMSOL kernel is a relative repair tolerance of 10^{-6} . For the CAD kernel, the automatic setting changes the representation of the input objects so they get a common scale factor, which is the maximum of the scale factors of the input objects; if the operation fails, the automatic setting uses the COMSOL kernel instead.
- Choose **Relative** to enter a value for the **Default relative repair tolerance** field (the default is 10^{-6}). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Default absolute repair tolerance** field (the default is 10^{-6} ; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

Automatic Rebuild

The **Automatic rebuild** check box controls if the geometry sequence is automatically rebuilt when clicking on a node in the model tree outside the geometry sequence. The default value is controlled by the preference setting **Geometry>Automatic rebuild>Default in new geometries**. Select the **Automatic rebuild** check box to always rebuild the geometry, or clear it to prevent any automatic rebuilding of the geometry.

Plane Geometry

Under a **Plane Geometry** node () you define and create the geometry sequence for a work plane. The **Plane Geometry** node also contains some settings for the visualization of the work plane's geometry.

Click the **Plane Geometry** node to open the **Work Plane Modal Toolbar**.

In the settings for the 2D geometry objects under a **Plane Geometry** nodes, the **Selections of Resulting Entities** section is only applicable in the geometry sequence, and the **Show in physics** list is therefore not available.

VISUALIZATION

Select the **View work plane geometry in 3D** check box to create the work plane geometry on the work plane in a 3D view (see [Drawing on a 2D Work Plane in 3D](#)). The default setting is to display the work plane in the **Graphics** window as a separate 2D geometry.

Under **In-plane visualization of 3D geometry**, specify how to visualize 3D objects in the work plane (as blue curves and points) by selecting one or more of the following check boxes (all of them are selected by default):

- **Coincident entities (blue)** — Show edges and points (in a pure blue color) that lie in the work plane.
- **Intersection (cyan)** — Show the intersection of 3D geometry and the work plane (in cyan).
- **Projection (light blue)** — Show the projection of all edges and points onto the work plane (in light blue).

Geometry objects created in the work plane's plane geometry (and are embedded in the 3D geometry) are not visualized using blue curves or points.

To update the visualization, click the **Build Preceding 3D State** button to show the effect of the 3D state preceding this work plane. Then, any in-plane visualization of other 3D objects, built using an extrusion from the work plane, for example, that appear below the work plane no longer appears.

Creating a Geometry Sequence

There are a variety of ways to add and build geometry nodes: use the buttons on the toolbars, right-click the Geometry node to add items from the context menu, copy and paste geometry features, insert an existing geometry sequence from another MPH file, or import a geometry.

The *Introduction to COMSOL Multiphysics* includes a tutorial to learn how to build the busbar geometry. See *Appendix A — Building a Geometry* in that book or the printed copy included with COMSOL Multiphysics.

USING THE TOOLBARS AND CONTEXT MENUS

Use the buttons in [The Geometry Toolbar](#). The buttons are available for almost all drawing primitives (in 2D/1D) as well as operations and conversions acting on geometry objects.

You can also select objects or geometric entities in the **Graphics** window and then click a button or choose a context menu item. The selected objects/entities are then an input to the created geometry operation feature. To access all the features from the context menu, right-click [The Geometry Node](#) in the Model Builder and then select one of the available options.

However the geometry is added to the sequence, define the node properties in the **Settings** window. In numerical fields you can enter expressions that contain parameters defined in **Parameters** under **Global Definitions** in the Model Tree to parameterize the geometry. Click the **Build Selected** button () in the **Settings** window to see the geometry objects that result.

COPYING AND PASTING GEOMETRY OBJECTS

When using the copy/paste functionality, the copy initially contains the same data as the copied node, but there is no future connection between the two nodes. For example, if the original node is changed, it has no effect on the second node that was copied. To keep a link between nodes, use the Transforms [Copy](#) feature instead.

With the standard copy and paste method, a copy of the geometry object (a rectangle or sphere, for example) is inserted into the same geometry sequence, or another geometry sequence in the same Component, and is added after the current feature of the selected geometry sequence. The copy feature can also be used for [Work Plane](#) geometry sequences.

The copied object must be pasted under a Component with the same space dimension. For example, a [Sphere](#) can only be pasted into a 3D Component model.

[Copying, Pasting, and Duplicating Nodes](#)

INSERTING A SEQUENCE

To insert a geometry sequence from an MPH-file:

- In the **Geometry** toolbar, click **Insert Sequence** (), or
- Right-click the **Geometry** node and select **Insert Sequence** () from the context menu.

Then browse to a filename and click **Open**. The file is scanned for geometry sequences having the right space dimension. If there is just one such sequence, its nodes are inserted into the geometry sequence after the current node. If the file contains more than one such sequence, a dialog box opens. Select the geometry sequence from the list of available sequences. Finally click **OK**. The nodes in the selected sequence are inserted into the geometry sequence after the current node.

If the geometry sequence contains references to user-defined functions or parameters, those functions and parameters are also inserted in the model under **Global Definitions**, or in case of nonglobal functions, under **Definitions** in the same Component the geometry sequence is located.

Functions and parameters are inserted even if a function or parameter with the same name already exists in the model. You have to manually resolve any conflicts before the geometry sequence can be built.

IMPORTING A GEOMETRY

To import an existing geometry:

- In the **Geometry** toolbar, click **Import** (, or
- Right-click the **Geometry** node and select **Import** () from the context menu.

Then in the **Settings** window for **Import** click **Browse**. Navigate to the geometry file and double-click it. Then click **Import**.

If the geometry import fails to analyze the face topology (for a geometry based on mesh, for example), **Error** nodes () appear under the **Import** node. If the **Error** node contains details with coordinates for the location where it failed to analyze the topology, the Graphics window indicates that location using red circles. Click the **Center at Coordinates** button to center the camera so that you can zoom into that location by clicking the **Zoom In** button () one or more times.

You could also export an existing geometry from another model and then import it. See [Exporting a Geometry](#) for information.

For example, in the COMSOL installation directory navigate to the folder `applications/COMSOL_Multiphysics/Tutorials` and double-click `virtualgeom_demo_2.mphbin`.

The location of the file varies based on the installation. For example, if the installation is on your hard drive, the file path might be similar to
`C:\Program Files\COMSOL\COMSOL54\Multiphysics\applications` (in Windows).

- [Import](#)
- [Exporting a Geometry](#)

Editing and Building Geometry Nodes

THE CURRENT NODE IN GEOMETRY SEQUENCES

Once a geometry node is added, it is inserted in the sequence after the *current node*. To indicate the current node, it displays with a quadratic frame around its icon. When you have added a node, it becomes the current node, but COMSOL Multiphysics does not build it automatically. If you select a node and build it, this node becomes current. The frame is green () to show that the current node is built. If the current node needs to be rebuilt, the frame is yellow (). See [Dynamic Nodes in the Model Builder](#) for examples that show these icon additions for visual feedback about a node's status.

Adding a Node at an Arbitrary Position in a Sequence

To add a node after an existing node, first select the existing node and then click **Build Selected** (), or right-click the existing node and select **Build Selected**. The selected node then becomes current. Then add the new node.

To add a node before an existing node, first select the existing node, right-click the existing node, and select **Build Preceding** () (or press F6). Then add the node.

EDITING A NODE

To edit a node, select it in the model tree and make changes in the **Settings** window. Nodes that you have edited display with an asterisk (*) at the upper-right corner of their icons in the **Model Builder** window. Nodes that depend on the edited node display with a yellow triangle at the lower-right corner of the node's icon to indicate that they need to be rebuilt. To see the result of your edits in the **Graphics** window, you need to build the node. You can do this in two ways:

- Click the **Build Selected** button () in the **Settings** window, or right-click the node in the tree and select **Build Selected**. This builds all nodes (if needed) from the first up to the selected node.

- Click the **Build All Objects** button () in the **Settings** window. This builds all nodes in the geometry sequence above the **Form Union/Assembly** node (if needed).
- Click the **Build All** button () in the **Settings** window or the toolbar, or right-click the **Geometry** node in the tree and select **Build All**. This builds all nodes in the geometry sequence (if needed).

HIGHLIGHTING THE RESULTING GEOMETRY OBJECTS

To highlight the result of a node in the geometry sequence, click the **Highlight Result** button () in the **Settings** window. If that button is pressed, the resulting geometry objects are highlighted using a yellow color in the **Graphics** window. Click the **Highlight Result** button () again to turn off the highlighting. The state of the button is common for all nodes in the geometry sequence.

AUTOMATIC BUILDING OF GEOMETRY NODES

In some situations, COMSOL Multiphysics builds geometry nodes directly, such as when you:

- Add a node, the software builds the current node (and all its preceding nodes) before showing the **Settings** window for the new node.
- Generate a mesh or solve the model, the software builds the finalized geometry; that is, it builds all nodes if needed.
- Select a node that uses the finalized geometry, like physics nodes and mesh nodes, the software builds the finalized geometry if **Automatic rebuild** is selected in the geometry node settings.
- Open a CAD Defeaturing tools settings, the software builds the current node (and all its preceding nodes).

DELETING NODES

- To delete selected nodes, right-click the nodes and select **Delete** () or press Del (the Delete key). Confirm the deletion of nodes for it to take effect.
- To delete a geometry right-click the **Geometry** node in the **Model Builder** and select **Delete Sequence** ().
- To delete geometry objects or entities, in the **Model Builder**, right-click **Geometry** and select **Delete Entities** (). Or select objects in the **Graphics** window, and press Del (the Delete key) or click the **Delete** button () in the **Graphics** toolbar.

If you use the Delete key or the **Delete** button to delete objects, COMSOL Multiphysics deletes the selected objects that correspond to primitive features by deleting their nodes from the geometry sequence. If you delete objects that do not correspond to primitive features or if you delete geometric entities, a **Delete Entities** node appears in the sequence.

Exporting a Geometry

You can export geometry objects to a COMSOL binary file (**.mphbin**) or text file (**.mphtxt**).

2D geometry objects can also be exported to a DXF file.

3D geometry objects can also be exported to an STL file. If you have a license for the CAD Import Module, the Design Module, or a LiveLink product for CAD software, 3D geometry objects can also be exported to Parasolid files (**.x_t**, or **.x_b**) or ACIS files (**.sat**, or **.sab**).

To export an existing geometry to file:

- In the **Geometry** toolbar, click **Export** (), or
- Right-click the **Geometry** node and select **Export** () from the context menu.

Then, in the **Export** window, select a file type among the available formats in the **File type** list and enter a filename including the path in the **Filename** field (or click **Browse** to specify the filename).

For STL file export you can select objects, domains, or boundaries to export. For the other file types you select the objects to export by first clicking the **Export selected objects** button and then adding the objects to export to the **Selected object** list, or click the **Export Entire Finalized Geometry** button to export the result of the finalize operation.

For a geometry part and for a Plane Geometry of a work plane, the **Export Entire Finalized Geometry** option does not exist, so that button and the **Export selected objects** button are not available. Instead, just add objects to export to the **Selected object** list.

Click **Export** to export the selected geometry to the specified file. A confirmation message appears in [The Messages Window](#).

The **.mphbin** and **.mphtxt** formats do not contain unit information. When the exported file is imported into a geometry with a different length unit, you can use a [Scale](#) feature to scale the imported objects to the correct size.

To export a geometry to use in an earlier version of COMSOL Multiphysics in the COMSOL format, select a version from the **Compatible with version** list.

- Also see [Import](#) for details of how to import CAD file formats.
- [Creating a Geometry Sequence](#)

Measuring Geometry Objects

To measure a set of geometric objects or entities selected in the **Graphics** window, click the **Measure** button () in the **Geometry** toolbar (this button is also available in the **Mesh** toolbar). The result appears in [The Messages Window](#):

- If objects are selected, the number of entities and objects is displayed.
- If domains are selected, the total volume/area/length and boundary area/length is displayed.
- If faces/edges are selected, the total area/length is displayed.
- If a single vertex is selected, its coordinates are displayed.
- If two vertices are selected, the distance between those vertices is displayed.

For most measured quantities, the precision is the one set in the **Output display precision** field in the **Preferences** dialog box. For straight edges and for the coordinates of and distances between vertices, the precision is at least 10 digits.

Another way to measure geometry objects, is to right-click the **Geometry** node and select **Measure** () from the context menu. This opens the **Measure** window, which has the following contents:

The **Measure** window is a tool to measure geometry objects and entities. You can, for example, measure the volume, area, or length of a selected domain, face, or edge. Also view the coordinates of a vertex, the distance between two vertices, or the number of entities and the geometry representation (requires a license for the CAD Import Module) of an object.

GEOMETRY TYPE

From the **Type of geometry** list, select to measure geometry objects (the default) or the finalized geometry.

SELECTION

From the **Geometric entity level** list, select **Object**, **Domain**, **Boundary**, **Edge**, or **Point**. Then select some objects or entities of the selected type to add to the list.

MEASUREMENTS

Under **Measurements** you find information about these objects or entities. For objects, this section contains the total number of domains, boundaries, edges, and points, and the geometry representation. For domains, boundaries, and edges, their total volume, area, or length appears. If you select a point, its coordinates are shown. If you select two points, the distance is shown.

You can add a **Mass Properties** node to define variables for mass properties such as the total volume, total mass, and the center of mass.

The Form Union/Assembly Node — Uniting the Geometry

To unite the geometry, COMSOL Multiphysics evaluates the geometry sequence from the top down. The final node in the geometry sequence (before any virtual operations, if present), the **Form Union/Assembly** node, determines how to form the geometry that is used for meshing and analysis (possibly after also applying virtual operations). There are two methods to form the geometry, which also determine the name of the node: **Form Union** or **Form Assembly** ([]). There are some differences and aspects to consider when choosing a method:

- The default method is to form a *union*. The software then forms a union from all geometry objects that the geometry sequence contains or creates. The union is divided into domains separated by boundaries according to the participating geometry objects. You can mesh the entire geometry and model the physics by assigning material properties, boundary conditions, and other data for the model. It is also possible but often not necessary to specify boundary conditions on interior boundaries between domains in the geometry. By default, COMSOL Multiphysics ensures continuity in the physics interface fields across interior boundaries. See also [Removing Interior Boundaries](#).
- The alternative method is to form an *assembly*. The software then treats the geometry as a collection of the geometry objects instead of uniting them. This means that you must use pairs to connect boundaries where a field is continuous, but it also makes it possible to use special pair conditions for applications such as contact modeling, where you can add contact pairs to model contact between geometric parts (requires the Structural Mechanics Module or the MEMS Module). Forming an assembly is also required to model geometry domains that slide or move relative to each other. By default, identity pairs are created automatically when forming an assembly. An assembly can also be useful for meshing each geometry object independently in, for example, thin and slender geometries with high aspect ratios. Another case where you need to use an assembly is when the geometry is too complex for forming a union, which might be the case when importing an assembly geometry from CAD data.

When forming a union or an assembly for axisymmetric models, COMSOL Multiphysics removes all parts of the geometry from the $r < 0$ half plane.

PHYSICS CONSIDERATIONS

The physical implication of the Form Union step is that the domains in the model cannot slide or move relative to each other. This is an appropriate default assumption for most modeling within COMSOL Multiphysics, but it is not valid when using any of the following physics interfaces:

- Solid Mechanics, when contact features are included
- Multibody Dynamics
- Rotating Machinery, Magnetic
- Rotating Machinery, Fluid Flow

When you use any of the above physics interfaces, or when you want to have a nonconforming mesh between adjacent domains, finalize the geometry with the Form Assembly setting instead.

The **Form Union/Assembly** node () ends each geometry sequence in 1D. In 2D and 3D, it is possible to add virtual operation nodes, some partitioning nodes, and selection nodes after that node. In the Model Tree, its label is **Form Union** or **Form Assembly** depending on its settings. By default, it unites all geometry objects into a single geometry object (this is the **Form Union** variant). You cannot delete or disable the **Form Union/Assembly** node. When you leave the geometry sequence to define materials or physics nodes, the **Messages** window provides information about the method (forming a union or an assembly) and about the number of geometric entities (domain, boundaries, and so on) in the geometry.

FORM UNION/ASSEMBLY

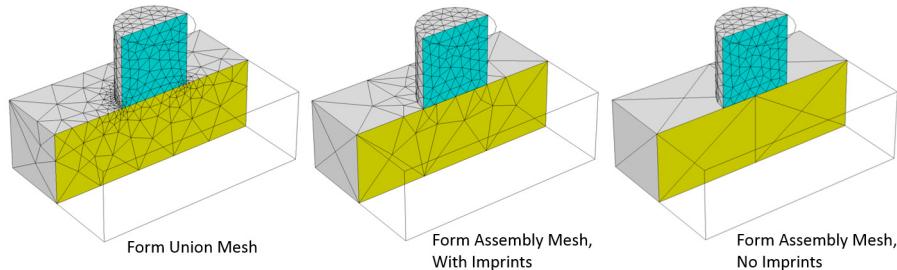

The default method, **Form a union**, forms a union of all geometry objects. Select **Form an assembly** from the **Action** list if you do not want the geometry objects to be united. The program then forms the geometry by collecting the objects in an *assembly object*. If you form an assembly, select the **Create imprints** check box to get imprints of the geometry objects that touch each other. An imprint of a usually smaller object's boundary on an adjacent larger object's boundary inserts points on the boundary in 2D and creates edges on the boundary in 3D. Creating imprints can be useful when you need identical matching meshes on both objects' boundaries or when you want to split the larger boundary so that it contains a segment or area that matches the smaller boundary. Select the **Create pairs** check box (selected by default) to generate pairs corresponding to the objects that touch each other. Select the **Split disconnected pairs** check box to generate one pair for each connected set of boundaries. Clear the **Split disconnected pairs** check box to generate one pair for each pair of objects that touch each other. From the **Pair type** list, select **Identity pair** (the default) to generate identity pairs, which makes it possible to connect the physics fields across the objects' boundaries, or **Contact pair** to generate contact pairs. Contact pairs are only useful for contact modeling in structural mechanics and require a license for the Structural Mechanics Module or the MEMS Module.

You can change the settings for the **Repair tolerance** list if you experience problems with the Form Union/Assembly operation.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

MESHING ASPECTS

The options for creating meshes depend on whether you form a union or form an assembly, with or without imprints. The following figure shows a comparison of the meshes created with Form Union, Form Assembly with imprints, and Form Assembly without imprints.

The Form Union mesh is a conforming mesh across the mating face. That is, the mesh elements on either side of the boundaries share the same nodes and faces. With such a mesh, the continuity of the fields and fluxes is naturally satisfied via the finite element method. The Form Assembly mesh makes it possible to create nonconforming meshes. The element faces at that boundary will share nodes. With imprints enabled, the element boundaries line up. The elements on either side have nonconforming nodes, but the software adds constraint equations to approximately enforce continuity of the fields and fluxes. With imprints disabled, the element boundaries between objects do not line up. The constraint equations that approximately enforce continuity of the fields and fluxes between the domains will be more approximate. The Form Union mesh will be the most accurate but require the most memory to solve. The Form Assembly without imprints will be the least accurate and require relatively less memory to solve.

In 2D and 3D, virtual operation nodes and selection nodes can appear after the **Form Union/Assembly** node.

Using Geometry Parts

If you consider the geometry sequence as a computer program, a *geometry part* corresponds to a subroutine, function, method, or procedure in a programming language. In other words, a geometry part is a geometry sequence whose input is a set of input parameters (having numerical values) and whose output is a set of geometry objects, making it possible to create instances of these parts using different input parameter values and different orientation and position in the overall geometry.

You can call the geometry part (that is, create an instance of the part) with new values of the input parameters (arguments). You can call it several times, and the calls can be nested. You can also include several variants of a part in an MPH-file, which makes it possible to choose from those part variants when loading the part.

CREATING A GEOMETRY PART

The geometry parts appear under the **Geometry Parts** node (A), located under **Global Definitions** (Globe icon) in the model tree, so they are not attached to a specific model component. To create a part, right-click the **Global Definitions** node, and then, from the **Geometry Parts** submenu, select **3D Part**, **2D Part**, or **ID Part**. If a **Geometry Parts** node (A) exists, you can also right-click it to add a **3D Part**, **2D Part**, or **ID Part**. To parameterize the geometry part you can use global parameters and input parameters (arguments), which you add in the **Part** node's **Settings** window (see [Geometry Part Settings](#)). You can also add local parameters using a **Local Parameters** subnode (see [Local Parameters](#)).

Within the part you can use parameters in expressions, just like you use global parameters in a geometry sequence. If an input parameter or a local parameter has the same name as a global parameter, the input parameter or local parameter is used; that is, the global parameter is shadowed within the part. You add geometry features to the part as usual. There is also a **View** node with view settings (see [User-Defined Views](#)) below the geometry feature nodes. When defining a geometry part, you can specify colors for the selections in the same way as for other geometry sequences. These color settings will then be transferred to the part instances selections.

LOADING GEOMETRY PARTS

You can load one or more geometry parts from a Model MPH-file, which can contain a number of parts and serve as a part library (see [Part Libraries](#)):

- In the **Geometry** ribbon toolbar, **Parts** menu, click **Load Parts** (), or
- Right-click the **Global Definitions** node, and then, from the **Geometry Parts** submenu, select **Load Parts** () (or, if it exists, right-click the global **Geometry Parts** node () and select **Load Parts** () from the context menu).

Then, in the **Load Part** window that opens, browse to a filename and click **Open**. The file is scanned for geometry parts. It is not possible to load a part that is linked into the MPH-file. Such a part should be linked directly from the MPH-file where it is defined. If there is just one linkable part, it is added under the **Geometry Parts** node. If the file contains more than one linkable parts, a **Load Part** dialog box opens. Select one or more parts from the list of available parts. Finally click **OK**. The selected parts are added under the **Geometry Parts** node. For information about the settings for these loaded geometry parts, see [Loaded Part Settings](#).

If the parts contain references to global user-defined functions or parameters, those functions and parameters are also inserted in the model under the **Global Definitions** node. If a function or parameter with the same name already exists in the model, that function or parameter is not copied from the MPH-file.

You cannot modify loaded parts, and their definitions are not displayed in the model tree. If you want to modify a loaded part or see its definitions, open the MPH-file in which the part is defined.

To update a loaded part that has been modified in the MPH-file, click the **Reload** button in the **Settings** window's **File** section. If the name or the location of the MPH-file has been changed, you can modify the path directly using the **Filename** field or set the new filename using the **Browse** button. Click the **Replace from Library** button to replace the loaded part with one that is a part in the Part Libraries.

You can call loaded parts from geometry sequences in the same way as ordinary parts.

CREATING AN INSTANCE OF A GEOMETRY PART

In a geometry sequence or part, you can create an instance of a geometry part by right-clicking the **Geometry** node and selecting a part from the **Geometry Parts** menu. This adds a **Part Instance** node (, whose purpose is to build an instance of the part with new values of its input parameters (arguments). You can also change the position and orientation of the resulting part instances. See [Part Instance](#) for details.

A **Part Instance** node can optionally make an instance of a local part instead of a part under **Global Definitions>Geometry Parts**. To use a local part, select **Local part** from the **Part** list in the **Settings** window for a **Part Instance** node. In this case, the local part appears beneath the **Part Instance** node as a **Local Part** subnode.

DEBUGGING A GEOMETRY PART

Sometimes you want to inspect what happens when you build an instance of a part. To do so, right-click the **Part Instance** node (, and select **Step Into** (). This builds all preceding features and shows a copy of the called part beneath the **Part Instance** node. The copy is identical to the part, except that the input parameters have different

values. You can now build features in the copy. You can also try out modifications in the copy. You can then apply the modifications in the part.

When you build the Part Instance, you lose the changes you have made in the copy. If you want to keep your changes, switch to using a local sequence by selecting **Local part** in the **Part** list.

If an error occurs when you build the Part Instance, a copy of the called part appears automatically so that you can locate the error.

Geometry Part Settings

Under a **Part** node or **Local Part** node you define and create a geometry sequence with geometric primitives and features as subnodes. The **Settings** window for a **Part** node is identical to the **Settings** window for a corresponding **Geometry** node of the same dimension, except that there is an **Input Parameters** section and no **Automatic rebuild** check box (see [The Geometry Node](#)). There is also a special setting for part variants in the **Advanced** section (see below).

INPUT PARAMETERS

Enter the names of the input parameters (arguments) in the **Name** column. In the **Default expression** column, enter their default values as expressions in terms of global parameters and numerical values. The corresponding values appear in the **Value** column. Optionally, enter descriptions for the input parameters in the **Description** column. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** (✖) buttons to organize the list. Click the **Save to File** button (💾) and the **Load from File** button (📁) to save and load parameters to and from a text file. Click the **Insert Expression** button (✉) or press Ctrl+Space to insert an available or applicable expression such as a global parameter.

Parameters that are used within the part but should not be specified by users of the part, should instead be entered in the **Local Parameters** node, which you can add by right-clicking the part node and choosing **Local Parameters**.

ADVANCED

Select the **Show as variant in part library** check box to create a part variant; that is, the part is one of two or more variants of the same geometry part. You can use this functionality to make it possible to choose variants of a part instead of different separate geometry parts. Parts in the same MPH-file that are not variants are not visible for users of the part library. It can be a part that creates the basic part for which the part variants provide transformation of the input parameters, for example. When you add a part from an MPH-file that includes variants, a **Select Part Variant** window appears, where you can choose the variant that you want to use.

Loaded Part Settings

A loaded **Part** node contains a link to a geometry part in another MPH-file and has no subnodes. The **Settings** window for a loaded **Part** node includes the following sections:

FILE

In the **File** section you specify the location of the part that you load:

- A **Filename** field where you specify the path and filename to the Model MPH-file with the part that you are loading. Click **Browse** to search for a Model MPH-file with at least one part on the file system. The part that you

load is displayed under **Part**. This **Filename** field is set to the Model MPH-file that you selected with the **Load Part** command.

- Click **Reload** to load the current version of the part in the other Model MPH-file if necessary.
- Click **Replace from Library** to open the **Part Libraries** window and choose a compatible geometry part that you then link to instead, replacing the current link.

PART

This section includes the label and tag of the part that you link to.

DESCRIPTION

This section contains a description of the part, if available.

THUMBNAIL

For parts loaded from a part library shipped with COMSOL Multiphysics or any of the add-on modules, or other parts that include a thumbnail image, that associated descriptive image of the part appears here.

VERSION

This section contains version information for the part at the time when it was linked in the model: a version number and the date and time for when it was last modified.

Local Parameters

You can right-click a **Part** node to add a **Local Parameters** subnode (). There can be at most one such subnode for each **Part** node. In the **Local Parameters** subnode you can add parameters that are locally available for that particular geometry part (in addition to global parameters, which are also available). The **Settings** window is identical to the one for a global **Parameters** node (see [Parameters](#)).

Part Libraries

Introduction

The **Part Libraries** contain collections of geometry parts, which serve as extended geometric primitives or parameterized geometry sequences specially created for an application area. These parts are stored as *part models*, which are COMSOL MPH files that contain only the following:

- One or several geometry parts. The first part is the *main part*, and it is the only one that the user of the part model will see. Other parts can exist for the sole purpose to be called from the main sequence.
 - Optionally, a number of global functions that are used by the part.
-

A part model does not contain materials, mesh, or physics.

Some part libraries ship with the COMSOL products, but you can also add your own part libraries. In COMSOL Multiphysics, the **Examples** folder contains two parts: **bent_pipe**, which is toroidal pipe with a wall, and **straight_pipe**, which is a straight cylindrical pipe with a wall. The input parameters make it possible to create instances of these parts with a varying inner radius and wall thickness, for example.

Using Part Libraries

THE PART LIBRARIES

The **Part Libraries** window () (Figure 7-2) contains sets of parts that you can use as custom geometric parts representing common parts or components within an application area. Some of the add-on modules include their own part libraries with parts adapted for use within their respective application areas. The location of the corresponding MPH-files is, for the Ray Optics Module, for example,

`C:\Program Files\COMSOL\COMSOL54\Multiphysics\parts\Ray_Optics_Module`

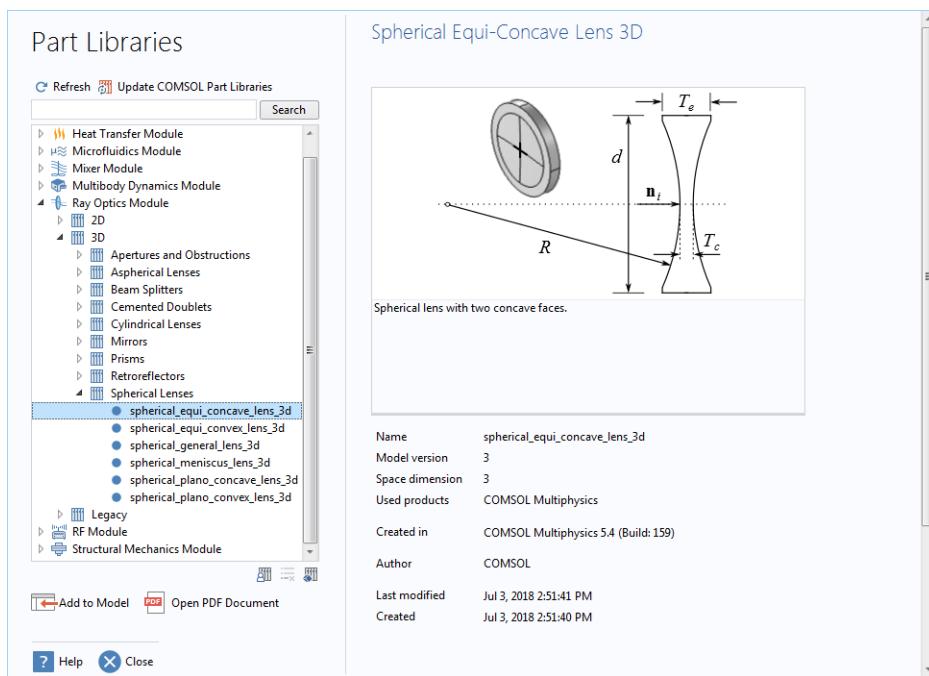

Figure 7-2: The Part Libraries window with a Spherical Equi-Concave Lens 3D part from the Ray Optics Module selected.

Browse through the **Part Libraries** tree to see what parts are available for your license. Click to highlight the part in the tree and show a schematic and some information about it to the right, or search for a specific model.

Some parts have an associated documentation file in PDF format. For those parts, you can access this document as follows:

- Click to highlight the name in the tree, then click **Open PDF Document**.
- Right-click the name, then from the context menu select **Open PDF Document**.

You can enable the **Open PDF Document** button for a user-library part by placing a PDF-file with the same name as the MPH-file in the same folder.

Opening the Part Libraries Window

You can open the **Part Libraries** window () in the following ways:

- By right-clicking the **Geometry** node () and choosing **Parts>Part Libraries**.
- By right-clicking the **Global Definitions** node () and choosing **Geometry Parts>Part Libraries**.
- By right-clicking the **Geometry Parts** node () and choosing **Part Libraries**.
- By choosing **Part Libraries** from the **Parts** menu in the **Other** section in the **Geometry** toolbar.
- By choosing **Part Libraries** from the **Windows** menu in the **Home** toolbar.
- By clicking **Choose from Library** in a **Part Instance** node's **Settings** window.
- If you have added a linked part, by clicking **Replace from Library** in a **Linked Part** node's **Settings** window.

You can set the root directory and create and remove a user-defined part library using [The Preferences Dialog Box](#) as described next.

PART LIBRARIES PREFERENCES

The following settings can be modified using the buttons at the bottom of the **Part Libraries** tree on the **Part Libraries** page in [The Preferences Dialog Box](#) and — if the **Allow managing libraries in the Part Libraries window** check box on that page is selected (the default) — also in the **Part Libraries** window itself.

Adding a User Part Library

To create a user part library, create the part under **Global Definitions>Geometry Parts** and then save the MPH file in the intended **User Part Library** folder. The parts in the user part library can then be added from that library when it is added to the **Part Libraries** window.

Click the **Add User Library** button () to add customized folders. In the **User Part Library** tree in the **Browse for Folder** dialog box, navigate to a location on your computer where you want to create a custom part library folder. Or click **Make New Folder**. Click **OK** to save the changes and exit, or **Cancel** to exit without saving.

It is not possible to add a library identical to, containing, or being contained in, any already used library.

Optionally, you can replace the standard folder icon () with custom icons of your choice that reflect the content of your library folders. To use a custom icon for a folder, create a PNG-file with an image size of 16-by-16 pixels and save it in the folder under the name folder.png.

Set the Part Library Root

Click the **Set Library Root** button () to edit or set the root folder. This redirects COMSOL Multiphysics to a different folder where customized geometry models can be stored.

In the **Part Library Root** tree in the **Browse for Folder** dialog box, navigate to the new root folder location or click **Make New Folder**. Click **OK** to save the changes and exit, or **Cancel** to exit without saving.

Remove Selected Part Library

This button is enabled after a User Part Library folder is created. Click any folder corresponding to a user part library, and then click **Remove Selected** () button to remove it from the part libraries.

OPENING AND ADDING A PART IN COMSOL MULTIPHYSICS

Once you have located the part you want to add to the geometry — for example, you used a search and it was successful (see [Searching the Part Libraries](#)), or you browsed the Part Libraries tree — then to use the part:

- Double-click the part in the tree.
- Select the part, then click () **Add to Geometry** if opened from the **Geometry** branch or **Add to Model** if opened from the **Global Definitions** branch.
- Right-click the part, then from the context menu select **Add to Geometry** if opened from the **Geometry** branch or **Add to Model** if opened from the **Global Definitions** branch.

The part then appears as a **Loaded Part** node under **Parts** () and also, if added to a geometry, in a **Part Instance** node () under the **Geometry** node in the **Component**. That **Part Instance** node calls the loaded part to create an instance of the part with the input parameters that you define under **Input Parameters** in the **Part Instance** node's **Settings** window, when you build that node or all objects in the geometry.

When you replace a part in a loaded part, you click or select **Replace in Model** instead.

The part is added to the current component (the one that appears in the Graphics window). The part can only be added if it has the same space dimension as the current component.

When using a part in 3D, you can position it by matching a work plane in the part with a work plane in your model using the settings in under **Position and Orientation of Output** in the **Part Instance** node's **Settings** window (see [Part Instance](#)).

SEARCHING THE PART LIBRARIES

You can **Search** the part libraries to find parts. For example, enter all or part of the part name or any other phrase or words and click **Search**.

By default, the search includes all words in the **Search** field.

COMSOL Multiphysics part models are named using an underscore between words (for example, *straight_pipe*) because the part model name is also the name of the corresponding MPH-file. The underscore is required to form a valid filename, so it is recommended that you, if you are not sure of the full name, enter only the first word in the **Search** field when searching for a part name.

SEARCH PARAMETERS

- To search for part models by filename only, use the prefix “@name:”, for example @name:*straight_pipe*. You can also use the wildcard character “*” at the beginning and the end of the search expression, for example @name:*pipe.
- To search for a specific built-in geometric primitive or feature, use the scoping syntax @geom:<name>. For example, enter @geom:rot to find all part models that include rotations. Note, however, that the geometry features for a geometry model are part of the implementation and not directly visible.
- To search for a phrase, enclose it in quotation marks (for example, "bent pipe"). The words can be part of the part model's name or description.

If the search does not return any results, the Part Libraries window contains the message **No Matching Model Found**. Click the **Refresh** button () under the tree to return to the root **Part Libraries** folder list.

Creating a Part

Following these steps to create a part that you can store in a part library and use as a part or specialized geometric primitive:

- 1 Start the COMSOL Desktop with a blank model.
- 2 Right-click the **Global Definitions** node, and from the **Geometry Parts** submenu, choose **3D Part**, **2D Part**, or **1D Part** to add a **Part** node for a 3D, 2D, or 1D geometry. You can also choose **Create Part** from the **Parts** menu in the **Other** section of the **Geometry** toolbar to create a **Part** node of the same space dimension as the current component in the model.
- 3 In the **Part** node's **Settings** window, give it an appropriate label. Also choose an appropriate length unit. If you want the part model to be available to users without a license for the CAD Import Module, make sure to choose **COMSOL kernel** from the **Geometry representation** list under **Advanced**.
- 4 In the **Input Parameters** table, add input parameters with appropriate names, default values, and descriptions. Use standardized input parameter names for all parts in a part library. This makes automatic matching work when a user substitutes one part for another; that is, the values of input parameters with the same name are kept. In the **Default expression** column, prefer to indicate the unit because this helps the user to understand what is expected. The default expression then also determines what unit to use if the user just enters a number when calling the part.
- 5 If you need to use local parameters (having a fixed value or depending on the input parameters), add a **Local Parameters** node under the **Part** node and add the local parameters in its **Settings** window.

- 6** Add geometry features for the part and build all of them. This geometry sequence can result in one or several geometry objects. If there is no specific reason to have several objects, make sure that there is just one object — for example, using a Union feature. Using a Union feature also has the advantage that the numbering of the entities in the resulting object is canonized (basically, the numbering increases from left to right in the x-coordinate).
- 7** Add selection features (typically Explicit Selection nodes) in the part for selections of boundaries that are relevant to users of the geometry model. Preferably, the boundary selections should be a partition of the boundaries; that is, they should not intersect and they should together cover all boundaries. In some cases, domain, edge, and point selections are also relevant. Make sure to give each selection an appropriate label. Use standardized labels in all parts in a part library (for example, Inflow, Outflow, and Wall). Doing so makes automatic matching of selections work when a user substitutes one part for another.
- 8** In 3D, add Work Plane features (with empty Plane Geometry subnodes) for important planes. Users can then use these to position the resulting objects when calling the part. Usually, you use face parallel work planes with the local coordinate system's origin at the center of the face (and outward normal vectors). You can control the position of the work plane's coordinate system in the **Local Coordinate System** section:
 - For inflow boundaries, use an inward-pointing normal vector.
 - For outflow boundaries, use an outward-pointing normal.
 - For boundaries that can be both inflow or outflow boundaries, use an outward-pointing normal.Give each work plane feature an appropriate label. Use standardized labels in all parts in a part library. Doing so makes automatic matching of work planes work when a user substitutes one part for another.
- 9** Click the **Build All** button.
- 10** Run a **Compact History** command (from the **File** menu) to save some space in the MPH-file.
- II** Set the model thumbnail image by clicking the **Set from Graphics Window** button in the root node's **Settings** window. If you want to use an image processor to, for example, add dimension arrows showing the meaning of the input parameters, then use the **Load from File** button instead to choose a file with the image to use as the thumbnail.
- I2** Open the root node's **Properties** window and set **Application version** to 1. You might also add an **Author**.
- I3** Save the model using an appropriate filename.

Geometric Primitives

The geometric primitives provide building blocks of basic geometric shapes for creating geometries in 1D, 2D, and 3D. The features in [Table 7-1](#) are also available as buttons on [The Geometry Toolbar](#), sometimes from the **More Primitives** (3D, 2D, or 1D) menu. You can combine and operate on all geometric primitives using Boolean operations and other [Geometry Operations](#).

TABLE 7-1: 1D, 2D, AND 3D GEOMETRY PRIMITIVES AND GEOMETRY TOOLBAR BUTTONS

BUTTON	NAME	SPACE DIMENSION	BUTTON	NAME	SPACE DIMENSION
	Bézier Polygon	2D, 3D		Interval	1D
	Block	3D		Line Segment	2D, 3D
	Circle	2D		Parametric Curve	2D, 3D
	Cone	3D		Parametric Surface	3D
	Cylinder	3D		Point	1D, 2D, 3D
	Eccentric Cone	3D		Polygon	2D, 3D
	Ellipse	2D		Pyramid	3D
	Ellipsoid	3D		Rectangle	2D
	Part Libraries	1D, 2D, 3D		Sphere	3D
	Helix	3D		Square	2D
	Hexahedron	3D		Tetrahedron	3D
	Interpolation Curve	2D, 3D		Torus	3D

If you want to refer to the domains, boundaries, edges, or points (geometric entities) in the Component, COMSOL Multiphysics can create selections for all geometric entities that a geometric primitive consists of. It is also possible to create selections in the geometry nodes for the resulting geometry objects from such operations. See [Creating Selections From Geometric Primitives and Operations](#). For some geometric primitives (blocks and spheres, for example) you can add layers for creating, for example, sandwich structures or layers of concentric spheres. For many properties, press **Ctrl+Space** (or **Ctrl+{/}**) to access global parameters and built-in constants that you can use, for example, to define the dimensions of a geometric primitive. Also see [Part Libraries](#) for information about geometry models that can serve as specialized geometric primitives.

The **Selections of Resulting Entities** section in the settings for 2D geometry objects under a **Plane Geometry** node in a work plane is different from the section as described below. See [Plane Geometry](#).

Bézier Polygon

A **Bézier Polygon** () consists of a sequence of connected line segments, quadratic Bézier curves (for example, circular arcs), and cubic Bézier curves. See [About Rational Bézier Curves](#) below for some information about Bézier curves in general.

To create a Bézier polygon, you can either:

- Right-click a 2D **Geometry** node and select **Bézier Polygon** ().
- For a 3D model, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Bézier Polygon**. Then enter the properties of the Bézier polygon in the **Settings** window, or
- On a 2D **Geometry** toolbar, **Draw** menu, click the **Line** (), **Quadratic** (), and **Cubic** () buttons to draw in the Graphics window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

To draw a polygon consisting of line segments or Bézier curves, first click one of the buttons. Then click the control points of the segments in the **Graphics** window. Click one point for each linear segment, two points for each quadratic segment, and three points for each cubic segment. If you want to switch segment type, click one of the buttons and then click some more control points. Close the polygon by right-clicking anywhere in the **Graphics** window. Then, a solid Bézier polygon appears, and a corresponding **Bézier Polygon** node appears in the geometry sequence. If you want to modify the polygon (for instance, change from a solid to a curve object) you can edit the **Bézier Polygon** node by clicking it to display its **Settings** window.

When you have added a node or finished drawing the Bézier polygon in the Graphics window, you can use the following sections to define it or fine tune it.

GENERAL

From the **Type** list, select **Solid**, **Closed curve**, or **Open curve** to specify if the Bézier polygon is a solid object (only available in 2D) or a closed or open curve object. If you choose **Solid** or **Closed curve**, the software automatically adds a line segment if needed to close the polygon.

When using the Geometry toolbar, the **Solid** button () is available to toggle between drawing a solid object or an outline (or curve) instead of selecting a **Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

POLYGON SEGMENTS

Define the Bézier polygon by adding curve segments to the list of segments. Choose linear segments, quadratic segments, or cubic segments. Delete segments by selecting them and clicking **Delete**. To edit a segment, select it in the list. When editing the last segment, click **Close Curve** to make the last control point coincide with the first control point of the first segment.

Linear Segments

To add a linear segment, click **Add Linear**. Specify the start of the linear segment on the first row of coordinates under **Control points**. Specify the end of the linear segment on the second row of coordinates.

Quadratic Segments

To add a quadratic segment, click **Add Quadratic**. Specify the coordinates of the three control points on rows under **Control points**. Add the weights of the control points under **Weights**. The default weights — 1, $1/(\sqrt{2})$, and 1 — correspond to a circular arc if the control points are three corners of a square.

Cubic Segments

To add a cubic segment, click **Add Cubic**. Specify the coordinates of the four control points on each row under **Control points**. Add the weights of the four control points under **Weights**. Cubic segments with self-intersections might look correct when displayed but are not handled correctly by other geometry and meshing operations.

COORDINATE SYSTEM

The coordinate system in which the segment coordinates above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the control points' location).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the Bézier polygon consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection** (2D only), **Boundary selection** (2D only), **Edge selection** (3D only), or **Point selection**. The default is **Domain selection** in 2D and **Edge selection** in 3D. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

ABOUT RATIONAL BÉZIER CURVES

A rational Bézier curve is a parameterized curve of the form

$$\mathbf{b}(t) = \frac{\sum_{i=0}^p \mathbf{b}_i w_i B_i^p(t)}{\sum_{i=0}^p w_i B_i^p(t)}, \quad 0 \leq t \leq 1$$

where the functions

$$B_i^p(t) = \binom{p}{i} t^i (1-t)^{p-i}$$

are the *Bernstein basis* functions of *degree p*; $\mathbf{b}_i = (x_1, \dots, x_n)$ are the control points of the *n*-dimensional space; and w_i are the weights, which should always be nonnegative numbers. The end-point interpolation property corresponds to $\mathbf{b}(0) = \mathbf{b}_0$ and $\mathbf{b}(1) = \mathbf{b}_p$. Another useful property of the rational Bézier curves is that the direction of the tangent vector at $t = 0$ and $t = 1$ is determined by the vectors $\mathbf{b}_1 - \mathbf{b}_0$ and $\mathbf{b}_p - \mathbf{b}_{p-1}$, respectively. That is, the curve is always tangent to the line connecting the control points \mathbf{b}_0 and \mathbf{b}_1 and the line connecting \mathbf{b}_{p-1} and \mathbf{b}_p . When joining curves at endpoints, aligning the (nonzero) tangent vectors assures tangential continuity. This technique produces visually smooth transitions between adjacent curves.

Quadratic Curves (Conic Sections)

Rational Bézier curves of degree 2 can represent all conic sections: circles, ellipses, parabolas, and hyperbolas. Elliptical or circular curve segments are often called arcs. The conic sections are also called quadric curves or *quadrics*. Because the parameter t is constrained to be in the interval $[0, 1]$, only a segment of the conic section is represented. A 2nd degree curve consists of three control points and three weights. There is a simple rule for classifying a 2nd degree curve if the endpoint weights are set to 1, only allowing the central weight w_1 to vary: if $w_0 = w_2 = 1$, then $0 < w_1 < 1$ gives ellipses, $w_1 = 1$ gives parabolas, and $w_1 > 1$ gives hyperbolas. For a fixed control polygon, at most one value of w_1 (among the ellipses generated by letting $0 < w_1 < 1$) gives a circle segment. For example, a quarter of a full circle is generated by a control polygon with a right angle and with a central weight of $1/\sqrt{2}$.

Cubic Curves

Rational Bézier curves of degree 3 (cubic curves) have more dynamic properties than conic section curves. A cubic curve has four control points and four weights, making it possible to create a self-intersecting control polygon or a zigzag control polygon. A self-intersecting polygon can give rise to a self-intersecting curve (loop). Self-intersecting curves and cusps are not supported.

A zigzag control polygon generates an S-shaped curve containing a point of inflection where the tangent line lies on both sides of the curve.

Block

To create a block (box), on the 3D **Geometry** toolbar, click **Block** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the block using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the block is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the edge lengths in the **Width**, **Depth**, and **Height** fields. With the default axis (representing the z -axis) and no rotation, the width, depth, and height correspond to the dimensions in the x -, y -, and z -directions, respectively.

POSITION

Enter the position of the block using the **x**, **y**, and **z** fields. From the **Base** list, choose **Center** if the block is centered about the position, or choose **Corner** if the block has one corner in this position.

AXIS

Specify the direction of the block's third axis — that is, the direction of the edges corresponding to the height. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector in the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the block's third axis in the **Rotation** field. When this angle is zero (the default), the block's second axis is parallel to the xy -plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system

appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the block's position).

LAYERS

Layers can be used to create sandwich primitives by adding layers on one or more sides. Specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Select the check boxes under **Layer position** to specify where to apply the layers (see the graphics to the right of the check boxes to see the definitions of the left, right, front, back, bottom, and top sides of the block). Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the block consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Circle

To create a circle or disk, you can:

- Right-click the 2D **Geometry** node and add a **Circle** node to the sequence then define it in the **Settings** window, or
- On the 2D **Geometry** toolbar **Draw** group, from the **Circle** (●) menu, select **Circle** (●) or **Circle (Corner)** (○). Then draw the circle in the Graphics window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

To draw a circle for a 2D model, click Circle or Circle (Corner). Then, click the circle's center (or one corner of the circle's bounding box) in the Graphics window. Drag the mouse to the desired position of a corner of the circle's bounding box. When you release the mouse button, a solid circle appears, and a Circle node appears in the geometry sequence.

When you have added a node or finished drawing the circle in the Graphics window, you can use the following section to define it or fine tune it.

OBJECT TYPE

From the **Type** list, select **Solid** or **Curve** to specify if the circle is a solid object (disk) or a curve object.

When using the geometry toolbar, the **Solid** button (■) is available to toggle between drawing a solid object or an outline (or curve) instead of selecting an **Object Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

SIZE AND SHAPE

Define the circle's radius in the **Radius** field. Enter a sector angle (in degree) for a circle sector in the **Sector angle** field. The default value is 360 degrees for a full circle.

POSITION

Enter the position of the circle using the **x** and **y** fields (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes). From the **Base** list, choose **Center** if the circle is centered about the position, or choose **Corner** if a surrounding box has a corner at the position.

ROTATION ANGLE

Specify the counterclockwise rotational angle about the position in the **Rotation** field. The default angle is 0 degrees.

LAYERS

Layers can be used to create sandwich primitives by adding several concentric circles. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the circle consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Cone

To create a right circular cone or cone frustum (conical frustum, truncated cone), on the 3D **Geometry** toolbar, click **Cone** (). By adding a **Cone** feature you can create the part of a cone contained between two circular bases without going through an apex. You can also right-click the **Geometry** node to add this node from the context menu. Enter the properties of the cone using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the cone is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the size and shape of the cone in the **Bottom radius**, **Height**, **Specify top size using**, and **Top radius** or **Semiangle** fields.

From the **Specify top size using** list select **Radius** (the default setting) to specify the cone top size using the **Top radius** field. The top radius must be a positive value or 0 for a cone with a sharp apex. Alternatively, from the **Specify top size using** list select **Angle** to specify the cone top size using the **Semiangle** field. The semiangle is the angle a cone

makes with the vertical axis. The default semiangle is roughly 26.565 degrees (that is, $\arctan(1/2)$), which for the default cone with a bottom radius and height of 1 makes the radius of the top base 0.5. For the default radius and height the maximum semiangle is 45 degrees (for a cone with a sharp apex). The maximum semiangle depends on the values for the radius and height. The semiangle must be larger than -90 degrees. Setting the semiangle to 0 makes the cone into a cylinder.

POSITION

Enter the position of the cone using the **x**, **y**, and **z** fields. This is the center of the bottom circle.

AXIS

Specify the direction of the cone's axis. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero (the default), the second axis of the cone's local coordinate system is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the cone's position).

LAYERS

Layers can be used to create sandwich primitives by adding layers to one or more sides of the cone. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Select the check boxes to specify where to apply the layers. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the cone consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Cylinder

To create a solid or hollow (surface) cylinder, in the **Geometry** toolbar, click **Cylinder** (). The cylinder is a right circular cylinder — that is, a cylinder that has circles as bases aligned one directly above the other. You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the cylinder using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the cylinder is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the size and shape of the cylinder in the **Radius** and **Height** fields.

POSITION

Enter the position of the cylinder using the **x**, **y**, and **z** fields. This is the center of the bottom circle.

AXIS

Specify the direction of the cylinder's axis. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero (the default), the second axis of the cylinder's local coordinate system is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the cylinder's position).

LAYERS

Layers can be used to create sandwich primitives by adding layers on one or more sides. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Select the check boxes to specify where to apply the layers. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the cylinder consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Eccentric Cone

To create an eccentric (oblique) cone or cone frustum with an elliptic base, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Eccentric Cone** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the eccentric cone using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the eccentric cone is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the size and shape of the eccentric cone in the **a-semiaxis**, **b-semiaxis**, **Height**, **Ratio**, **Top displacement 1**, and **Top displacement 2** fields. The bottom of the cone is an ellipse with semiaxes given in the **a-semiaxis** and **b-semiaxis** fields. The **Height** field determines the height of the cone frustum. The **Ratio** field controls the ratio between the perimeters of the top and bottom ellipses. To get an oblique cone, use the **Top displacement** fields to specify the displacement of the top ellipse's center relative to the bottom ellipse's center, in the cone's local coordinate system.

POSITION

Enter the position of the eccentric cone using the **x**, **y**, and **z** fields. This is the center of the bottom ellipse.

AXIS

Specify the direction of the third axis of the cone's local coordinate system — that is, the normal to the base ellipse. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero (the default), the second axis of the cone's local coordinate system is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the cone's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the eccentric cone consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available

outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Ellipse

To create a ellipse, you can:

- Right-click the **Geometry** node and add an **Ellipse** node to the sequence then define it in the **Settings** window, or
- On the 2D **Geometry** toolbar **Draw** group, from the **Circle** () menu, select **Ellipse** () or **Ellipse (Corner)** (). Then draw the ellipse in the Graphics window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

To draw an ellipse for a 2D model, click Ellipse or Ellipse (Corner). Then, click the ellipse's center (or one corner of the ellipse's bounding box) in the Graphics window. Drag the mouse to the desired position of a corner of the ellipse's bounding box. When you release the mouse button, a solid ellipse appears, and an Ellipse node appears in the geometry sequence.

When you have added a node or finished drawing the ellipse in the Graphics window, you can use the following section to define it or fine tune it:

OBJECT TYPE

From the **Type** list, select **Solid** or **Curve** to specify if the ellipse is a solid object or a curve object.

When using the geometry toolbar, the **Solid** button () is available to toggle between drawing a solid object or an outline (or curve) instead of selecting an **Object Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

SIZE AND SHAPE

Define the ellipse's semiaxes in the **a-semiaxis** and **b-semiaxis** fields. Enter a sector angle (in degree) for an ellipse sector in the **Sector angle** field. The default value is 360 degrees for a full ellipse.

POSITION

Enter the position of the ellipse using the **x** and **y** fields (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes). From the **Base** list, choose **Center** if the ellipse is centered about the position, or choose **Corner** if a surrounding box has one corner at the position.

ROTATION ANGLE

Specify the counterclockwise rotational angle about the base point in the **Rotation** field. The default angle is 0 degrees.

LAYERS

Layers can be used to create sandwich primitives by adding several concentric ellipses. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the ellipse consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Ellipsoid

To create an ellipsoid, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Ellipsoid** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the ellipsoid using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the ellipsoid is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the semiaxes of the ellipsoid in the **a-semiaxis**, **b-semiaxis**, and **c-semiaxis** fields.

POSITION

Enter the position of the ellipsoid's center using the **x**, **y**, and **z** fields.

AXIS

Specify the direction of the ellipsoid's third axis — that is, the principal axis corresponding to **c-semiaxis**. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector in the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the ellipsoid's third axis in the **Rotation** field. When this angle is zero (the default), the ellipsoid's second axis is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the ellipsoid's position).

LAYERS

Layers can be used to create sandwich primitives by adding several concentric ellipsoids. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the ellipsoid consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Helix

To create a helix (coil) with a circular cross section, in the **Geometry** toolbar click **Helix** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the helix using the sections in the **Settings** window.

To create a helix with a noncircular cross section, define the cross section using a work plane. Define the helix centerpoint as a 3D curve using a **Helix** node with a minor radius = 0 or a **Parametric Curve** node, and then use a **Sweep** node to sweep the cross section from the work plane along the curve to create the helix.

OBJECT TYPE

From the **Type** list, select **Solid** (the default) to create a solid helix, or select **Surface** to create a hollow helix that consists of surfaces only.

SIZE AND SHAPE

This section contains a number of properties that determine the size and shape of the helix.

The **Number of turns** field contains a positive number. The default value is 3 turns.

There are two radii:

- The **Major radius** (SI unit: m) field is the radius from the center of the helix (the default is 1 m).
- The **Minor radius** field (SI unit: m) is the radius of the cross section (the default is 0.1 m). The **Minor radius** can be zero, in which case a curve object is created. You can use this together with the **Sweep** feature to create helices with noncircular cross sections.

There are two pitches:

- The **Axial pitch** field (SI unit: m) determines the axial distance between similar positions on two consecutive turns of the helix (the default is 0.3 m).
- The **Radial pitch** field (SI unit: m) determines the radial distance between similar positions on two consecutive turns of the helix (the default is 0, which means that each turn has the same radius).

Select **Right handed** or **Left handed** from the **Chirality** list. The *chirality* or handedness of the helix can be either right handed (the default) or left handed. For a right handed helix, a clockwise screwing motion moves the helix away from the observer; for a left handed helix, a clockwise screwing motion moves it toward the observer.

From the **End caps** list, select an option to create the end caps of the helix:

- Select **Parallel to axis** (the default) to create end caps that are parallel to the helix axis.
- Select **Perpendicular to axis** to create end caps that are perpendicular to the helix axis.
- Select **Parallel to spine** to create end caps that are parallel to the spine of the helix.

The **Parallel to axis** and **Perpendicular to axis** options modify the helix in the vicinity of the end caps. They only give a valid geometry if the axial pitch is relatively small or large, respectively.

POSITION

This is the center position for the starting turn of the helix. Enter the coordinates in the **x**, **y**, and **z** fields. The default position is the origin.

AXIS

Select the **Axis type: x-axis, y-axis, z-axis, Cartesian, or Spherical**.

- Select **x-axis**, **y-axis**, or **z-axis** (the default) to define the axis direction parallel to one of the coordinate axes.
- Select **Cartesian** to define the axis direction using Cartesian coordinates in the **x**, **y**, and **z** fields. The default axis is in the *z*-direction (0, 0, 1).
- Select **Spherical** to define the axis direction using spherical coordinates θ and ϕ (angles of inclination and azimuth, respectively) in the **theta** and **phi** fields. The default angles are 0.

ROTATION ANGLE

Rotate the helix around its axis by entering an angle in the **Rotation** field. The default value is 0 degrees.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the position of the helix).

ADVANCED SETTINGS

By default, the **Twist compensation** check box is selected, which prevents the twisting that would otherwise occur due to nonzero torsion for curves that do not belong to a fixed plane. Twist compensation rotates the base circle during the sweep along the helix curve by an amount equal to the integral of the curve torsion.

Twist compensation affects the position of the vertices on the top side of the helix. Clear the **Twist compensation** check box to turn it off. See [Figure 7-3](#) below.

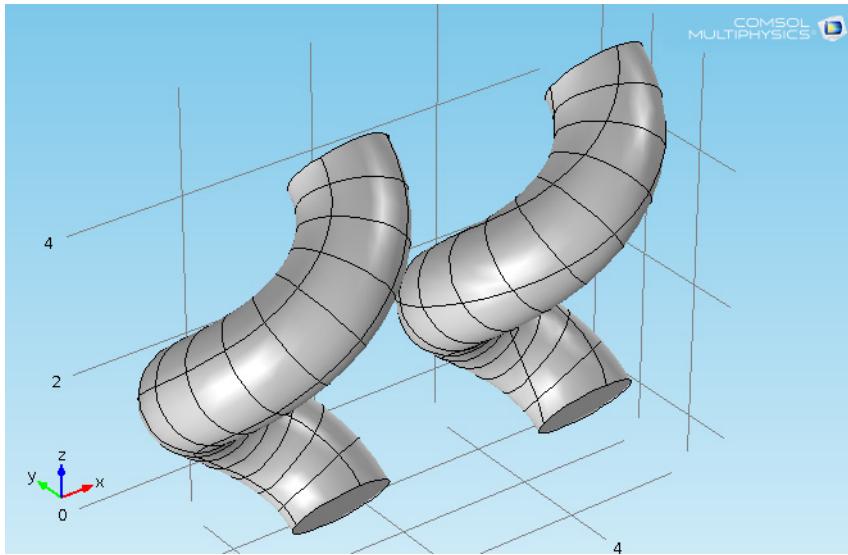

Figure 7-3: The helix on the left has twist compensation (the default). For the helix on the right, twist compensation has been turned off.

From the **Geometry representation** list, select **Spline** (the default) to represent the helix using splines, or **Bézier**, to represent the helix using Bézier curves. The difference is that using Bézier curves, the intersections between the surfaces that form the helix are visible edges, whereas they are hidden when using splines.

The value in the **Relative tolerance** field is a relative tolerance that controls the accuracy of the geometric representation of the helix. The geometric representation is an approximation, which is necessary because it is not possible to exactly represent a helix using NURBS (nonuniform rational basis splines). The default value is 10^{-4} (or 0.01%).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the helix consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Hexahedron

To create a hexahedron bounded by bilinear faces, in the **Geometry** toolbar, click **More Primitives>Hexahedron** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the hexahedron using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the hexahedron is a solid object or a (hollow) surface object.

VERTICES

Define the position, size, and shape of the hexahedron by specifying the coordinates of its vertices. Vertices 1–4 are the vertices of the bottom face in clockwise order. Vertices 5–8 are the vertices of the top face in clockwise order.

COORDINATE SYSTEM

The coordinate system in which the coordinates of the vertices above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the hexahedron's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the hexahedron consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Interpolation Curve

An interpolation curve consists of a curve that interpolates or approximates a sequence of points. To create an interpolation curve, in the **Geometry** toolbar, from the **More Primitives** (3D  or 2D ) menu, select **Interpolation Curve** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the interpolation curve using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid**, **Closed curve**, or **Open curve** to specify if the interpolation curve is a solid object (only available in 2D) or a closed or open curve object. If **Solid** or **Closed curve** is selected, a point is automatically added if needed to close the curve, and the curve has continuous first and second derivatives everywhere.

INTERPOLATION POINTS

From the **Data source** list, select **Table** to specify the points to interpolate in a table in the **Settings** window. This is the default data source. You can move rows up and down in the table, remove a row from the table, and clear the table using the buttons underneath the table. You can also load table data from file and save the table data to a file.

From the **Data source** list, select **Vectors** to specify the points to interpolate as vectors (lists) in the fields **x**, **y**, and (3D only) **z**; **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. Each field can contain a list of numbers or expressions containing parameters, separated with commas or spaces. Click the **Range** button () to use the **Range** dialog box for specifying the vector of values for each coordinate.

From the **Data source** list, select **File** to read the points to interpolate from a text file. Specify the filename in the **Filename** field or click the **Browse** button. If **Data format** is **Spreadsheet**, the file must be a text file with the number of columns equal to the dimension of the geometry sequence, and one row for each data point. The columns can be separated by a space, tab, comma, or semicolon character. If **Data format** is **Sectionwise**, the file must be in the sectionwise COMSOL Multiphysics postprocessing data format (see [About the Sectionwise Data Format for Data Export](#)). The entries in the file should be numerical. In general, nonnumerical tokens and header lines are ignored. Click the **Import to Table** button to copy the file contents into the data point table and change the **Data source** to **Table**.

If **Data source** is **File**, changes in the file do not automatically cause the interpolation curve feature to be rebuilt. To rebuild the feature after a change in the file, click the **Rebuild with Current File** button.

In the **Relative tolerance** field, enter the maximum allowed distance between the generated curve and the sequence of points. The default value 0 implies that the curve interpolates all points. If the relative tolerance is larger than 0, the curve does not necessarily interpolate all points, but the first and last points are interpolated.

Curves with self intersections might look correct when displayed but are not handled correctly by other geometry and meshing operations. This also applies if two different parts of the curve touch, even if they do not intersect.

END CONDITIONS

This section is visible only when the object type is **Open curve** and the **Relative tolerance** is 0. Also, this section is not visible if **Data source** is **File** and **Data format** is **Sectionwise**.

From the **Condition at starting point** list, choose **Zero curvature** (the default) or choose **Tangent direction** to specify a tangent in the **x**, **y**, and **z** (3D) fields.

From the **Condition at endpoint** list, choose **Zero curvature** (the default) or choose **Tangent direction** to specify a tangent in the **x**, **y**, and **z** (3D) fields.

For the end conditions, the zero curvature is also called *natural spline*. The tangent direction is also called a *clamped spline*. Only the direction of the tangent vector matters; the magnitude is not used.

COORDINATE SYSTEM

The coordinate system in which the curve coordinates above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the curve's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the interpolation curve consists of available as selections in all applicable selection lists (in physics and materials settings, for example),

choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection** (3D only), or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Interval

To create one or several intervals for a 1D geometry:

- Right-click the **Geometry** node and add an **Interval** node to the sequence then define it in the **Settings** window, or
- On the 1D **Geometry** toolbar **Primitives** group, click **Interval** (—). Or from the **Draw** group, click **Interval** and create an interval by clicking in the **Graphics** window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

When you have added a node or finished drawing intervals in the **Graphics** window, use the following section to define or fine tune them.

INTERVAL

From the **Specify** list, choose **Coordinates** (the default) to specify intervals using coordinates for the points that define the beginning and end of each interval, or choose **Interval lengths** to specify a left endpoint (staring point) and one or more interval lengths.

For **Coordinates**, choose a source from the **Coordinate source** list: The default is **Table**, for adding coordinates in a table of values below (the default is a single interval from 0 to 1). Alternatively, choose **Vector** to enter a vector of comma-separated or space-separated coordinates for the intervals' starting points and endpoints. Click the **Range** button (Range) to use the **Range** dialog box for specifying the vector of values for each coordinate.

For **Interval lengths**, first enter the coordinate of the starting point for the intervals in the **Left endpoint** field. Then choose a source from the **Length source** list: The default is **Table**, for adding interval lengths in a table of values below (the default is a single interval of length 1). Alternatively, choose **Vector** to enter a vector of comma-separated or space-separated lengths of the intervals. Click the **Range** button (Range) to use the **Range** dialog box for specifying the vector of values for each length.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, and boundaries — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains and boundaries) that the interval consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, or **Boundary selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Line Segment

A line segment is a line between a starting point or vertex and endpoint or vertex in 2D and 3D. In 2D, add a **Line Segment** node () by right-clicking the **Geometry** node and select it from the context menu in 2D or from the **More Primitives** submenu in 3D. In the **Geometry** ribbon, you can choose **Line Segment** from the **Primitives** menu in 2D and the **More Primitives** menu in 3D.

STARTING POINT

Define the starting point for the line segment. From the **Specify** list, choose **Vertex** (the default) to specify a start vertex by selecting a vertex from the geometry or using an applicable selection in the **Start vertex** list. Click the **Active** button to toggle between turning ON and OFF the start vertex selection. Alternatively, select **Coordinates** to specify the **x**, **y**, and (3D only) **z** coordinates for the starting point.

ENDPOINT

Define the endpoint for the line segment. From the **Specify** list, choose **Vertex** (the default) to specify an end vertex by selecting a vertex from the geometry or using an applicable selection in the **End vertex** list. Click the **Active** button to toggle between turning ON and OFF the end vertex selection. Alternatively, select **Coordinates** to specify the **x**, **y**, and (3D only) **z** coordinates for the endpoint.

COORDINATE SYSTEM

The coordinate system in which the coordinates above are interpreted (in 3D only, and if at least one of the **Specify** lists is set to **Coordinates**). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the line's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, and boundaries — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains and boundaries) that the interval consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Boundary selection** (2D or **Edge selection** (3D), or **Point selection**. The default is **Boundary selection** (2D) or **Edge selection** (3D). These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Parametric Curve

A parametric curve is a curve in 2D and 3D where you use a parameter to define the coordinates of the curve. For example, the coordinates $(s \cdot \cos(s), s \cdot \sin(s))$ for a parameter s that runs from 0 to 10π defines a spiral in 2D. To create a parametric curve, in the **Geometry** toolbar, from the **More Primitives** (3D  or 2D ) menu, select

Parametric Curve (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the parametric curve using the following sections:

PARAMETER

Define the parameter name in the **Name** field (default name: **s**). Also define the interval for the parameter values in the **Minimum** (default: 0) and **Maximum** (default: 1) fields.

EXPRESSIONS

Enter the expressions that define the functions of the parameter for each spatial coordinate in the **x**, **y** (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes), and (3D only) **z** fields. To create the spiral described earlier with the parameter s , type **s*cos(s)** in the **x** field and **s*sin(s)** in the **y** field.

Self-intersecting curves are not supported, except for closed curves (that is, when the starting point and endpoint coincide).

By default, the **x**, **y** (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes), and (in 3D) **z** expressions define the coordinates of points on the curve in the standard coordinate system. It is, however, possible to change this using the settings in the **Position**, **Axis** (3D only), and **Rotation Angle** sections. This is useful if you have created a parametric curve with the right shape but want to move it to another position or orientation. These settings can be thought of as defining a local coordinate system in which the parametric curve is defined.

Curves with self intersections might look correct when displayed but are not handled correctly by other geometry and meshing operations. This also applies if two different parts of the curve touch, even if they do not intersect. Simple closed curves are allowed, though.

POSITION

Enter the position of the local coordinate system origin using the **x**, **y** (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes), and (3D only) **z** fields.

AXIS

In 3D, enter the axis that you want to rotate the local coordinate system about. The axis can be chosen parallel to one of the coordinate axes or entered in Cartesian or spherical coordinates. The **z**-axis of the local coordinate system is parallel to this axis.

ROTATION ANGLE

Enter the angle you want the local coordinate system to be rotated (default: 0 degrees). In 2D the local coordinate system is rotated about its origin. In 3D, the local coordinate system is rotated about its **z**-axis, which is parallel to the axis defined in the previous section.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the curve's position).

ADVANCED SETTINGS

Internally, the software represents the parametric curve by a B-spline, which is computed to approximate the mathematical curve defined by the **x**, **y** in 2D, **r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes, and **x**, **y**, and **z** in 3D expressions. The number of knot points in the spline increases automatically until the curve approximation

satisfies the tolerance specified in the **Relative tolerance** field or until it reaches the number of knots specified in the **Maximum number of knots** field. The tolerance is measured relative to the space diagonal of the bounding box of the parametric curve.

If the parameterization of the curve is uneven or includes singularities, select the **Reparameterize using arc length** check box to reparameterize the curve, possibly providing a better parameterization without singularities.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the parametric curve consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Boundary selection** (2D only), **Edge selection** (3D only), or **Point selection**. The default is **Edge selection** in 3D and **Boundary selection** in 2D. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Parametric Surface

A parametric surface is a surface in 3D where you use two parameters to define the coordinates of the surface. For example, the coordinates $(s_1 \cdot \cos(s_2), s_1 \cdot \sin(s_2), s_2)$ for a parameter s_1 that runs from 0 to π , and a parameter s_2 that runs from -1 to 1 define a “twisted rectangle”. To create a parametric surface, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Parametric Surface** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the parametric surface using the following sections:

PARAMETERS

Define the parameter names in the **Name** fields (default names: **s1** and **s2**). Also define the intervals for the parameter values in the **Minimum** (default: 0) and **Maximum** (default: 1) fields.

EXPRESSIONS

Enter the expressions that define the functions of the parameter for each spatial coordinate in the **x**, **y**, and **z** fields. To create the twisted rectangle described earlier with the parameters s_1 and s_2 , type **s1*cos(s2)** in the **x** field, **s1*sin(s2)** in the **y** field, and **s2** in the **z** field.

By default, the **x**, **y**, and **z** expressions define the coordinates of points on the surface in the standard coordinate system. It is, however, possible to change this using the settings in the **Position**, **Axis**, and **Rotation Angle** sections. This is useful if you have created a parametric surface with the right shape but want to move it to another position or orientation. These settings can be thought of as defining a local coordinate system in which the parametric surface is defined.

Surfaces with self intersections might look correct when displayed but are not handled correctly by other geometry and meshing operations. This also applies to surfaces where one edge touches the surface of another edge, and to surfaces with singular points. If necessary, several parametric surfaces can be combined to overcome this limitation. For example, constructing a cylindrical shell by typing **cos(s1)** in the **x** field, **sin(s1)** in the **y** field, and **s2** in the **z** field, where **s1** runs from 0 to 2π , and **s2** runs from 0 to 1, is incorrect because two edges of the parametric

surface touch each other. Instead, use two parametric surfaces, with the same coordinate expressions, and where s_1 runs from 0 to π in the first surface and from π to 2π in the second one.

POSITION

Enter the position of the local coordinate system origin using the **x**, **y**, and **z** fields.

AXIS

Enter the axis that you want to rotate the local coordinate system about. The axis can be chosen parallel to one of the coordinate axes or entered in Cartesian or spherical coordinates. The **z**-axis of the local coordinate system is parallel to this axis.

ROTATION ANGLE

Enter the angle you want the local coordinate system to be rotated. The local coordinate system is rotated about its **z**-axis, which is parallel to the axis defined in the previous section.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the position).

ADVANCED SETTINGS

Internally, the software represents the parametric surface by a B-spline, which is computed to approximate the mathematical surface defined by the **x**, **y**, and **z** expressions. The number of knot points in the spline increases automatically until the surface approximation satisfies the tolerance specified in the **Relative tolerance** field or until it reaches the number of knots specified in the **Maximum number of knots** field. The tolerance is measured relative to the space diagonal of the bounding box of the parametric surface.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the parametric surface consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances if in a geometry part)** list: **All levels**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Point

To create points, you can:

- For all space dimensions, right-click the **Geometry** node and add a **Point** node to the sequence and then define it in the **Settings** window, or

- On the 1D **Geometry** toolbar **Primitives** group, click **Point** (). Or from the **Draw** group, click **Point** and create a point by clicking in the **Graphics** window. Also see [Drawing Geometric Primitives in the Graphics Window](#).
- On the 2D **Geometry** toolbar, from the **Primitives** () menu, select **Point**. Or from the **Draw** group, click **Point** and create a point by clicking in the **Graphics** window. Also see [Drawing Geometric Primitives in the Graphics Window](#).
- On the 3D **Geometry** toolbar, from the **More Primitives** () menu, you can also select **Point** (), which then adds a **Point** node to the sequence. You can then define the point's location in the **Settings** window for **Point**.

When you have added a node or finished drawing the point in the Graphics window, you can use the following section to define it or fine tune it.

POINT

Define the position of the point by entering its coordinates in fields labeled **x**, **y** (2D and 3D), and **z** (3D); **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. To get several points, enter a list of coordinates in each of these fields. Separate the coordinates with commas or blanks.

COORDINATE SYSTEM

The coordinate system in which the point coordinates above are interpreted (for points in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the point's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (points) that the point consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, or **Point selection**. The default is **Point selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Polygon

A polygon consists of a sequence of connected line segments. To create a polygon, right-click a 2D **Geometry** node and select **Polygon** (). For a 3D model, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Polygon**. You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the polygon using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid**, **Closed curve**, or **Open curve** to specify if the polygon is a solid object (only available in 2D) or a closed or open curve object. If you choose **Solid** or **Closed curve**, the program adds a line segment if needed to close the polygon.

When using [The Geometry Toolbar](#), the **Solid** button () is available to toggle between drawing a solid object or an outline (or curve) instead of selecting an **Object Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

COORDINATES

From the **Data source** list, you can choose from three different data sources for the coordinates:

- Select **Table** (the default) to specify the coordinates of the vertices in a table directly in the **Settings** window or load them from a file. Use the buttons underneath the table to move and remove rows, clear the table, and load and save table data.
- Select **File** to read vertex coordinate data from a text file where each row represents the x , y , and (in 3D) z coordinates for a vertex in the polygon. Specify the filename in the **Filename** field, or click the **Browse** button. The file must be a text file with the number of columns equal to the dimension of the geometry sequence and one row for each data point. The columns can be separated by space, tab, comma, or semicolon characters. The entries in the file should be numerical. In general, nonnumerical tokens and header lines are ignored. Click the **Import to Table** button to copy the file contents into the data point table and change the **Data source** to **Table**. Changes in the file do not automatically cause the polygon to be rebuilt. To rebuild the node after a change in the file, click the **Rebuild with Current File** button.
- Select **Vectors** to specify the coordinates of the vertices as vectors (lists) in the fields **x**, **y**, and **z** (3D only); **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. Each field can contain a list of numbers or expressions containing parameters, separated with commas or spaces. Click the **Range** button () to use the **Range** dialog box for specifying the vector of values for each coordinate.

COORDINATE SYSTEM

The coordinate system in which the polygon coordinates above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, and points) that the polygon consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection** (2D only), **Boundary selection** (2D only), **Edge selection** (3D only) or **Point selection**. The default is **Domain selection** in 2D and **Edge selection** in 3D. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Pyramid

To create a rectangular pyramid or pyramid frustum, in the **Geometry** toolbar, from the **More Primitives** () menu, select **Pyramid** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the pyramid using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the pyramid is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the size and shape of the pyramid in the **Base length 1**, **Base length 2**, **Height**, **Ratio**, **Top displacement 1**, and **Top displacement 2** fields. The **Base length** fields determine (default: 1) the side lengths of the bottom rectangle. The **Height** field (default: 1) determines the height of the pyramid frustum. The **Ratio** field (default: 0.5) controls the ratio of the perimeters of the top and bottom rectangles. To get an oblique pyramid, use the **Top displacement** fields (default: 0) to specify the displacement of the top rectangle's center relative to the bottom rectangle's center, in the pyramid's local coordinate system.

POSITION

Enter the position of the pyramid using the **x**, **y**, and **z** fields. This is the center of the bottom rectangle.

AXIS

Specify the direction of the third axis of the pyramid's local coordinate system — that is, the normal to the base rectangle. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero (the default), the second axis of the pyramid's local coordinate system (corresponding to **Base length 2**) is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the pyramid's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the pyramid consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Rectangle

To create a rectangle, you can:

- Right-click the **Geometry** node and add a **Rectangle** node to the sequence then define it in the **Settings** window, or
- In the **Geometry** toolbar **Draw** group, from the **Rectangle** () menu, select **Rectangle** () or **Rectangle (Center)** (). Then draw the rectangle in the **Graphics** window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

To draw a rectangle for a 2D model, click **Rectangle** or **Rectangle (Center)**. Then, click one corner (or the center) of the rectangle in the **Graphics** window. Drag the mouse to the desired position of a corner. When you release the mouse button, a solid rectangle appears, and a **Rectangle** node appears in the geometry sequence.

When you have added a node or finished drawing the rectangle in the **Graphics** window, you can use the following section to define it or fine tune it.

OBJECT TYPE

From the **Type** list, select **Solid** or **Curve** to specify if the rectangle is a solid object or a curve object.

When using the geometry toolbar, the **Solid** button () is available to toggle between drawing a solid object or an outline (or curve) instead of selecting an **Object Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

SIZE AND SHAPE

Define the size and shape of the rectangle in the **Width** and **Height** fields.

POSITION

Enter the position of the rectangle using the **x** and **y** fields (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes). From the **Base** list, choose **Center** if the rectangle is centered about the position, or choose **Corner** if the rectangle has a corner at the position.

ROTATION ANGLE

Specify the counterclockwise rotational angle (default: 0 degrees) about the position the **Rotation** field.

LAYERS

Layers can be used to create sandwich primitives by adding layers on one or more sides. You specify the thicknesses of layers in the **Layers** table, and optionally a name for each layer. The outermost layer comes first. Select the check boxes to specify where to apply the layers. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or

one of the types of resulting entities (domains, boundaries, edges, and points) that the rectangle consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Sphere

To create a sphere or ball, in the **Geometry** toolbar click **Sphere** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the sphere using the following sections:

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the sphere is a solid object or a (hollow) surface object.

SIZE

Define the radius of the sphere in the **Radius** field.

POSITION

Enter the position of the sphere's center using the **x**, **y**, and **z** fields.

AXIS

Specify the direction of the third axis of the sphere's local coordinate system. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero (the default), the second axis of the sphere's local coordinate system is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the sphere's position).

LAYERS

Layers can be used to create sandwich primitives by adding several concentric spheres. You specify the thicknesses and, optionally, names of each layer in the **Layers** table. The outermost layer comes first. The layers are positioned inside the sphere's radius. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the sphere consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Square

To create a square, you can:

- Right-click the **Geometry** node and add a **Square** node to the sequence, then define it in the **Settings** window, or
- In the **Geometry** toolbar **Draw** group, from the **Rectangle** () menu, select **Square** () or **Square (Center)** (). Then draw the square in the Graphics window. Also see [Drawing Geometric Primitives in the Graphics Window](#).

To draw a square, click **Square** or **Square (Center)**. Then, click one corner (or the center) of the square in the Graphics window. Drag the mouse to the desired position of a corner. When you release the mouse button, a solid square appears, and a **Square** node is added to the geometry sequence.

When you have added a node or finished drawing the square in the Graphics window, you can use the following section to define it or fine tune it.

OBJECT TYPE

From the **Type** list, select **Solid** or **Curve** to specify if the square is a solid object or a curve object.

When using the geometry toolbar, the **Solid** button () is available to toggle between drawing a solid object or an outline (or curve) instead of selecting an **Object Type**. See [Geometry Drawing Toolbar Buttons](#) for other drawing toolbar buttons.

SIZE

Define the size of the square in the **Side length** field.

POSITION

Enter the position of the square using the **x** and **y** fields (**r** and **z** in 2D axial symmetry, **xw** and **yw** in work planes). From the **Base** list, choose **Center** if the square is centered about the position, or choose **Corner** if the square has a corner at the position.

ROTATION ANGLE

Specify the counterclockwise rotational angle about the position the **Rotation** field.

LAYERS

Layers can be used to create sandwich primitives by adding layers on one or more sides. You specify the thicknesses of layers in the **Layers** table and optionally a name for each layer. The outermost layer comes first. Select the check boxes to specify where to apply the layers. Each layer must have a minimal thickness (depending on the size of the geometry).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the square consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Tetrahedron

To create a tetrahedron, in the **Geometry** toolbar, from the **More Primitives** (⊕) menu, select **Tetrahedron** (△). You can also right-click the **Geometry** node to add this node from the context menu.

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the tetrahedron is a solid object or a (hollow) surface object.

VERTICES

Define the position, size, and shape of the tetrahedron by specifying the coordinates of its vertices. Vertices 1–3 are the vertices of the bottom face in clockwise order. Vertex 4 is the top vertex.

COORDINATE SYSTEM

The coordinate system in which the coordinates of the vertices above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the **Graphics** window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the tetrahedron's position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the tetrahedron consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available

outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Torus

To create a torus, in the **Geometry** toolbar, from the **More Primitives** (⊕) menu, select **Torus** (⊗). You can also right-click the **Geometry** node to add a **Torus**.

OBJECT TYPE

From the **Type** list, select **Solid** or **Surface** to specify if the torus is a solid object or a (hollow) surface object.

SIZE AND SHAPE

Define the size and shape of the torus in the **Major radius**, **Minor radius**, **Revolution angle** and **Interior faces** fields. The **Major radius** (default: 1) field controls the distance from the center of the cross section to the center of the torus. The **Minor radius** (default: 0.5) field controls the radius of the cross section. To get less than a full revolution (360 degrees, the default), use the **Revolution angle** field. Select the **Interior faces** check box to create cross-sectional faces that partition the domain of a **Solid** torus.

POSITION

Enter the position of the torus' center using the **x**, **y**, and **z** fields.

AXIS

Specify the direction of the third axis of the torus' local coordinate system — that is, the normal to the plane of directrix circle. From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

ROTATION ANGLE

Specify the rotational angle about the axis in the **Rotation** field. When this angle is zero, the second axis of the torus' local coordinate system is parallel to the *xy*-plane.

COORDINATE SYSTEM

The coordinate system in which the position, axis, and rotation angles above are interpreted. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appear in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the position of the torus).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the torus consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These

selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Composite Object (Backward Compatibility)

If you open a model from an older version of COMSOL Multiphysics (versions 4.0–5.2a), and it was originally created in the 3.5a version of COMSOL Multiphysics, one **Composite Object** node () appears for each nonprimitive geometry object in the model. The **Composite Object** node contains the following sections.

COMPOSITE OBJECT

If you save the model as a `.java` file, COMSOL Multiphysics uses the filename specified in the **Filename** field to determine the path to a geometry file, containing the geometry object, that appears together with the `.java` file. The software uses this geometry file when you run the resulting `.java` file. By default, the filename has the prefix `$FILENAME$`. If the filename starts with this prefix, COMSOL Multiphysics stores the geometry file in the same directory as the `.java` file. It is also possible to remove this prefix and specify the full path to the geometry file.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the object consists of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Geometry Operations

This section describes the available geometry operations ([Work Plane Operations](#), [Boolean and Partition Operations](#), [Transform Operations](#), [Conversion Operations](#), [Other Geometry Operations](#), and [Programming](#)). The features in [Table 7-2](#), [Table 7-3](#), [Table 7-4](#), [Table 7-5](#), and [Table 7-6](#), are also available as buttons on [The Geometry Toolbar](#).

See [Virtual Geometry and Mesh Control Operations](#) for examples of how to use virtual geometry operations to remove a short edge and to ignore and collapse edges to prepare the geometry for efficient meshing. You can use several of these operations to also control the mesh.

WORK PLANE OPERATIONS

The following table lists operations available with work planes in 3D geometries:

TABLE 7-2: WORK PLANE RELATED OPERATIONS FOR 3D MODELS

ICON	NAME	DESCRIPTION
	Cross Section	Create a 2D cross section from an intersection between a 3D geometry and a work plane.
	Extrude	Extrude planar objects into 3D.
	Revolve	Revolve planar objects into 3D.
	Sweep	To sweep one or several faces along a spine curve.
	Work Plane	Create a work plane for drawing 2D objects that are embedded in 3D.

BOOLEAN AND PARTITION OPERATIONS

Use Boolean and Partition operations to create a *composite geometry object* by forming unions, set differences, and set intersections — and combinations of those operations — of existing geometry objects.

The following Boolean and Partitions operations are available in all space dimensions:

TABLE 7-3: BOOLEAN AND PARTITION OPERATIONS

ICON	NAME	SPACE DIMENSION	DESCRIPTION
	Compose	ID, 2D, 3D	Compose geometry objects by specifying Boolean operations using a set formula.
	Difference	ID, 2D, 3D	Select the objects to compose in the Graphics window and click the Difference button to take the selected object with the largest volume (area, length) and subtract the others.
	Intersection	ID, 2D, 3D	Select the objects to intersect in the Graphics window and click the Intersection button to create an intersection of the selected objects.
	Partition Objects	ID, 2D, 3D	Partition geometry objects using a work plane or other geometry objects (tool objects).
	Partition Domains	2D, 3D	Partition selected domains using lines or edges.
	Partition Edges	2D, 3D	Partition selected edges at specified locations.

TABLE 7-3: BOOLEAN AND PARTITION OPERATIONS

ICON	NAME	SPACE DIMENSION	DESCRIPTION
	Partition Faces	3D	Partition selected faces at specified locations.
	Union	ID, 2D, 3D	Select the objects to unite in the Graphics window and click the Union button to create a union of the selected objects.

TRANSFORM OPERATIONS

You can use the transforms to create rectangular and linear arrays of identical geometry objects and to move, rotate, mirror, and scale geometry objects. Mirroring, moving, rotating, and scaling are *affine transformations* applied to geometry objects. All transforms are available in all space dimensions, except Rotate, which is not applicable for 1D geometries.

TABLE 7-4: GEOMETRY TRANSFORM OPERATIONS

ICON	NAME	SPACE DIMENSION	DESCRIPTION
	Array	ID, 2D, 3D	Create an array of geometry objects.
	Copy	ID, 2D, 3D	Copy geometry objects.
	Mirror	ID, 2D, 3D	Mirror geometry objects in a plane (3D), a line (2D), or a point (1D).
	Move	ID, 2D, 3D	Move geometry objects.
	Rotate	2D, 3D	Rotate geometry objects about a centerpoint.
	Scale	ID, 2D, 3D	Scale geometry objects about a centerpoint.

CONVERSION OPERATIONS

The geometry conversion operations make it possible to, for example, convert a 3D solid to a surface (boundary) object for modeling a shell or other thin structure. You can perform the following geometry object conversions:

	For 2D models: <ul style="list-style-type: none"> Convert a solid object into a curve or point object. Convert a curve object defining at least one closed domain into a solid object. Convert a curve object into a point object.
	For 3D models: <ul style="list-style-type: none"> Convert a solid object into a surface, curve, or point object. Convert a surface object defining at least one closed domain into a solid object. Convert a surface object into a curve or point object. Convert a curve object into a point object.

TABLE 7-5: GEOMETRY CONVERSION OPERATIONS

ICON	NAME	SPACE DIMENSION	DESCRIPTION
	Convert to Curve	2D, 3D	Select the objects to convert in the Graphics window and click to unite them and convert them to a curve object.
	Convert to Point	ID, 2D, 3D	Select the objects to convert in the Graphics window and click to unite them and convert them to a point object.
	Convert to Solid	ID, 2D, 3D	Select the objects to convert in the Graphics window and click to unite them and convert them to a solid object.
	Convert to Surface	3D	Select the objects to convert in the Graphics window and click to unite them and convert them to a surface object.
	Convert to COMSOL	3D	Available with the CAD Import Module. Select the objects to convert in the Graphics window, and then click to convert them to a COMSOL kernel representation. See the <i>CAD Import Module User's Guide</i> .
	Split	ID, 2D, 3D	Split one or several objects into their entities.

OTHER GEOMETRY OPERATIONS

For 2D geometry objects, you can use geometry operations such as fillets and tangents to construct the geometry. In all space dimensions you can delete geometry objects or geometric entities (domains, boundaries, edges, and points).

The following table provides an overview of available general geometry operations:

TABLE 7-6: OTHER GEOMETRY OPERATIONS

ICON	NAME	SPACE DIMENSION	DESCRIPTION
	Chamfer	2D	Create chamfers at a set of corners of a 2D geometry object.
	Fillet	2D	Create fillets at a set of corners of a 2D geometry object.
	Tangent	2D	Create a tangent from an edge to another edge or point in a 2D geometry.
	Delete Entities	ID, 2D, 3D	To delete geometric entities (domains, boundaries, edges, or points) from the objects they belong to, or to delete entire geometry objects, select the entities or objects and click the Delete button. If you delete objects corresponding to primitive features, these nodes are removed from the sequence. If you delete other objects or geometric entities, a Delete Entities node is added to the sequence. If instead you use the Delete Entities context menu item, a Delete Entities always displays.
	Edit Object	2D	To edit a 2D object using the Settings window, in the Model Builder, right-click the Geometry node and select Edit Object from the context menu. To edit a 2D object using the Graphics window, select the object and click the Edit Object button. See Editing 2D Geometry Objects .
	Import	ID, 2D, 3D	Import geometry objects from a file or from another geometry.

PARTS

You can use parts to simplify the geometry modeling with custom parts that can be reused and created as part instances in a geometry sequence:

TABLE 7-7: PARTS

ICON	NAME	DESCRIPTION	SEE
	Part Libraries	Open the Part Libraries window.

PROGRAMMING

You can use If, Else If, Else, and End If nodes to create If statements that enable or disable other features depending on values of logical conditions in terms of parameters. The Parameter Check node makes it possible to check the value of parameters (for example, to limit the value of an input parameter).

TABLE 7-8: PROGRAMMING AND LOGICAL OPERATIONS

ICON	NAME	DESCRIPTION	SEE
	If	Begin an If statement.	If, Else If, Else, End If
	Else If	Continue an If statement.	
	Else	Last alternative in an If statement.	
	End If	End an If statement.	
	Parameter Check	Check the value of parameters.	

Array

To create a block-shaped (3D), rectangular (2D, 3D), or linear array of identical geometry objects, in the **Geometry** toolbar **Transforms** () menu, select **Array** (). You can also right-click the **Geometry** node to add this node from the **Transforms** submenu. Then enter the properties of the array operation using the following sections:

INPUT

Select the geometry objects that you want to duplicate in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Array** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

SIZE

In 2D and 3D, you get a rectangular (in 2D) or three-dimensional (in 3D) array by default. Enter the number of duplicates in each coordinate direction in the **x size**, **y size**, and **z size** fields; **r size** and **z size** in 2D axial symmetry; **xw size** and **yw size** in work planes.

To create a linear array of objects in 2D or 3D, change **Array type** to **Linear**. Enter the number of duplicates in the **Size** field.

In 1D, enter the number of duplicates in the **Size** field.

DISPLACEMENT

Set the displacement in each coordinate direction in the **x**, **y**, and **z** fields (not all fields are available in 1D and 2D).

COORDINATE SYSTEM

The coordinate system in which the displacement coordinates above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the array displacement).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Chamfer

Use a **Chamfer** (

POINTS

Select the points (vertices) that you want to chamfer in the Graphics window. They then appear in the **Vertices to chamfer** list. If the geometry sequence includes user-defined selections above the **Chamfer** node, choose **Manual** to select points, or choose one of the selection nodes from the list next to **Vertices to chamfer**.

Click the **Active** button to toggle between turning ON and OFF the **Vertices to chamfer** selections.

DISTANCE

In the **Distance from vertex** field, enter the distance from the vertex to the endpoints of the chamfer segment.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection

nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To chamfer corners in 2D geometry objects, in the **Geometry** toolbar click **Chamfer** (). You can also right-click the **Geometry** node to add this node from the context menu.

The Design Module supports chamfering of corners in 3D geometries.

Compose

To create a composite geometry object from other geometry objects using Boolean operations given in a set formula, use a **Compose** () node. Enter the properties of the compose operation as a set formula using the following sections:

COMPOSE

Select the geometry objects that you want to compose in the Graphics window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Compose** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected solid geometry objects for further geometry operations.

In the **Set formula** field, enter a set formula involving the names of the selected geometry objects — for example, $r1+c1*(c2-r2)$ — to take the union of $r1$ and the object that is the result of the intersection between $c1$ and the set difference where $r2$ is subtracted from $c2$. Use the binary operations +, *, and - for set union, set intersection, and set difference, respectively. The precedence of the operators + and - are the same. The operator * has higher precedence. You can override the precedence rules using parentheses. When you change the set formula, the **Input objects** selection is automatically updated.

To create a geometry object without interior boundaries, clear the **Keep interior boundaries** check box. This can be useful to simplify a geometry where the interior boundaries do not separate domains with different physics nodes or materials, for example.

You can change the settings for the **Repair tolerance** list if you experience problems with the compose operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

In the **Geometry** toolbar, from the **Boolean and Partitions** (□) menu, select **Compose** (⊕). You can also right-click the **Geometry** node to add this node from the **Boolean and Partitions** submenu.

Convert to Curve

Use the **Convert to Curve** (▣) node to unite and convert geometry objects to a single curve object. Enter the properties of the convert operation using the following section:

INPUT

Select the geometry objects that you want to convert in the Graphics window. The objects appear in the **Input objects** list.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

You can change the settings for the **Repair tolerance** list if you experience problems with the convert operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Boundary selection** (2D), **Edge selection** (3D), or **Point selection**. The default is **Boundary selection** in 2D and **Edge selection** in 3D. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To unite and convert geometry objects to a single curve object, in the **Geometry** toolbar, **Conversions** menu, click **Convert to Curve** (✉). You can also right-click the **Geometry** node to add this node from the **Conversions** submenu.

Convert to Point

Use the **Convert to Point** (✉) node to unite and convert geometry objects to a single point object. Enter the properties of the convert operation using the following sections:

INPUT

Select the geometry objects that you want to convert in the Graphics window. The objects appear in the **Input objects** list.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

You can change the settings for the **Repair tolerance** list if you experience problems with the convert operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a

work plane in a 3D component) list: **All levels** or **Point selection**. The default is **Point selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To unite and convert geometry objects to single a point object, in the **Geometry** toolbar, **Conversions** menu, click **Convert to Point** (). You can also right-click the **Geometry** node to add this node from the context menu.

Convert to Solid

Use the **Convert to Solid** () node to unite and convert geometry objects to a single solid object. Enter the properties of the convert operation using the following sections:

INPUT

Select the geometry objects that you want to convert in the Graphics window. The objects appear in the **Input objects** list.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

You can change the settings for the **Repair tolerance** list if you experience problems with the convert operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To unite and convert geometry objects to single a solid object, in the **Geometry** toolbar, **Conversions** menu, click **Convert to Solid** (). You can also right-click the **Geometry** node to add this node from the context menu.

Convert to Surface

Use the **Convert to Surface** () node to unite and convert geometry objects to a single surface object in a 3D geometry. You can, for example, convert a solid geometry to a surface object for modeling some type of shell. If the input objects include edges or curves, then any parts of those edges or curves that are outside of the resulting surfaces are removed. If the conversion to a surface results in an empty surface, a **Warning** subnode appears.

It is not possible to create a 3D surface from a set of connected curves or edges, even if they all lie in a plane and could form a planar surface. In such cases, you can instead create a work plane where you add the connected curves and then create a surface from those curves. If your license includes the CAD Import Module, you can also use a Cap Faces feature to create a surface from a set of connected curves.

Enter the properties of the convert operation using the following sections:

INPUT

Select the geometry objects that you want to convert in the Graphics window. The objects appear in the **Input objects** list.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

You can change the settings for the **Repair tolerance** list if you experience problems with the convert operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Boundary selection**, **Edge**

selection, or **Point selection**. The default is **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To unite and convert geometry objects to a single surface object, in the **Geometry** toolbar, **Conversions** menu, click **Convert to Surface** (). You can also right-click the **Geometry** node to add this node from the context menu.

Copy

Use the **Copy** () node to make a displaced copy of one or several geometry objects. This method creates a node in the model tree that contains a reference to other objects in the geometry sequence that are copied and keeps the objects linked (unlike a simple copy and paste function). Enter the properties of the copy operation using the following sections:

INPUT

Select the geometry objects that you want to copy in the Graphics window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Copy** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Clear the **Keep input objects** check box to remove the input objects.

DISPLACEMENT

Set the displacement in each direction by entering **x**, **y**, and **z** (not all fields are available in 1D and 2D); **r** and **z** in 2D axial symmetry; or **xw** and **yw** in work planes. To create several copies, enter a comma-separated or space-separated list of displacements in these fields or click the **Range** button () to use the **Range** dialog box for specifying a range of displacements for multiple copies.

COORDINATE SYSTEM

The coordinate system in which the displacement coordinates above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the copy operation's displacement).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection

nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

LOCATION IN USER INTERFACE

To create copies of geometry objects, in the **Geometry** toolbar **Transforms** () menu, select **Copy** (). You can also right-click the **Geometry** node to add this node from the **Transforms** submenu.

	To copy geometry features, you can also right-click the geometry feature in the model tree (for example, Rectangle or Sphere) and select Copy (). Then right-click the Geometry node and select Paste (for example, Paste Rectangle or Paste Sphere) (). It is also possible to copy and duplicate nodes corresponding to operation features such as the Union node.
	<ul style="list-style-type: none">• Copying, Pasting, and Duplicating Nodes• Copying and Pasting Geometry Objects

Cross Section

In a **Work Plane** node's **Plane Geometry** sequence you can add a **Cross Section** node (). By default, this computes the cross section of all 3D objects generated by preceding nodes in the geometry sequence. You can also select specific 3D objects to intersect with the work plane. You can also add a new 2D or 2D axisymmetric **Component** and add the **Cross Section** node there. In that case, you can select which **Work Plane** to use. For example, if you have a 3D geometry that is symmetric about an axis, you can add a work plane that contains the axis. In the axisymmetric 2D Component, you then get the cross section and can use a 2D axisymmetric component, which is computationally efficient compared to a full 3D component. A **Cross Section** node can also be useful to extract a planar surface for modeling a thin flat 3D structure using shell elements, for example. Another use for a cross section is to form a surface that you can extrude into a 3D solid from a closed curve that lie in a plane. Then also add a **Convert to Solid** node below the **Cross Section** node to make the closed curve into a 2D surface.

To add a cross section, right-click a **Plane Geometry** node under a **Work Plane** node or a 2D **Geometry** node and select **Cross Section** (). Then enter the properties of the cross section using the following sections:

CROSS SECTION

If you add the **Cross Section** node to a 2D or 2D axisymmetric geometry, first select the work plane to use for the cross section from the **Work plane** list.

From the **Intersect** list, choose **All objects** (the default) to intersect all 3D geometry objects with the work plane, or choose **Selected objects** to intersect only the geometry objects that you add to the **Objects to intersect** list that appears. Click the **Active** button to toggle between turning ON and OFF the **Objects to intersect** selections.

You can change the settings for the **Repair tolerance** list if you experience problems with the cross section operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .

- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. Use the **Show in 3D** list (for **Cross Section** nodes in a **Work Plane** node's **Plane Geometry**) or the **Show in physics** list (or **Cross Section** nodes in 2D or 2D axisymmetric geometries) to choose for which geometric entity level the selection should be created. All applicable levels, as well as **All levels** and **Off**, are available. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Select the **Selections from 3D** check box to create selections in 2D based on the selections from the 3D geometry. Each selection that is produced by a 3D geometry feature preceding the work plane in the 3D geometry sequence and each 3D cumulative selection are intersected with the work plane to give a selection in 2D. These selections are available if the **Cross Section** node under a **Plane Geometry** node in a work plane or under a 2D component's **Geometry** node. In the latter case, you can also select the **Show in physics** check box to make the selections from 3D available in physics and materials settings, for example.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Deformed Configuration

To create a geometry from a (deformed) mesh:

- In the **Results** toolbar, select **Attributes>Remesh Deformed Configuration** (- Under **Results>Data Sets**, right-click a **Solution** data set and select **Remesh Deformed Configuration** (

The new geometry is added under **Meshes** as a **Deformed Configuration** node (Settings window of this node, the **Time** or **Parameter value** list controls which solution is used to generate the deformed configuration. If you change the time or parameter value, or if the solution itself has changed, update the deformed configuration by clicking the **Update** button. The meshes that belong to the deformed configuration appear as child nodes under the deformed configuration node. Thus, to remesh the deformed configuration, right-click such a mesh node and select **Build All**.

- [Remeshing a Deformed Mesh](#)
 - [Solution \(data set\)](#)
-

Delete Entities

To delete geometry objects or geometric entities from objects, right-click a geometry and select **Delete Entities** (Input section. If you delete objects

corresponding to primitive features these nodes disappear from the sequence. If you delete other objects or if you delete geometric entities a Delete Entities node appears in the sequence.

If you want to delete all objects created by a feature, it is better to right-click the feature, and select **Delete** () or **Disable** ().

ENTITIES OR OBJECTS TO DELETE

From the **Geometric entity** level list, choose the level of the entities to delete: **Object**, **Domain**, **Boundary** (that is, faces in 3D and edges in 2D), **Edge** (3D only), or **Point**. Then select the objects or entities that you want to delete in the **Graphics** window or use the **Selection List** window. The objects appear in the **Selection** list when you have confirmed (locked) the selection in the **Graphics** window. If the geometry sequence includes user-defined selections above the **Delete Entities** node, choose **Manual** to select objects or entities, or choose one of the selection nodes from the list next to **Selection**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Difference

To subtract geometry objects from other geometry objects to make a set difference, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Difference** (). You can also right-click the **Geometry** node to add this node from the **Boolean and Partitions** submenu. Then enter the properties of the difference operation using the following section:

DIFFERENCE

Activate the **Objects to add** list by clicking the **Active** button to toggle between turning ON and OFF selections. When set to ON, select the objects that you want to add in the **Graphics** window. If the geometry sequence includes user-defined selections above the **Difference** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Objects to add**.

Activate the **Objects to subtract** list by clicking the **Active** button to toggle ON and OFF. When set to ON, select the objects that you want to subtract in the **Graphics** window. If the geometry sequence includes user-defined selections above the **Difference** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Objects to subtract**.

Click the **Swap Objects to Add and Objects to Subtract** button () to swap the objects in the two lists.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

Create a geometry object without interior boundaries by clearing the **Keep interior boundaries** check box. This can be useful to simplify a geometry where the interior boundaries do not separate domains with different physics nodes or materials, for example.

You can change the settings for the **Repair tolerance** list if you experience problems with the difference operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Edit Object

Use the **Edit Object** () feature to adjust the edges and vertices for a 2D geometry object or to add or delete edges and vertices in the object. To edit a 2D object using the **Settings** window, in the Model Builder, right-click the Geometry node and select **Edit Object** from the context menu. To edit a 2D object using the Graphics window, select the object and click the **Edit Object** button. See [Editing 2D Geometry Objects](#).

SELECT OBJECT

Select the **Input object** to edit in the **Graphics** window (any applicable geometry object or selection). When selected, a copy is made of the input object, and changes then operate on this copy. Changes made in the **Input object** after the copy has been made has no effect on the **Edit Object** feature. For this reason, it is not possible to change the **Input object** after it has been selected.

Click the **Active** button to toggle between turning ON and OFF the **Input object** selections.

EDIT EDGES

Click the **Active** button to toggle between turning ON and OFF the **Edge** selections.

In the **Graphics** window, select and add the **Edge** to edit (or use [The Selection List Window](#)). The parameters for the current edge are displayed in the table for **x (m)**, **y (m)**, **(xw (m))**, **yw (m)** in work planes — where the **m** in parentheses indicates the current geometry length unit; in this case the default unit: meter — and **Weights**, and under the table for the **Degree** list and the **Start vertex** and **End vertex** fields.

If required, click **New** to create a new edge. The new edge is linear, not connected to any other edges or vertices, and has both the start and the end coordinates set to 0. Click **Delete** to delete the current edge. Deleting an edge also deletes its adjacent vertices, if these vertices are not connected to other edges.

Click in the table cells to edit the **x (m)**, **y (m)**, **(xw (m))**, **yw (m)** in work planes) and **Weights** and modify the control points of the edge. If the **x** or **y** value for the first or last control point is modified, any adjacent edges and vertices are automatically updated with the same value.

Select the **Degree** — **Linear**, **Quadratic**, or **Cubic** — to change the degree of the edge. When decreasing the degree, the control points are recalculated so as to approximate the old shape of the edge.

Under **Start vertex**, click the **Active** button to move the starting point of the edge to a different vertex. In the **Graphics** window, select and add the **Edge**. Under **End vertex**, click the **Active** button to move the endpoint of the edge to a different vertex. In the **Graphics** window, select and add the **Edge**. If required, click **Disconnect** to disconnect the start or end vertex of an edge from the rest of the object. A new vertex is created with coordinates matching the start or endpoint of the edge. This vertex can be moved without affecting the other edges that were previously connected to this edge.

When the **Edit Object** node is the current node, you can visualize the edited object by observing the edge or vertex numbers displayed in the **Graphics** window next to the edges or vertices.

EDIT VERTICES

Click the **Active** button to toggle between turning ON and OFF the **Vertex** selections.

In the **Graphics** window, select and add the **Vertex** (node) to edit (or use [The Selection List Window](#)). The parameters for the current vertex are displayed in the **x** and **y** fields under **Coordinates**, and the vertex is highlighted in the **Graphics** window.

- Click **New** to create a new vertex; the coordinates for the new vertex are set to 0.
- Click **Delete** to delete the current vertex. Only isolated vertices can be deleted. For other vertices, the **Delete** button is disabled.
- Click **Snap to Closest** to delete the current vertex. Any edges connected to the deleted vertex are modified so that the start or endpoint is moved to the closest remaining vertex.

Under **Coordinates** edit the **x** and **y** fields as needed.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the

model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Editing 2D Geometry Objects

Extrude

To extrude planar objects into 3D objects, in the **Geometry** toolbar, click **Extrude** (). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the context menu. Then enter the properties of the extrude operation.

GENERAL

From the **Extrude from** list, select **Faces** to extrude planar faces from the 3D geometry. Select the faces that you want to extrude in the Graphics window. They appear in the **Input faces** list. All selected faces must lie in the same plane. Alternatively, from the **Extrude from** list, select **Work plane** to extrude objects from a work plane. In the **Work plane** list, select the work plane to extrude from. Select the objects that you want to extrude in the Graphics window. They appear in the **Input objects** list.

From the **Input object handling** list, select one of the following options:

- **Unite with** (the default), to unite the input objects with the extruded objects.
- **Keep**, to keep the extruded objects separate from the input objects.
- **Remove**, to avoid that the input faces appear in the **Form Union** operation. This option is useful if you extrude in both directions and have cleared the **Include input faces** check box in the **DISTANCES** section below.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

DISTANCES

From the **Specify** list, choose **Distances from plane** (the default) or **Vertices to extrude to**.

For **Distances from plane**, specify one or several distances (positive or negative) in the table. These determine the height above or below the work plane or planar faces for the top of each layer. The **Reverse direction** check box reverses the direction of the extrusion. To achieve a symmetric extrusion for a total thickness th , enter two distances: $th/2$ and $-th/2$.

For **Vertices to extrude to**, select vertices to extrude the planar objects to from the list or by selecting them in the Graphics window.

Select the **Include input faces** check box (selected by default) to also include a face of the extruded objects at their input location (the work plane). If you clear this check box, you do not get a face at the work plane, so the number of distances from the plane must be at least 2. Likewise, if you extrude to a single vertex, you need to include the input faces as a second end face for the extruded objects.

If you extrude several layers, remove the interior boundaries by clearing the **Keep cross-sectional faces** check box.

The direction arrow that appears in the Graphics window indicates the length of each extrusion distance.

SCALES

For each layer, specify a length scaling factor for the top of the layer relative to the work plane object or planar faces.

DISPLACEMENTS

For each layer, specify a displacement vector for the top of the layer in the work plane's coordinate system, or the local coordinate system defined by the first face to extrude. The first face is the face with smallest face number in the geometry object that comes first in the geometry sequence.

TWIST ANGLES

For each layer, specify a rotation angle for the top of the layer around the work plane's normal vector or the normal vector of the first face to extrude. The first face is the face with smallest face number in the geometry object that comes first in the geometry sequence.

POLYGON RESOLUTION OF EDGES

This setting determines how accurately the edges in the extrusion direction are represented.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Fillet

To fillet (round) corners in 2D geometry objects, in the **Geometry** toolbar, click **Fillet** (). You can also right-click the **Geometry** node and add this node from the context menu. Then enter the properties of the fillet operation using the following sections:

POINTS

Select the points (vertices) that you want to fillet in the **Graphics** window. They then appear in the **Vertices to fillet** list. If the geometry sequence includes user-defined selections above the **Fillet** node, choose **Manual** to select points, or choose one of the selection nodes from the list next to **Vertices to fillet**.

Click the **Active** button to toggle between turning ON and OFF the **Vertices to fillet** selections.

RADIUS

Enter the **Radius** of the circular fillet arc.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

The Design Module supports fillets in 3D geometries.

If, Else If, Else, End If

To construct an If statement, in the **Geometry** toolbar, from the **Programming** menu, select **If + End If** (you can also do this by right-clicking the **Geometry** node in the model tree and opening the **Programming** submenu). This adds an **If** node (?) and an **End If** node (?) after the current node. You can optionally add **Else If** (?) nodes and an **Else** node (?) in a similar way. To add these nodes at an arbitrary position in a geometry sequence, you can right-click a geometry feature node and select **If**, **Else If**, **Else**, or **End If** on the **Add Before** or **Add After** submenu. This adds the selected type of programming feature before or after the selected node, without building the preceding feature node.

An If statement has the following structure:

```
If
  <branch1>
Else If
  <branch2>
Else If
  <branch3>
...
Else
  <last branch>
End If
```

where the **Else If** and **Else** nodes are optional. There can be an arbitrary number of geometry features in each branch, and there can be an arbitrary number of **Else If** nodes. The **Else** node must appear after all **Else If** nodes and before the **End If** node.

The *Thermal Microactuator Simplified* model in the Multiphysics section of the COMSOL Multiphysics Application Library uses If and End If nodes in its geometry sequence to consider different geometry cases.

If you have the CFD Module, the *Mixer* application's geometry sequence shows the use of If, Else If, and End If.

IF AND ELSE IF

The **Settings** windows for **If** and **Else If** have a **Condition** field, which contains a logical condition in terms of parameters (for example, $a+b>0$, where a and b are defined as parameters for the geometry sequence). In general, the condition is true if it evaluates to a nonzero value. When building the geometry sequence, the program builds the features in the first branch that has a true condition and treats the other branches as disabled. If none of the conditions are true, the program builds the **Else** branch.

If you select a feature in a branch and click **Build Selected**, the software pretends that the chosen branch has a true condition and that all other branches have false conditions. You can use this behavior to try out the different branches without having to change the parameters. If statements can be nested.

To define selections that have different definitions in different branches of an If statement, you can use cumulative selections (see [Cumulative Selections](#)).

Import

To import geometry objects from a file or from another geometry, in the **Geometry** toolbar, click **Import** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the import feature in the **Import** section of the **Settings** window for the **Import** node.

IMPORT

In the **Source** list choose the type of data to import: **Any importable file** and **COMSOL Multiphysics file** are always available. If there is another geometry sequence of the same dimension in the model, the type **Geometry sequence** is available. In addition, you can choose **Mesh** in 1D, **DXF file** or **Mesh** in 2D, and **Mesh or STL file** in 3D. When choosing **Mesh** or **Mesh or STL file**, you can import the geometry defined by a mesh of any meshing sequence, of the same space dimension, or a mesh file in the COMSOL Multiphysics format. In 3D, it is also possible to import a mesh defined by an STL, VRML, or NASTRAN file as a geometry. STL and VRML files, which represent 3D surface meshes, can be used as a basis for creating a volumetric mesh for a single geometry domain.

Importing a COMSOL Multiphysics geometry file that contains a geometry created using the CAD kernel requires the CAD Import Module,

In 2D and 3D (but not in work planes, where virtual operations are always excluded), when **COMSOL Multiphysics file** is selected from the **Source** list, the **Include result from virtual operations** check box is selected by default. Clear that check box if you want to exclude the virtual operations in the file when importing it into another geometry.

If you have license for the CAD Import Module, you also have **3D CAD file** in 3D (see the *CAD Import Module User's Guide* for more information about supported CAD file formats). You need to use the CAD kernel for the geometry representation, which you can specify in the **Preferences** dialog box and in the **Settings** window for **Geometry**.

The alternative import formats — **ECAD file (GDS)**, **ECAD file (NETEX-G)**, and **ECAD file (ODB++)** — are available in 2D and 3D with a license for the ECAD Import Module. See the *ECAD Import Module User's Guide* or go to <http://www.comsol.com/ecad-import-module/> for more information.

In all cases, you need to specify the geometry sequence, mesh, or file to import. Then click **Import** to bring in the geometry or mesh to use as a part of the geometry in the geometry sequence.

For the **Any importable file** and **COMSOL Multiphysics file** source types (and the 3D CAD and ECAD file source types), specify the filename in the **Filename** field or click the **Browse** button.

For import from another geometry sequence, select the geometry sequence or meshing sequence from the **Geometry** list below.

For import of a mesh, choose one of the available meshing sequences (from other model components of the same dimension) or mesh parts from the **Mesh** list. Use the **Go to Source** button () to move focus to the meshing sequence or mesh part that you selected. If you choose **None**, you can click **Browse** to locate a mesh or STL file or specify it in the **Filename** field. If you import an STL or NASTRAN file, for example, clicking **Import** also creates a **Mesh Part** node of the same dimension as the geometry component with an **Import** subnode under **Global Definitions** to make it easy to reuse the imported mesh as a geometry part. See [Import](#) for additional settings that you can make for the import in the mesh part and [Using Mesh Parts](#) for more information about mesh parts.

For DXF, mesh and STL, and 3D CAD import, you can change a number of properties when you have selected the file type. To import the file, click the **Import** button (). If you have changed some property, the software automatically re-imports the file when you click a build button. If you have changed the source file, you need to explicitly click the **Import** button to read the modified file.

Properties for Mesh or STL File Import

When you have selected a mesh or STL file, you can optionally simplify the mesh before creating the geometry. The simplification can remove small defects typically present in mesh data from measurements, such as tomography, and it can speed up geometry processing by removing unnecessary elements from all kind of meshes. Select the **Simplify mesh** check box to enable simplification.

The **Relative simplification tolerance** is relative to the dimensions of the entire geometry and specifies a global limit for how much the mesh can be modified. The **Defect removal factor** is relative to the local feature size, as estimated by the algorithm, and is combined with the global limit to produce a limit for how much the mesh can be modified at a certain location. If the mesh contains many defects that you want to remove, you could try to increase the value of the **Defect removal factor**. If the mesh describes the desired geometry with high accuracy, you may want to decrease this factor instead.

The **Form solids from surface objects** check box is selected by default to create solid geometry objects from surface mesh objects from, for example, an STL file. If you do not want or need solid geometry objects, clear this check box.

Properties for DXF Import

The repair tolerance specifies the largest distance between the endpoints of curves allowed in the imported geometry. You can specify this tolerance as an import option.

In the **Layer selection** list, select the layers to import.

Under **Import options**, select **Form solids** to unite and convert all objects in each layer to a solid object, select **Knit curves** to unite and convert all objects in each layer to a curve object, or select **Do not knit** to do nothing.

If the **Repair imported objects** check box is selected, enter a **Relative repair tolerance**. To create a geometry for mesh generation and finite element analysis, COMSOL Multiphysics requires a high degree of accuracy within the CAD drawing. Sometimes DXF geometries contain small gaps and exceedingly short edges that make it impossible to create a valid 2D solid or a valid mesh. COMSOL Multiphysics provides repair tolerance settings to remove short edges and close small gaps during DXF file import. The absolute repair tolerance is the relative repair tolerance times the maximum coordinate of the imported objects (the default value is 10^{-5}). Geometric entities that have a distance less than the absolute repair tolerance are merged.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Select the **Individual objects selections** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence for each individual object in the geometry file and for each relevant entity level. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, if available, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

	See the <i>ECAD Import Module User's Guide</i> or go to http://www.comsol.com/ecad-import-module/ for more information about selection settings for import of ECAD files.
	<i>Eigenmodes of a Room</i> : model library path COMSOL_Multiphysics/Acoustics/eigenmodes_of_room

Intersection

To create the intersection of geometry objects, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Intersection** (). You can also right-click the **Geometry** node to add this node from the **Boolean and Partitions** submenu. Then enter the properties of the intersection operation using the following section:

INTERSECTION

Select the geometry objects that you want to intersect in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Intersection** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

To create a geometry object without interior boundaries, clear the **Keep interior boundaries** check box. This can be useful to simplify a geometry where the interior boundaries do not separate domains with different physics nodes or materials, for example.

You can change the settings for the **Repair tolerance** list if you experience problems with the intersection operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Mirror

To mirror (reflect) geometry objects in a plane (3D), a line (2D), or a point (1D), in the **Geometry** toolbar, from the **Transforms** (☞) menu, select **Mirror** (⬇️). You can also right-click the **Geometry** node to add this node from the **Transforms** submenu. Then enter the properties of the mirror operation using the following sections:

INPUT

Select the geometry objects that you want to reflect in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Mirror** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

POINT ON PLANE/LINE OF REFLECTION

Specify a point to be fixed during reflection by entering **x**, **y**, and **z**.

NORMAL VECTOR TO PLANE/LINE OF REFLECTION

Specify a vector in the direction to reflect by entering **x**, **y**, and **z**.

POINT OF REFLECTION

For a 1D model, specify the coordinate of the point of reflection in the **x** field.

COORDINATE SYSTEM

The coordinate system in which the plane coordinates and normal vector above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the mirror operation).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Move

To move (translate) geometry objects, in the **Geometry** toolbar, from the **Transforms** () menu, select **Move** (). You can also right-click the **Geometry** node to add this node from the **Transforms** submenu. Then enter the properties of the move operation using the following sections:

INPUT

Select the geometry objects that you want to move in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Move** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

DISPLACEMENT

Set the displacement in each direction by entering **x**, **y**, and **z** (not all fields are available in 1D and 2D geometries); **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. To create several copies, enter a comma-separated or space-separated list of displacements in these fields, or click the **Range** button () to use the **Range** dialog box for specifying a range of displacements for moving multiple copies.

COORDINATE SYSTEM

The coordinate system in which the displacement coordinates above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the **Graphics** window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the displacement).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Parameter Check

You can add a **Parameter Check** node () to a geometry part or a geometry sequence to check the values of the input parameters (or local or global parameters). Such a check can be useful to make sure that a parameter value stays within a certain range, especially for input parameters to geometry s used in geometry models. The check gives an error if the condition that you provide is nonzero (true). For example, $r>30[\text{mm}]$ gives an error if the value of the parameter **r** exceeds 30 mm. Put the node at a position before the use of the parameter if you want the error to appear before using the parameter that you want to check when building a geometry feature. The error appears in an **Error** window and also as an **Error** subnode under the **Parameter Check** node. You enter the condition and error message in the following section:

PARAMETER CHECK

In the **Condition** field, type an expression in terms of the parameters (global, local, and input parameters). When you build the feature, an error occurs if the expression is nonzero.

In the **Error message** field, type an error message to display if the condition for the parameter check is nonzero.

Part Instance

Use a **Part Instance** node to call and instantiate a geometry part in the model component's geometry sequence. The geometry part can be a global part defined under one **Global>Parts** of a locally defined part. To create an instance of a geometry part, right-click a geometry and select one of the global parts from the **Parts** submenu. This adds a **Part Instance** node (, which builds an instance of the part with new values of its input parameters (arguments). Enter the properties of the part instance using the following sections:

PART

Choose the part to create an instance of from the **Part** list. You can choose among the parts defined under **Global>Parts**. You can also choose **Local part** (the default if no other parts exist), which means that the part is defined by the **Local Part** node ( in 3D) beneath the **Part Instance** node. To choose the part from the **Part Libraries**, click **Choose from Library**. You can then choose a part and click **Add to Geometry**. The part then also appears under **Global>Parts**.

INPUT PARAMETERS

The **Name** column of the table contains the input parameters required by the part. In the **Expression** column, enter the corresponding expressions. The expressions can contain parameters defined under **Global Definitions**. The defaults are the default expressions defined in the **Input Parameters** section for the part that you create an instance of. The values of the expressions appear in the **Value** column. The **Description** column contains the descriptions given by the part.

You can import or load data in files from a spreadsheet program, for example, with the **Load from file** button () and the **Load from File** dialog box that appears. Data must be separated by spaces or tabs. If the license includes LiveLink™ for Excel® you can also load input parameters from a Microsoft Excel Workbook spreadsheet.

POSITION AND ORIENTATION OF OUTPUT

Use this section to specify the translation and rotation to apply to the output objects (not in 1D).

In 3D, this transformation is done in two steps:

- The first step is to transform the output objects so that a chosen coordinate system from the part matches a given coordinate system defined by some feature preceding the Part Instance. Both coordinate systems are defined as the local coordinate system of a work plane. By default, the first step does nothing.
- The second step is to transform the output objects using a displacement and a rotation.

In 2D, only the second step of the transformation is available.

Coordinate system in part

Choose the coordinate system from the part in the **Work plane in part** list. You can choose among all work plane features in the part. You can also choose **xy-plane**, which corresponds to the global coordinate system (this is the default).

Coordinate system to match

To choose the coordinate system to match, first make a choice in the **Take work plane from** list. The default is **This sequence**, which means that you can select a work plane feature from this sequence. You can also choose another **Part Instance** above this one in the geometry sequence, which means that you take the work plane from the other

Part Instance node. In both cases, you select the work plane to match in the **Work plane** list. The default is **xy-plane**, which corresponds to the global coordinate system. The work plane to match is visualized in the graphics.

Displacement

Enter values or expressions for the **xw**, **yw**, and **zw** coordinates (SI unit: m) to add a displacement vector relative to the coordinate system to match.

Rotation

Select an **Axis type**: **xw-axis**, **yw-axis**, **zw-axis** (the default), **Cartesian**, or **Spherical**. For any choice, enter a **Rotation angle** (SI unit: degrees; default 0) to rotate the orientation of the output relative to the coordinate system to match.

If **Cartesian** is selected, enter Cartesian coordinates values for **xw**, **yw**, and **zw** (default values 0, 0, and 1 corresponding to the global *zw*-axis) to specify the axis vector. If **Spherical** is selected, specify the axis vector using spherical angles **theta** and **phi** in degrees.

Finally, specify a **Rotation angle** about the chosen axis in degrees.

In 2D, only the second step of the transformation is available. You can specify a displacement vector and a rotation angle.

OBJECT SELECTIONS

When you have built the Part Instance feature, the table shows the names of the output object selections that are defined by the part and there set to show in instances of the part. When you click a row in the table, the corresponding selection is highlighted in the graphics. These selections are available for use as input to following geometry features if kept, and also, optionally, available in the physics and materials, for example. You can unite selections from several **Part Instance** nodes using a cumulative selection. If you want a selection to contribute to a cumulative selection, choose that cumulative selection from the corresponding list in the **Contribute to** column. To contribute to a new cumulative selection, click the selection in the table and then the **New Cumulative Selection** button. This opens a dialog box where you can specify the name of the cumulative selection. Select the **Keep** check box to keep the selection for use in other nodes in the geometry sequence below this node.

DOMAIN/BOUNDARY/EDGE/POINT SELECTIONS

These sections are similar to the **Object Selections** section. If the **Keep** check box is selected, the **Physics (Instances** when used in another geometry part; **3D** when used in a plane geometry for a work plane) check box, when selected (which it is by default), makes that selection also available when defining, for example, physics and materials (Physics), in the part instances (**Instances**), or in 3D (**3D**).

SELECTION SETTINGS

Select the **Keep noncontributing selections** check box to disable the **Keep** column and keep all selections that do not contribute to a cumulative selection. This setting is the default in the COMSOL API and corresponds to the behavior in earlier COMSOL versions.

Partition Objects

The **Partition Objects** node () provides a way to partition geometry objects as a Boolean operation. Partitioning geometry objects can be useful to create separate domains, to introduce an interior boundary, or to cut off a part of the original geometry that is not needed for the analysis, for example. Using the **Partition Objects** node, you can partition a target object using a set of *tool objects* (geometry objects that are only used to partition — or tool — other geometry objects) or using an (infinite) plane defined by a **Work Plane** node (you do not need to draw anything in the work plane). The output of a **Partition Objects** node's partitioning operation includes the same number of objects as the input to the partitioning. To add it to a model, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Partition Objects**. You can also right-click the **Geometry** or a **Work Plane>Plane**

Geometry node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION OBJECTS

In the **Objects to partition** list, add the geometry objects that you want to apply a partition operation on. Click the **Active** button to toggle between turning ON and OFF the **Objects to partition** selections.

Select the **Keep objects to partition** check box to use the selected geometry objects to partition for further geometry operations.

From the **Partition with** list (3D only; for 2D, only objects can be used), select **Objects** (the default) to partition using the geometry objects that you add to the **Tool objects** list below, or select **Work plane** to partition using any of the added work planes.

- If you select **Objects**, add the geometry objects that you want to use as tool object to the **Tool objects** list. Click the **Active** button to toggle between turning ON and OFF the **Tool objects** selections. Those geometry objects are only used to partition the geometry objects in the **Objects to partition** list and are not included in the finalized geometry used for defining materials and physics nodes. Select the **Keep tool objects** check box to use the selected tool objects for further geometry operations.
- If you select **Work plane**, select from the available work planes in the **Work plane** list. Click the **Go to Source** button () to move to the **Work Plane** node for the selected work plane.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Partition Domains

The **Partition Domains** node () provides an operation that partitions selected domains at specified locations. You can specify the curves or surfaces for the partitioning in various ways (see the **Partition with** list information under **Partition Domains** below). Partitioning domains can be useful in cases where a structured mesh would be a better choice than an unstructured mesh but the domains are not suitable for a mapped or swept mesh. A **Partition Domains** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. The output of a **Partition Domains** node's partitioning operation includes the same number of geometry objects as the input to the partitioning. To add it to a 2D or 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** menu (), select **Partition Domains**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION DOMAINS

In the **Domains to partition** list, add the domains that you want to partition.

From the **Partition with** list in 2D, choose one of the following methods for defining the curves for partitioning the domains:

- Choose **Line segments between vertices** (the default) to define line segments using vertices (points) in the geometry, which you add to the **Vertices defining line segments** list.
- Choose **Lines through vertices** to define partitioning lines that pass through the vertices in the **Vertices defining lines** list. The lines through the vertices extend to the perimeters of the selected domains.
- Choose **Edges** to select edges in the geometry as the partitioning curves. Add the edges to use for partitioning to the **Edges** list.
- Choose **Extended edges** to use the lines and circles defined by straight and circular edges, respectively, as partitioning curves. Add the edges to use for partitioning to the **Straight or circular edges** list.
- Choose **Objects** to use geometry objects that you add to the **Objects** list for partitioning the domains. The objects used for partitioning remain for further geometry operations.

Using the **Vertices defining line segments** or **Vertices defining lines** list, it is possible to select any number of vertices (greater than 1). The operation automatically groups the selected vertices into pairs according to minimal distances and defines one partitioning line segment or line per pair.

From the **Partition with** list in 3D, choose one of the following methods for defining the surfaces for partitioning the domains:

- Choose **Work plane** (the default) to partition the domain using a work plane that you choose from the **Work plane** list. Click the **Go to Source** button () to move to the **Work Plane** node for the selected work plane.
- Choose **Faces** to select faces in the geometry as the partitioning faces. Add the faces to use for partitioning to the **Faces** list.
- Choose **Extended faces** to use the surfaces defined by planar, cylindrical, and spherical faces as partitioning surfaces. Add the faces to use for partitioning to the **Planar, cylindrical, or spherical faces** list.
- Choose **Objects** to use geometry objects that you add to the **Objects** list for partitioning the domains. The objects used for partitioning remain for further geometry operations. When **Objects** is selected, you can clear the **Keep objects** check box (selected by default) to not keep the objects use for the partitioning in the resulting geometry.

The **Objects** option in the **Partition with** list is not available if the **Partition Domains** node appears after the **Form Union/Assembly** node.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selections** check box to create predefined selections for all or some of domains, boundaries, edges, and points that the resulting objects consist of. Select **All levels**, **Domain selection** (the default), **Boundary selection**, **Edge selection** (3D only), **Point selection**, or **Off** from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list. These selections are available in all applicable selection lists under the physics, mesh, materials, and results branches but do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the selections contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list, or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Partition Edges

The **Partition Edges** node () provides an operation that partitions selected edges at specified locations. You can specify the positions by entering parameters based on the arc length or by selecting existing vertices whose orthogonal projections on the edges specify the positions. A **Partition Edges** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. To add it to a 2D or 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Partition Edges**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

EDGE SELECTION

In the **Edges to partition** list, add the edges that you want to partition. If you select multiple edges and multiple vertices, then the number of edges and the number of vertices must be the same.

POSITIONS

Specify the positions of the vertices used to project for the edge partitioning. From the **Type of specification** list, choose **Arc length** (the default) to add one or more parameters for the edge partitioning in the **Relative arc length parameters** list. The relative arc length parameters are scalar values between 0 and 1, providing relative arc length values of each edge that define the location of the partitioning vertices. Alternatively, choose **Vertex projection** to add vertices to the **Vertices to project** list. Then each edge for which the orthogonal projection of the vertex occurs in the interior is partitioned at the projection.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Partition Faces

The **Partition Faces** node () provides an operation that partitions selected faces at specified locations. You can specify the positions using curve segments between vertices, extended edges, or a work plane. A **Partition Faces** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. To add it to a 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Partition Faces**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION FACES

First select the faces to partition in the geometry. The faces appear in the list under **Faces to partition**.

From the **Partition with** list, choose one of the following methods for defining the curves for partitioning the faces:

- Choose **Curve segments between vertices** (the default) to select vertices adjacent to the faces to partition. Add the vertices to use for partitioning to the **Vertices defining curve segments** list. The faces to partition is then partitioned along the curves (lines) connecting the selected vertices.
- Choose **Work plane** to partition the faces using a work plane that you choose from the **Work plane** list. Click the **Go to Source** button () to move to the **Work Plane** node for the selected work plane.
- Choose **Extended edges** to partition the selected faces with extensions of adjacent edges by adding the edges to the **Planar edges** list.

Planar faces can only be partitioned by planar edges that are straight or circular while nonplanar faces can be partitioned by any type of planar edge.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .

- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Revolve

To revolve planar objects into 3D, right-click a geometry or a work plane node, and select **Revolve** (). Then enter the properties of the revolve operation.

GENERAL

From the **Revolve from** list, select **Faces** to revolve planar faces from the 3D geometry. Select the faces that you want to revolve in the Graphics window. These appear in the **Input faces** list. All selected faces must lie in the same plane.

Alternatively, from the **Revolve from** list, select **Work plane** to revolve objects from a work plane. In the **Work plane** list, select the work plane to revolve from. Select the objects that you want to revolve in the Graphics window. They appear in the **Input objects** list.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** or **Input faces** selections.

Select the **Unite with input objects** check box to unite the input objects with the revolved objects. Clear the **Unite with input objects** check box to keep the revolved objects separate from the input objects.

REVOLUTION ANGLES

Click the **Angles** button to specify the start angle (default: 0 degrees) and end angle (default value: 360 degrees; that is, a full revolution) of the revolution. If you click the **Full revolution** button you get a full revolution. This selection also enables the **Keep original faces** check box that controls if the original faces are kept in the revolved 3D geometry. Keeping these faces is necessary if you want to create a swept mesh. By default, COMSOL keeps such faces.

REVOLUTION AXIS

Select **2D** in the **Axis type** list to specify the revolution axis in the local coordinate system. When revolving work plane objects, the local coordinate system is defined by the work plane's coordinate system. When revolving planar

faces, the local coordinate system is defined by the face with the smallest face number in the first geometry object in the geometry sequence. Select **3D** in the **Axis type** list to specify the revolution axis in the 3D coordinate system.

POINT ON THE REVOLUTION AXIS

Specify a point on the revolution axis in the local coordinate system in the **xw** and **yw** fields. Alternatively, if **Axis type** is **3D**, specify a point on the revolution axis in the 3D coordinate system in the **x**, **y**, and **z** fields.

DIRECTION OF REVOLUTION AXIS

Specify a direction vector for the revolution axis in the local coordinate system in the **xw** and **yw** fields. Alternatively, if **Axis type** is **3D**, specify a direction vector for the revolution axis in the 3D coordinate system in the **x**, **y**, and **z** fields.

POLYGON RESOLUTION OF EDGES

This setting determines how accurately the edges in the revolution direction are represented. The resolution is the subdivision of the circle along which the 2D geometry is rotated.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Rotate

To rotate geometry objects, in the **Geometry** toolbar, from the **Transforms** () menu, select **Rotate** (). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the **Transforms** submenu. You can create one or multiple rotated copies with varying rotation angles. Then enter the properties of the rotate operation:

INPUT

Select the geometry objects that you want to rotate in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Rotate** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

ROTATION ANGLE

Specify the rotational angle in the **Rotation** field (default: 0 degrees). To get several rotated objects, enter a list of angles separated with commas or spaces or using the range function. Click the **Range** button () to define a range of angles using the **Range** dialog box. For example, `range(0,45,315)` creates eight objects, one at the original position and seven rotated copies at 45 degrees distance around a full 360 degrees circle.

CENTER OF ROTATION

Enter the center of the rotation in the **x** and **y** (for 2D) and **r** and **z** (in 2D axial symmetry) and 2D axisymmetric models for **xw** and **yw** in work planes fields.

POINT ON AXIS OF ROTATION

Enter a point on the rotation axis in the **x**, **y**, and **z** fields.

AXIS OF ROTATION

From the **Axis type** list, choose **x-axis**, **y-axis**, or **z-axis** (the default) to obtain an axis aligned with the specified coordinate axis. Choose **Cartesian** to enter a direction vector using the **x**, **y**, and **z** fields. Choose **Spherical** to enter the direction using the angles **theta** (polar, zenith) and **phi** (azimuth).

COORDINATE SYSTEM

The coordinate system in which the point coordinates and axis of rotation above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the rotation axis position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Scale

To scale geometry objects, in the **Geometry** toolbar, from the **Transforms** () menu, select **Scale** (). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the **Transforms** submenu. Then enter the properties of the scale operation using the following sections:

INPUT

Select the geometry objects that you want to scale in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Scale** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

SCALE FACTOR

By default, you get an isotropic scaling. Specify the scaling factor in the **Factor** field.

To get an anisotropic scaling, change **Scaling** to **Anisotropic**, and specify separate scale factors for the coordinate directions in the **x**, **y**, and (3D only) **z** fields; **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes.

CENTER OF SCALING

Specify the center point of the scaling by specifying **x**, **y**, and (3D only) **z**; **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. This is the point that stays fixed during the scaling (that is, the point that the scaled geometry objects approach when the scale factor goes to zero).

COORDINATE SYSTEM

The coordinate system in which the center of scaling coordinates above are interpreted (in 3D geometries only). From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the Graphics window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the center of scaling).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Split

The **Split** () operation splits an object into its entities:

- A solid splits into solids corresponding to its domains.
- A surface object splits into surface objects corresponding to its faces.
- A curve object splits into curve objects corresponding to its edges.

- A point object splits into point objects corresponding to its vertices.
- A general (mixed) object splits into solids (corresponding to the domains), surface objects (corresponding to faces not adjacent to a domain), curve objects (corresponding to edges not adjacent to a face or domain), and point objects (corresponding to vertices not adjacent to an edge, face, or domain).

To split geometry objects into their entities, in the **Geometry** toolbar, from the **Conversions** menu, select **Split** (). Then enter the properties of the split operation in the **Input** section.

INPUT

Select the geometry objects to split on in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Split** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)). From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Sweep

Select **Sweep** () from the **Geometry** toolbar to sweep one or several faces along a curve. Then enter the properties of the sweep operation using the following sections:

CROSS SECTION

Select the faces you want to sweep in the **Graphics** window. The faces appear in the **Faces to sweep** list. Click the **Active** button to toggle between turning ON and OFF the **Faces to sweep** selections.

Select the **Create cross-sectional faces** check box (active by default) to make the sweep operation create cross-sectional faces between the sweep sections. Such cross-sectional faces can be useful, for example, for a swept mesh where you want to specify the mesh distribution for each section of the sweep.

SPINE CURVE

Select the edges you want to sweep along in the **Graphics** window. More than one edge can be selected, but the selected edges must form a nonclosed connected chain. The edges appear in the **Edges to follow** list. Click the **Active** button to toggle between turning ON and OFF the **Edges to follow** selections.

Select the **Reverse direction** check box to sweep in the negative edge direction.

The **Smooth edge connections** check box is selected by default. Clearing this check box means that transition zones are not added, which can give a better result in cases where the original edges already connect with a continuous tangent.

From the **Parameterization** list, select one of the following options:

- **Arc length** (the default) to use a parameterization based on the arc length of the spine curve.
- **Normalized arc length** to use a similar parameterization but with a normalized arc length (values 0–1). If it is more suitable to express the scale factor and the twist angle using the original parameter, you can use the normalized arc length parameterization instead of the default arc length parameterization.
- **Internal** to use the parameterization that is stored in the geometry's data structures. This is the parameterization used in earlier versions of COMSOL Multiphysics. It can also be useful if the edge that you sweep along do not need a parameterization, or a parameterization is unsuitable for that edge.

KEEP INPUT

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

Select the **Include all inputs in finalize operation** check box to force the objects in the **Face to sweep** and **Edges to follow** lists to be included in the Form Union/Assembly operation. If the **Include all inputs in finalize operation** check box is not selected, these objects are not included in the Form Union/Assembly operation if the **Face to sweep** list or **Edges to follow** list contains all faces or edges in the objects.

MOTION OF CROSS SECTION

This section contains a number of properties that determine how the face is transformed when swept along the spine curve.

A curve parameter name can be defined in the **Parameter name** field. Use this parameter in the expressions defining scale factor and twist angle. The parameter is increasing along the chain of edges to follow. It is not the same as the parameter **s1** available in Results. For a single edge created by a Parametric Curve, the parameter is the same as the parameter used in the Parametric Curve.

The **Scale factor** field controls the size of the cross section face when swept along the spine curve.

The **Twist angle** field controls the rotation angle of the cross section face about the spine curve.

By default, twist compensation is active and prevents the twisting that would otherwise occur due to nonzero torsion for nonplanar curves. Clear the **Twist compensation** check box to turn off this compensation. When **Twist compensation** is active, it behaves as if a term was added to the **Twist angle** with a magnitude matching the integral of the torsion of the curve. This makes the edges in the sweep direction locally parallel to the spine curve. For a noncircular cross section, twist compensation also affects the shape of the generated object.

From the **Face-spine alignment** list, select an option to align the cross section to the spine curve:

- Select **No adjustment** (the default) to sweep the face starting from its original position. Using this setting, it is possible to create sweeps where the face is not perpendicular to the spine curve, and where the face does not contain that starting point of the spine curve.
- Select **Adjust spine** to adjust the spine curve so that it starts on the face to sweep and so that it is parallel to the face normal at the point where it touches the face. The first part of the spine curve is replaced by a cubic Bézier curve, with the length of the replaced part, measured in parameter values, controlled by the value in the **Adjustment parameter length** field.
- Select **Move face** to move the face to the start of the spine curve and orient the face perpendicularly to the spine curve. This setting is only allowed when the face is located in a work plane, and the movement is such that the work plane origin coincides with the spine curve.

ADVANCED SETTINGS

From the **Geometry representation** list, select **Spline** (the default) to represent the swept object using splines, or **Bézier**, to represent the swept object using Bézier curves. The difference is that using Bézier curves, the intersections between the surfaces that form the swept object are visible edges, whereas they are hidden when using splines.

The value in the **Relative tolerance** field is a relative tolerance that controls the accuracy of the geometric representation of the swept object. The geometric representation is an approximation, which is necessary because it is not possible to exactly represent a swept object using NURBS (nonuniform rational basis splines). The default value is 10^{-4} (0.01%).

Internally, the software represents the swept object by B-spline curves and surfaces, which are computed to approximate the mathematical definition of the swept surface. The number of knot points in the splines increases automatically until the approximation satisfies the tolerance specified in the **Relative tolerance** field or until it reaches the number of knots specified in the **Maximum number of knots** field (default value: 1000).

If more than one edge is selected in the **Edges to follow** list, the **Direction-defining edge** controls which edge is used to define the positive sweep direction. The **Direction-defining edge** is automatically set when the first edge is added to the **Edges to follow** list, so usually it does not have to be changed manually.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Tangent

To create a tangent (that is, a line segment tangential to a specified edge), in the **Geometry** toolbar, click **Tangent** (). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the tangent.

TANGENT

Select the edge you want to tangent in the **Graphics** window. Only one edge can be selected. The edge appears in the **Edge to tangent** list.

Click the **Active** button to toggle between turning ON and OFF the **Edge to tangent** selections.

Parameter start guess is a number between 0 and 1 that specifies where on the edge the expected point of tangency is located. The tangent returned is the first tangent found starting the search from the start guess.

Type of tangent specifies how the endpoint of the tangent is specified. There are three options: **Edge-edge**, **Edge-point**, and **Edge-coordinate**.

When the type is edge–edge, you use the **Graphics** window to select a second edge to tangent. The edge appears in the **Second edge to tangent** box. The line segment created is tangent to both edges. Use **Parameter start guess for second edge** to specify the start guess for the second edge, it is a number between 0 and 1. Click the **Active** button to toggle between turning ON and OFF the **Second edge to tangent** selections.

When the type is edge–point, you use the **Graphics** window to select a point in the geometry as a tangent’s endpoint. The point appears in the **Point** list.

When the type is edge–coordinate, manually specify the coordinates of the tangent’s endpoint.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry par; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Union

To create the union of geometry objects, in the **Geometry** toolbar, from the **Boolean and Partitions** () menu, select **Union** (). You can also right-click the **Geometry** node to add this node from the **Boolean and Partitions** submenu. Then enter the properties of the union operation.

UNION

Select the geometry object that you want to unite in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Union** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** check box to use the selected geometry objects for further geometry operations.

Create a geometry object without interior boundaries by clearing the **Keep interior boundaries** check box. This can be useful to simplify a geometry where the interior boundaries do not separate domains with different physics nodes or materials, for example.

You can change the settings for the **Repair tolerance** list if you experience problems with the union operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .

- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

Work Plane

To create a work plane for defining 2D objects in 3D (for example, for extruding a 2D object into a 3D object) or for defining the placement of the resulting objects of a Part Instance, in the **Geometry** toolbar, click **Work Plane** () or right-click a 3D **Geometry** node and select **Work Plane**. Then enter the properties defining the location of the work plane in the following sections of its **Settings** window.

Using Work Planes

PLANE DEFINITION

Plane Type

The layout of the **Work Plane** section depends on the selection in the **Plane type** list, where you select how to define the work plane. Choose one of the following types:

- | | |
|---|--|
| <ul style="list-style-type: none"> • Quick (the default) • Face parallel • Edge parallel • Edge angle | <ul style="list-style-type: none"> • Circle perpendicular • Vertices • Coordinates • Transformed |
|---|--|

Quick

In the **Plane** list, select one of the global coordinate planes *xy*, *yz*, *, *yx*, *zy*, or *xz*, denoting the first and second axes of the work plane's local coordinate system. Specify an offset using on of the following settings in the **Offset type** list:*

- **Distance** (the default) to define the distance from the coordinate plane in the third axis' direction using the **z-coordinate**, **x-coordinate**, or **y-coordinate** field (default value: 0; that is, no offset).
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then contains that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

Face parallel

Select a planar face in the **Graphics** window that is parallel to the work plane you want to create with the **Planar face** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected face. Click the **Active** button to toggle between turning ON and OFF the **Planar face** selections. Specify an offset using on of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. You then offset the work plane along the normal of the planar face. By default, the work plane's normal is the outward normal of the face in the **Planar face** list. The default value: 0; that is, no offset.
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

To reverse the direction of the *z*-axis of the work plane's coordinate system, select the **Reverse normal direction** check box. This also swaps the coordinate axes in the work plane to preserve the positive orientation of the local coordinate system.

Edge parallel

Select a planar edge (that is not straight) in the **Graphics** window that is parallel to the work plane you want to create with the **Planar curved edge** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected edge. Click the **Active** button to toggle between turning ON and OFF the **Planar curved edge** selections.

Specify an offset using on of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. You then offset the work plane along the normal of the plane containing the edge. The default value: 0; that is, no offset.
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

To reverse the direction of the *z*-axis of the work plane's coordinate system, select the **Reverse normal direction** check box. This also swaps the coordinate axes in the work plane to preserve the positive orientation of the local coordinate system.

Edge angle

Activate the **Straight edge** list by first selecting its **Active** button and then select a straight edge with the **Straight edge** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected edge. Similarly, activate the **Face adjacent to edge** list by first clicking its **Active** button and then select an adjacent face in the **Graphics** window or from the list. Also, specify a value in the **Angle between face and work plane** field (in degrees; the default value is 0). This results in a work plane through the given edge that makes the specified angle with the adjacent face.

By default, the origin of the local coordinate system coincides with the edge's start vertex, and the direction of the local *x*-axis coincides with the direction of the edge. If you select the **Reverse normal direction** check box, the origin instead is at the end vertex, and the normal direction of the local *x*-axis is reversed.

Circle perpendicular

Activate the **Circular edge** list by clicking its **Active** button. Then select a circular edge in the **Graphics** window. This results in a work plane perpendicular to the given circular edge. Use the **Point on plane** list to choose a vertex that the plane should go through:

- The edge's **Start vertex** (the default)
- The edge's **End vertex**.
- Some **Other vertex**, which you can choose from the **Vertex** list that opens.

You can then rotate the work plane around the normal direction of the circle's plane by specifying an **Angle offset** (in degrees; default value: 0 degrees). You can also reverse the work plane's normal direction using the **Reverse normal direction** check box.

The origin of the local coordinate system is at the circle's center. The local *x*-axis goes through the circle. Thus, if the geometry is rotationally symmetric, the symmetry axis coincides with the local *y*-axis. You can use this type of work plane together with a **Cross Section** node to get a 2D axisymmetric geometry corresponding to a rotationally symmetric 3D geometry.

Vertices

In each of the lists **First vertex**, **Second vertex**, and **Third vertex**, select a vertex by first clicking the corresponding **Active** button and then selecting a vertex in the **Graphics** window. This creates a work plane parallel to a plane through the three vertices.

Specify an offset in the **Offset in normal direction** field (default value: 0; that is, no offset). The origin of the local coordinate system is located above the first vertex, and the vector to the second vertex becomes the local *x*-axis. Reverse the directions of the local *z*-axis and *y*-axis by selecting the **Reverse normal direction** check box.

Coordinates

This choice creates a work plane through the three points with the given coordinates. The origin of the local coordinate system coincides with **Point 1**. The *x*-axis of the local coordinate system is in the direction of the vector from **Point 1** to **Point 2**. The positive direction of the *y*-axis is determined by the condition that the vector from **Point 1** to **Point 3** has a positive *y*-component.

Transformed

Use the work plane type to create a work plane using a transformation of another work plane. From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a geometry part that this geometry sequence calls earlier in the sequence. From the **Work plane to transform** list, select an available work plane (for example, **Work Plane 1 {wp1}**) from the selected geometry sequence or select **xy-plane** (the default).

Under **Displacement**, enter the desired displacements in the work plane's *x*-, *y*-, and *z*-directions in the **xw**, **yw**, and **zw** fields, respectively. The defaults are 0 (that is, no displacement).

Under **Rotation**, choose an axis for the rotation from the **Axis type** list:

- **xw-axis**, **yw-axis**, or **zw-axis** (the default) to use the local *x*-, *y*-, or *z*-axis.
- **Cartesian** to define an axis using local Cartesian coordinates in the **xw**, **yw**, and **zw** fields. The default values are 0, 0, and 1, respectively (that is, the same as choosing **zw-axis**).
- **Spherical** to define an axis using spherical angles (in degrees), which you enter in the **theta** and **phi** fields (default value for both angles: 0).

In the **Rotation angle** field enter the rotation angle (in degrees) about the specified axis (default: 0).

LOCAL COORDINATE SYSTEM

In this section you specify the local coordinate system in the work plane for most work plane types.

In the **Quick** work plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: **Global** (the default) or **Vertex projection**. In the latter case, also pick a vertex for the origin, which you add to the list under **Vertex for origin** (manually or by choosing an applicable geometry object or selection).
- In the **Local x-axis** list, choose how to define the local x -axis: **Natural** (the default), which means that the local x -axis corresponds to the first direction in the plane; for example, the y direction for a yz -plane. Alternatively, choose **Through vertex projection** to define the local x -axis through a vertex projection. Then choose a vertex for the local x -axis that you add to the **Vertex for axis** list (manually or by choosing an applicable geometry object or selection).

In the **Face parallel** plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: **Center of face** (the default), **Bounding box corner**, or **Vertex projection**. In the last case, choose a vertex for defining the origin that you add to the **Vertex for origin** list.
- In the **Local x-axis** list, choose how to define the local x -axis: **First parameter direction** (the default) or **Second parameter direction**, which are the local parameter directions of the face (represented by the variables $s1$ and $s2$, respectively). Alternatively, choose **Through vertex projection** to define the local x -axis through a vertex projection. Then choose a vertex for the local x -axis that you add to the **Vertex for axis** list.

In the **Edge parallel** plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: The **Start vertex** (the default) or **End vertex** of the edge, or **Vertex projection**. In the last case, choose a vertex for defining the origin that you add to the **Vertex for origin** list.
- In the **Local x-axis** list, choose how to define the local x -axis: **Tangent direction** (the default), which means that the local x -axis follows the direction of the edge's tangent. Alternatively, choose **Through vertex projection** to define the local x -axis through a vertex projection. Then choose a vertex for the local x -axis that you add to the **Vertex for axis** list.

In the **Quick**, **Face parallel**, **Edge parallel**, **Edge angle**, **Circle perpendicular**, and **Vertices** work plane types:

- Enter displacements within the plane in the **xw-displacement** and **yw-displacement** fields if you want to move the origin of the local coordinate system. The defaults are 0.
- Enter a rotation angle in the **Rotation** field if you want to rotate the local coordinate system. The default is 0 degrees; that is, no rotation.

UNITE OBJECTS

By default, the COMSOL Multiphysics software unites all objects in the 2D work plane, which can make it easier to, for example, extrude the 2D geometry into a 3D geometry object.

Clear the **Unite objects** check box if you do not want to unite the separate 2D geometry objects in the work plane. If the check box is selected, you can change the settings for the **Repair tolerance** list if you experience problems with the unite operation. Objects that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6} .

- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

PART INSTANCES

This section is only available for work planes in geometry parts.

Select the **Show work plane in instances** check box (selected by default) to make the work plane available in the **Part Instance** nodes' settings.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** check box to create predefined selections (for all levels — objects, domains, boundaries, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics (Show in instances** if in a geometry part) list: **All levels**, **Object selection** (in geometry parts only), **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See [Selection Colors](#).

Under **Selections from plane geometry**, select the **Show in physics (Show in instances** if in a geometry part) check box to show selections from the work plane's plane geometry in the physics or in part instances. For example, a selection in the plane geometry can be used as the boundaries for a boundary condition in the 3D physics.

Cumulative Selection

If you want to make the resulting entities that the 2D geometric objects in the work plane consist of contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see [Cumulative Selections](#)).

DRAWING IN THE WORK PLANE

To show the work plane, click the **Show Work Plane** button () in the **Settings** window's toolbar, or click the **Plane Geometry** node that appears under the **Work Plane** node. To create 2D objects in the work plane, right-click the **Plane Geometry** node and create nodes like in a 2D geometry.

EMBEDDING THE WORK PLANE IN THE 3D GEOMETRY

To embed the 2D work plane geometry in the 3D geometry, build the Work Plane feature by either right-clicking the **Work Plane** node and choosing **Build Selected** or selecting the **Work Plane** node and then clicking **Build Selected** or **Build All Objects**.

Using Work Planes

CREATING 3D GEOMETRIES FROM 2D WORK PLANES AND 3D FACES

In addition to creating 3D geometries directly using 3D geometric primitives, it is also possible to form 3D geometries based on 2D sections (2D geometries) created in work planes or faces in the existing 3D geometry. A *work plane* is a 2D plane oriented anywhere in the 3D space. Quick options make it easy to create a work plane that is parallel to any of the main Cartesian planes or to a face or edge in an existing 3D geometry.

There are several methods to create 3D solid objects from 2D sections or faces. In addition, you can use a 2D section as an “embedded” surface in the 3D geometry.

Drawing on a work plane works just as drawing in 2D. The 3D work plane adapts its size to the drawn geometry.

See *Electric Sensor* (model library path **COMSOL_Multiphysics/Electromagnetics/electric_sensor**). Use the instructions to practice building the geometry, which includes **Work Plane**, **Rectangle**, **Ellipse**, **Union**, **Compose**, **Extrude**, and **Block** features.

DRAWING ON A 2D WORK PLANE IN 3D

When using a **Work Plane** () node to define 2D objects in 3D (for example, to extrude into a 3D object), the 3D projection settings enable you to draw on the work plane in 3D. These instructions provide an example. When the **View work plane geometry in 3D** check box is selected in the **Settings** window for the **Plane Geometry** node () under the **Work Plane** node, two additional buttons are available in the **Graphics** window — the **Align with work plane** button () and the **Work plane clipping** button (). The standard 2D geometry draw toolbar is also available for use.

Some computer graphic cards cannot run the work plane rendering. In these cases, the work plane is rendered as a blue plane. It is possible to go to the 3D work plane but not to draw on the plane.

- 1 Add a 3D **Component** and then add a geometry (for example, a **Sphere**).
- 2 In the **Geometry** toolbar, click **Work Plane** (or right-click **Geometry** I and select **Work Plane**).
- 3 Under **Work Plane** click the **Plane Geometry** node.
- 4 Under **Visualization**, select the **View work plane geometry in 3D** check box. See [Figure 7-4](#) and [Figure 7-5](#) to see what happens when the check box is selected.
- 5 The geometry displays in the **Graphics** window. See [Figure 7-5](#) for an example.
 - Click the **Align with work plane** button () to rotate and move the camera to see the work plane from the top down.
 - Click to toggle the **Work plane clipping** button () on and off. When on, use it to cut away all geometries above the work plane and make it easier to draw when objects are overlapping within the work plane. The clipping is not done when looking at the work plane from the side.
- 6 Under **In-plane visualization of 3D geometry**, specify how to visualize 3D objects in the work plane (as blue curves and points) by selecting one or more of the following check boxes (all of them are selected by default):
 - **Coincident entities (blue)** — Show edges and points (in a pure blue color) that lie in the work plane.
 - **Intersection (cyan)** — Show the intersection of 3D geometry and the work plane (in cyan).
 - **Projection (light blue)** — Show the projection of all edges and points onto the work plane (in light blue).

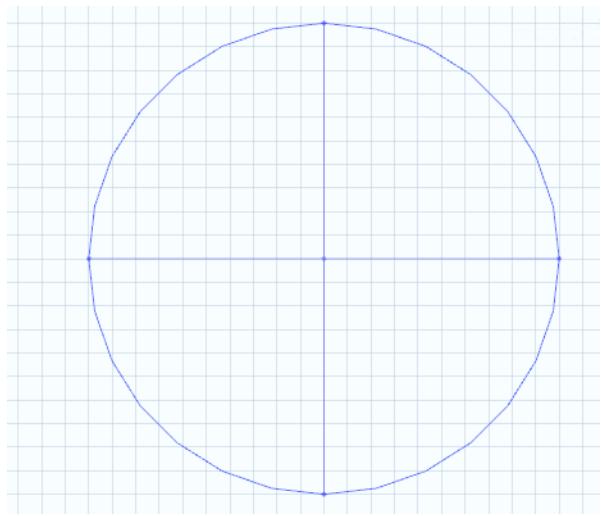

Figure 7-4: The Graphics window displaying the Work Plane Geometry when the View work plane geometry in 3D check box is not selected.

7

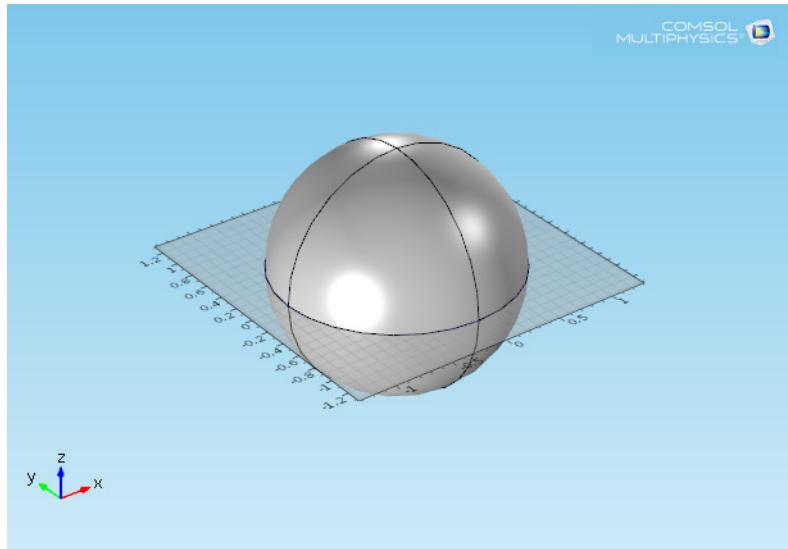

Figure 7-5: The Graphics window displaying the Work Plane Geometry with the View work plane geometry in 3D check box selected.

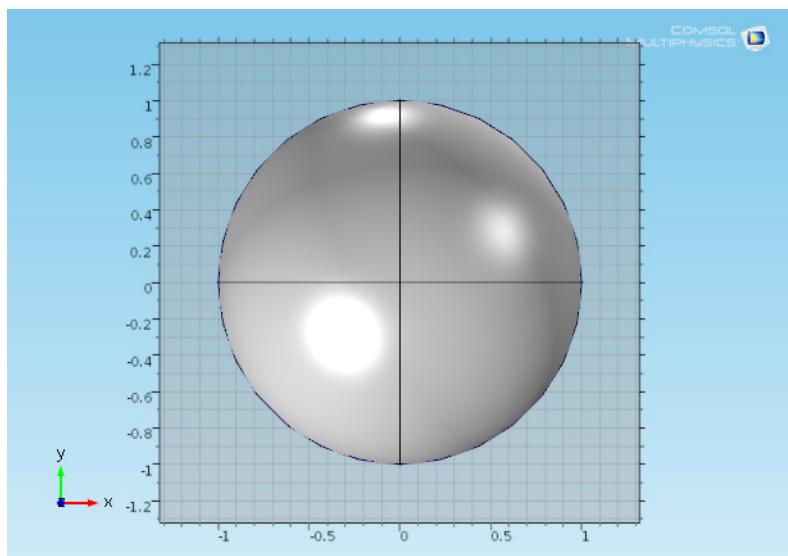

Figure 7-6: Click the Align with Work Plane button to display the geometry from the top down.

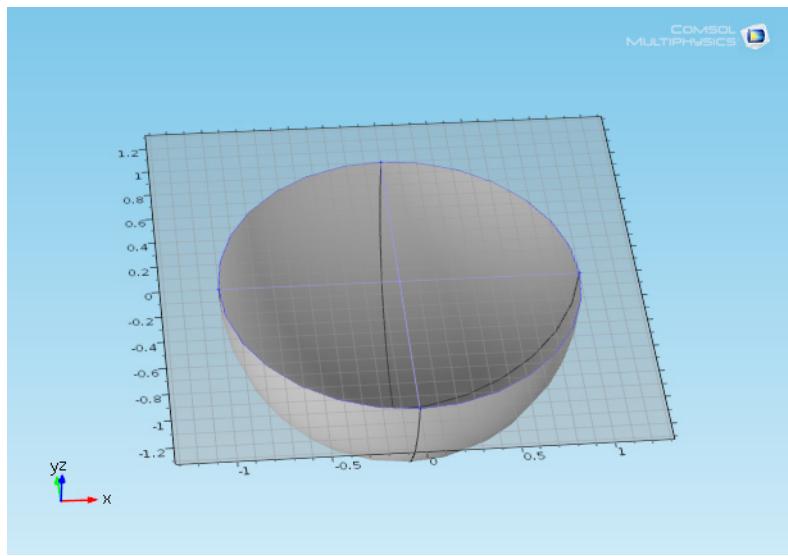

Figure 7-7: Click to turn on the Work Plane Clipping button and cut away all geometries above the work plane.

Virtual Geometry and Mesh Control Operations

Forming Composite Edges and Faces by Ignoring Vertices and Edges and Merging Vertices by Collapsing Edges

VIRTUAL GEOMETRY OPERATIONS

For a 2D or 3D geometry you can add *virtual geometry operations* after the **Form Union/Assembly** node to, for example, remove small details from the geometry and to prepare it for efficient meshing and analysis. The geometry sequence before the **Form Union/Assembly** node defines the “real” (original) geometry. The geometry resulting from a virtual operation is referred to as a *virtual geometry*.

Use the **Remove Details** feature to automatically remove small details from the geometry.

These virtual operations are available from the **Geometry** toolbar, **Virtual Operations** menu ():

TABLE 7-9: VIRTUAL OPERATIONS FOR 2D AND 3D MODELS

ICON	NAME	DESCRIPTION
	Remove Details	Removed details from the geometry automatically or by adding virtual subfeatures.
	Ignore Edges	Virtually remove isolated edges or edges adjacent to precisely two faces or between two domains
	Ignore Faces	Virtually remove isolated faces or faces between two domains (3D only)
	Ignore Vertices	Virtually remove isolated vertices or vertices adjacent to precisely two edges
	Form Composite Domains	Form virtual composite domains from sets of connected domains by ignoring the boundaries between the domains in each set
	Form Composite Edges	Form virtual composite edges from sets of connected edges by ignoring the vertices between the edges in each set
	Form Composite Faces	Form virtual composite faces from sets of connected faces by ignoring the edges between the faces in each set (3D only)
	Collapse Edges	Virtually collapse each edge into a vertex by merging its adjacent vertices
	Collapse Faces	Virtually collapse faces into edges or vertices by merging their adjacent opposite edges or collapsing all adjacent edges
	Collapse Face Regions	Virtually detect and collapse regions of faces narrower than a specified size
	Merge Edges	Virtually merge opposite edges adjacent to a face
	Merge Vertices	Virtually merge one adjacent vertex of an edge with the other adjacent vertex

MESH CONTROL OPERATIONS

The following mesh control operations are available from the **Geometry>Virtual Operations** menu () and can be used to include ignored geometric entities for mesh control purposes to, for example, make it possible to use a mapped mesh:

TABLE 7-10: MESH CONTROL OPERATIONS

ICON	NAME	DESCRIPTION
	Mesh Control Domains	To select domains for mesh control only.
	Mesh Control Edges	To use isolated edges, or edges adjacent to precisely two domains (in 2D) or two faces (in 3D), only for mesh control.
	Mesh Control Faces	To use isolated faces, or faces between two 3D domains, only for mesh control.
	Mesh Control Vertices	To use isolated vertices, or vertices adjacent to precisely two edges, only for mesh control.

Collapse Edges

To virtually collapse edges into vertices, in the **Geometry** toolbar, from the **Virtual Operations** menu (), select **Collapse Edges** (). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to collapse in the Graphics window. They then appear in the **Edges to collapse** list. If the geometry sequence includes user-defined selections above the **Collapse Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to collapse**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to collapse** selections.

Select the **Ignore merged vertices** check box to ignore the resulting merged vertices (if possible).

The operation collapses an edge by removing it, merging its adjacent vertices to the vertex with lowest index, and reconnecting the adjacent edges to the *merged vertex*.

The operation collapses the edges in the selection where no other edge shares the same adjacent vertices (unless this is in the selection).

Collapse Faces

To virtually collapse faces into edges or vertices, in the **Geometry** toolbar, from the **Virtual Operations** menu (), select **Collapse Faces** (). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to collapse in the Graphics window. They then appear in the **Faces to collapse** list. If the geometry sequence includes user-defined selections above the **Collapse Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to collapse**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to collapse** selections.

The operation collapses a face by removing it, merging its adjacent opposite edges or collapsing all adjacent edges, and reconnecting the adjacent faces to the resulting merged edges.

Select the **Ignore merged entities** check box to ignore the resulting merged edges or vertices (if possible).

By default, the **Collapse to vertex tolerance** list is set to **Automatic**. Select **Manual** to enter a value in the **Maximum face perimeter** field that appears. The default values is 0.001. This tolerance is the maximum perimeter of a face to be collapsed into a vertex.

Collapse Face Regions

To automatically detect and collapse regions of faces narrower than a specified size, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Collapse Face Regions** (). You can also select it from the **Geometry** node's context menu's **Virtual Operations** submenu. Such narrow regions of faces can cause unwanted mesh refinement or even meshing failure. The collapse face regions operation determines narrow regions of a face and then collapses those resulting sliver faces.

Enter the properties of the operation using the following sections:

INPUT

Select the faces for which you want to collapse narrow face regions in the **Graphics** window. They then appear in the **Faces** list. If the geometry sequence includes user-defined selections above the **Collapse Face Regions** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces**.

Click the **Active** button to toggle between turning ON and OFF the **Faces** selections.

By default, the **Narrow regions tolerance** list is set to **Automatic**. Select **Manual** to enter a value in the **Maximum width** field that appears. The tolerance is the maximum width of a face region to be considered as narrow. If you build the operation with **Automatic** and then switch to **Manual**, the **Maximum width** field shows the value of the parameter that was used when the operation was built.

Form Composite Domains

To form virtual composite domains, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Form Composite Domains** ( or ). Then enter the properties of the operation using the following sections:

INPUT

Select the domains that you want to composite in the **Graphics** window. They then appear in the **Domains to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Domains** node, choose **Manual** to select domains, or choose one of the selection nodes from the list next to **Domains to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Domains to composite** selections.

Use the **Ignore adjacent vertices** (2D) or **Ignore adjacent edges and vertices** (3D) check box to specify if the operation also removes the ignorable vertices (and edges in 3D) on the boundary of each resulting composite domain.

The operation forms a composite domain for each connected domain component of the selected domains by ignoring the boundaries between the domains.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected domains are composed in the geometry but are available individually when you build the mesh. This gives you more control of the meshing. A well partitioned geometry is more efficient to mesh and can, for example, make it possible to create a high quality hexahedral mesh through the sweep operations.

Form Composite Edges

To form virtual composite edges, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Form Composite Edges** (). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to composite in the **Graphics** window. They then appear in the **Edges to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to composite** selections.

The operation forms a composite edge for each connected edge component (of manifold type) of the selected edges by ignoring the vertices between the edges. However, it does not ignore vertices when that would introduce closed or periodic composite edges.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected edges are composed in the geometry but are available individually when you build the mesh.

Form Composite Faces

To form virtual composite faces, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Form Composite Faces** (). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to composite in the **Graphics** window. They then appear in the **Faces to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to composite** selections.

Use the **Ignore adjacent vertices** check box to specify if the operation also removes the ignorable vertices on the boundary of each resulting composite face.

The operation forms a composite face for each connected face component (of manifold type) of the selected faces by ignoring the edges between the faces.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected faces are composed in the geometry but are available individually when you build the mesh.

Ignore Edges

To remove isolated edges or edges adjacent to precisely two domains or two faces from the geometry, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Ignore Edges** (). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to ignore in the **Graphics** window. These then appear in the **Edges to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to ignore** selections.

Use the **Ignore adjacent vertices** check box to specify if the operation also removes the ignorable start and end vertices of the edges.

The operation removes the selected edges that are isolated or that are adjacent to precisely two faces or are between two domains.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected edges disappear from the geometry but become available when you build the mesh. You can, for example, use *mesh control edges* to control the element size inside a domain or to partition the geometry to use a mapped mesh. See also [Mesh Control Edges](#).

Ignore Faces

This operation is available for 3D models only.

To remove isolated faces or faces between two domains from the geometry, in the **Geometry** toolbar, from the **Virtual Operations** menu (), select **Ignore Faces** (). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to ignore in the **Graphics** window. They then appear in the **Faces to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to ignore** selections.

Use the **Ignore adjacent vertices and edges** check box to specify if the operation also removes the ignorable vertices and edges adjacent to the faces.

The operation removes the selected faces that are isolated or that are between two domains.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected faces disappear from the geometry but become available when you build the mesh. You can, for example, use a *mesh control face* to partition the geometry to make it possible to sweep a hexahedral mesh. See also [Mesh Control Faces](#).

Ignore Vertices

To remove isolated vertices or vertices adjacent to two edges only from the geometry, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Ignore Vertices** (). Then enter the properties of the operation using the following sections:

INPUT

Select the vertices (points) that you want to ignore in the **Graphics** window. These then appear in the **Vertices to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Vertices** node, choose **Manual** to select vertices, or choose one of the selection nodes from the list next to **Vertices to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Vertices to ignore** selections.

The operation removes the selected vertices that are isolated or that are adjacent to precisely two edges. However, it does not remove vertices if that would introduce closed or periodic *composite edges*.

MESH CONTROL

Use the **Keep input for mesh control** check box to specify that the selected vertices disappear from the geometry but become available when you build the mesh. You can, for example, use a *mesh control vertex* to control the element size inside a domain. See also [Mesh Control Vertices](#).

Merge Edges

To virtually merge opposite edges adjacent to a face, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Merge Edges** (). Then enter the properties of the operation using the following sections:

EDGES TO KEEP

Select the edges that you want to keep in the **Graphics** window. They then appear in the **Edges to keep** list.

Click the **Active** button to toggle between turning ON and OFF the **Edges to keep** selections.

EDGES TO REMOVE

Select the edges that you want to remove in the **Graphics** window. They then appear in the **Edges to remove** list.

Click the **Active** button to toggle between turning ON and OFF the **Edges to remove** selections.

The operation merges the opposite edges by collapsing the face between the edges and reconnecting the faces adjacent to the removed edges to the resulting merged edges.

Merge Vertices

To virtually merge one vertex adjacent to an edge with the other adjacent vertex, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Merge Vertices** (). Then enter the properties of the operation using the following sections:

VERTEX TO KEEP

Select the vertex that you want to keep in the **Graphics** window. It then appears in the **Vertex to keep** list.

Click the **Active** button to toggle between turning ON and OFF the **Vertex to keep** selections.

VERTEX TO REMOVE

Select the vertex that you want to remove in the **Graphics** window. It then appears in the **Vertex to remove** list. Click the **Active** button to toggle between turning ON and OFF the **Vertex to remove** selections.

The operation merges the two vertices by collapsing the edge between the vertices and reconnecting the edges adjacent to the removed vertex to the resulting merged vertex.

Mesh Control Domains

To use a domain only for mesh control, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Mesh Control Domains** (). Then enter the properties of the operation using the following sections:

INPUT

Select the domains that you want to use for mesh control in the Graphics window. They then appear in the **Domains to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Domains** node, choose **Manual** to select domains, or choose one of the selection nodes from the list next to **Domains to include**.

Click the **Active** button to toggle between turning ON and OFF the **Domains to include** selections.

The operation removes the selected domains by composing them with adjacent domains. The faces (3D only) and edges in between are removed from the geometry but become available when you build the mesh. You can, for example, use a *mesh control domain* to partition the geometry to make it possible to sweep a hexahedral mesh.

Mesh Control Edges

To use isolated edges, or edges adjacent to precisely two domains (in 2D) or two faces (in 3D), only for mesh control, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Mesh Control Edges** (). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to use for mesh control in the **Graphics** window. They then appear in the **Edges to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to include**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to include** selections.

Use the **Include adjacent vertices** check box to specify if the operation also include the ignorable start and end vertices of the edge.

The operation removes the selected edges that are isolated or that are adjacent to precisely two faces (in 3D) or two domains (in 2D). The edges are removed from the geometry but become available when you build the mesh. You can, for example, use a *mesh control edge* to control the element size inside a domain or to partition the geometry to make use of a mapped mesh.

[Ignore Edges](#)

Mesh Control Faces

To use isolated faces, or faces between two 3D domains, only for mesh control, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Mesh Control Faces** (). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to use for mesh control in the **Graphics** window. They then appear in the **Face to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to include**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to include** selections.

Use the **Include adjacent vertices and edges** check box to specify if the operation also includes the ignorable vertices and edges adjacent to of the faces.

The operation removes the selected faces that are isolated or that are between two domains. The faces are removed from the geometry but become available when you build the mesh. You can, for example, use a *mesh control face* to partition the geometry to make it possible to sweep a hexahedral mesh.

[Ignore Faces](#)

Mesh Control Vertices

To use isolated vertices, or vertices adjacent to precisely two edges, only for mesh control, in the **Geometry** toolbar, from the **Virtual Operations** menu () , select **Mesh Control Vertices** (). Then enter the properties of the operation using the following sections:

INPUT

Select the vertices (points) that you want to use for mesh control in the **Graphics** window. They then appear in the **Vertices to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Vertices** node, choose **Manual** to select vertices, or choose one of the selection nodes from the list next to **Vertices to include**.

Click the **Active** button to toggle between turning ON and OFF active **Vertices to include** selections.

The operation removes the selected vertices that are isolated or that are adjacent to precisely two edges. However, it does not remove vertices if that would introduce closed or periodic *composite edges*. The selected vertices are removed from the geometry but become available when you build the mesh. You can, for example, use a *mesh control vertex* to control the element size inside a domain.

Ignore Vertices

Remove Details

From the **Virtual Operations** menu in the context menu when right-clicking a 3D **Geometry** node or directly from the **Geometry** ribbon toolbar, choose **Remove Details** (✖) to add a node with settings for automatically remove small details from the geometry. Small details include short edges and small and narrow (sliver) faces, which may complicate the meshing and make the model more difficult to solve. The **Settings** window contains the following sections:

AUTOMATION

The default in the **Mode of operation** list is **Automatic**. Typically, use the automatic mode first. The **Remove Details** operation generates and builds a local sequence of virtual operations. You can then switch to **Manual** if needed to inspect the added virtual operations and fine-tune and add more such operations. When you have built the **Remove Details** node and the **Mode of operation** list is set to **Manual**, the created virtual operations are available as subnodes to the **Remove Details** node. Alternatively, right-click the **Remove Details** node and choose **Edit Generated Sequence** (✎). You can also then right-click the **Remove Details** node to add more virtual operations. If you want to restore the generated sequence of virtual operations, choose **Reset to the Generated Sequence** (↻) from the **Remove Details** node's context menu.

The following sections are only available when the **Mode of operation** list is set to **Automatic**.

ENTITIES TO PROCESS

The default is to remove small details from the entire geometry. From the **Entities** list, choose **Selection** instead of **Entire geometry** to make a selection of entities for which you want to remove small details.

If you choose **Selection**, the **Geometric entity level** list appears with the options **Domain** (the default), **Boundary**, and **Edge**. If the geometry sequence includes user-defined selections, you can choose one of them from the **Selection** list; otherwise, or if you choose **Manual** from the **Selection** list, select entities from the **Graphics** window or by pasting selections into the list of selected entities.

DETAILS TO REMOVE

This section contains the following check boxes that specifies what type of repair issues to address:

- **Vertices with continuous tangent**: This check box controls whether each vertex that is adjacent to two edges with C1 continuity across the vertex, and that is not isolated in any face, is ignored.
- **Short edges**
- **Small faces**

- **Sliver faces**
- **Thin domains.** When this check box is selected, the software automatically removes domains with a thickness less than the specified detail size (see below).

	Not all types of details to remove are always applicable, depending on the chosen geometric entity level. For example, the Thin domains check box is only applicable if the selection is the entire geometry or a domain selection.
---	--

All check boxes are selected by default. When the remove details operation has finished, information about the number of removed details appears in the table under **Information**.

PARAMETERS

In this section you can control the parameters that determine the size of details to remove.

From the **Detail size** list, choose **Automatic** (the default), **Relative**, or **Absolute**. If you choose **Relative** the **Maximum relative size** field appears (default value: 0.001). If you select **Absolute**, the **Maximum absolute size** field appears (default value: 0.001 times the size of the geometry's bounding box). When you build this feature, the **Maximum relative size** and the **Maximum absolute size** are set to the values that are used, which can be useful when you have set **Detail size** to **Automatic**.

The values in the **Continuous tangent tolerance** field (default value: 5 degrees) specifies the maximum allowed angular tangent deviation across a vertex or edge to be ignored.

INFORMATION

This section contains information about the removed details: In the **Type of removal** column, the types of details that have been removed are listed. In the **Removed entities** column, the number of entities for each type of remove operation is listed.

Click **Build Selected** () (or press F7) to build the geometry up to and including this node, click **Build Preceding** () (or press F6) to build the geometry up to the node preceding this node, or click **Build All** () (or press F8) to build all nodes in the geometry sequence.

Geometry Modeling Examples

Creating a 2D Geometry Model

This section describes how to build a 2D cross section of a heat sink and introduces 2D geometry operations in COMSOL Multiphysics.

Assume that you want to estimate the maximum amount of heat dissipated by a heat sink placed around a resistor for high-power applications. The heat sink consists of an extruded aluminum profile as in [Figure 7-8](#). If the effects at the ends of the elongated heat sink are neglected, the model can be simplified and a decent estimate obtained of the heat dissipated by creating a 2D cross section.

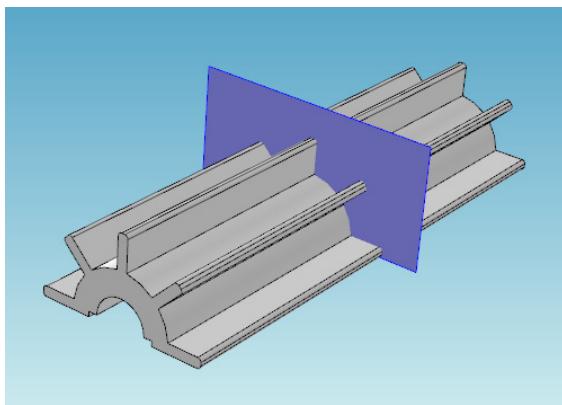

Figure 7-8: Example of a 3D heat sink model with cross section.

CREATING A BASIC 2D GEOMETRY MODEL

- 1 Double-click the COMSOL Multiphysics icon to launch COMSOL.
- 2 Add a **2D Component**, either when [Creating a New Model](#) or adding [The Component Node](#).

CREATING PARAMETERS FOR GEOMETRY PARAMETERIZATION

The following steps explain how to create two circles to form the core of the heat sink in [Figure 7-8](#). To investigate different dimensions of the heat sink, parameterize the geometry. Start by defining the radius of the outer arc of the heat sink, the radius of the inner arc, and the thickness and the length of the heat sink flanges.

See [Toolbars and Keyboard Shortcuts](#) for links and information about all the available toolbars.

Also see [The COMSOL Desktop Menus and Toolbars](#).

It is also useful to review [Working with Geometric Entities](#) and [Creating Named Selections](#) before continuing with these instructions.

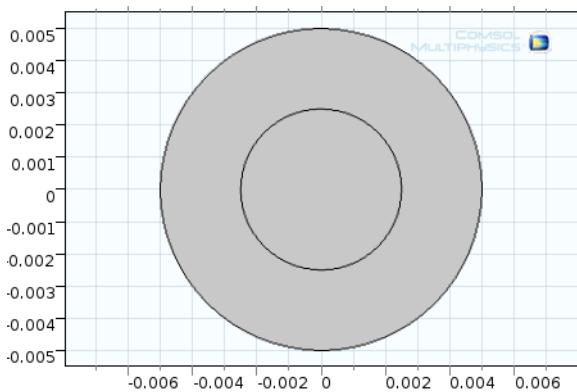

- 1 In the **Home** toolbar, click **Parameters** ().
- 2 In the **Parameters** table, enter, or copy and paste the values in the table below. The **Value** column automatically displays the **Expression** value.

NAME	EXPRESSION	DESCRIPTION
R1	5[mm]	Radius circle 1
R2	2.5[mm]	Radius circle 2

NAME	EXPRESSION	DESCRIPTION
d	1[mm]	Height
L	5[mm]	Width

ADDING TWO CIRCLES WITH PREDEFINED PARAMETERS

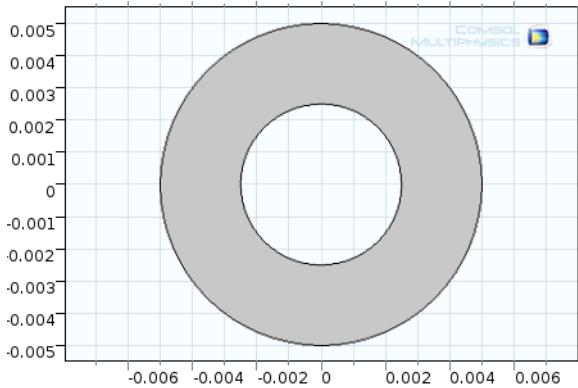

- 1 Under **Component 1**, right-click the **Geometry 1** node and choose **Circle** ().
- 2 On the **Settings** window for **Circle** under **Size and Shape**, enter R1 in the **Radius** field.
- 3 Click the **Build Selected** button ().
A circle (c1) with radius R1 displays in the **Graphics** window.
- 4 Add another circle. Right-click **Geometry 1** and select **Circle** ().
- 5 On the **Settings** window for **Circle** under **Size and Shape**, enter R2 in the **Radius** field.
- 6 Click the **Build Selected** button ().
A circle with radius R2 displays in the **Graphics** window. Click the **Zoom Extents** button () to see both circles.

SUBTRACTING THE SMALLER CIRCLE

- 1 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Difference** ().
- 2 In the **Settings** window, under **Difference**, the **Active** button is **On** () by default. It activates the **Objects to add** list for choosing objects.
- 3 In the **Graphics** window, click to select object **c1** (the larger circle). **c1** is added to the **Objects to add** list.
- 4 Under **Objects to subtract** click the **Active** button to toggle  and activate this section.
- 5 Select the object **c2** (the smaller circle). This can be done by clicking it in the **Graphics** window. Or open the **Selection List** window (from the **Home** toolbar, **More Windows>Selection List**) and right-click **c2 (solid)** to **Add to Selection**.

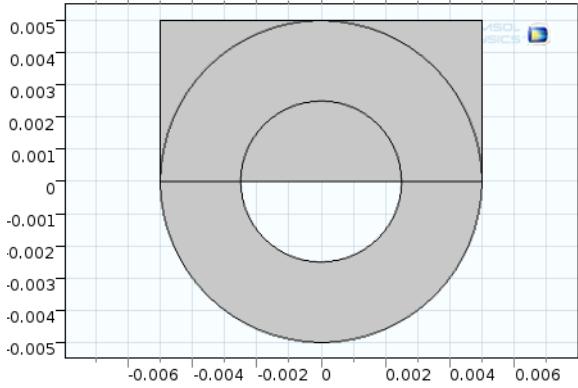

- 6 Click the **Build Selected** button (). The object **dif1** is created by subtracting the smaller circle from the larger circle.

INTERSECTING WITH RECTANGLE

- 1 Under **Component 1**, right-click the **Geometry 1** node and choose **Rectangle** ().
- 2 On the **Settings** window for **Rectangle**, under **Size**:
 - a In the **Width** field enter $2*R1$, and in the **Height** field, enter $R1$.
 - b Under **Position**, enter $-R1$ in the **x** field.
- 3 Click the **Build Selected** button ().

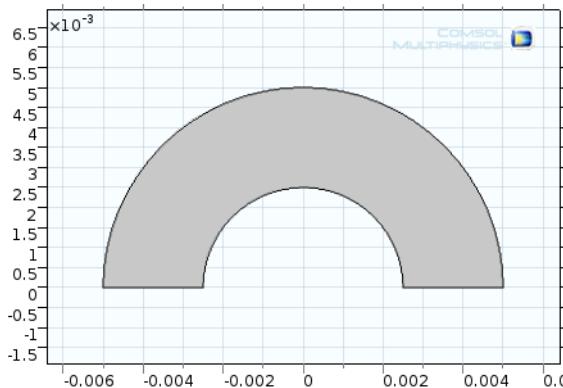

The interaction operation creates the object **r1** (not related to the circle radius), which coincides with the intersecting area of the two input objects.

- 4 Click the **Geometry 1** node. In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Intersection** ().
- 5 In the **Graphics** window click to select each object — **dif1** (the combined circle) and **r1** (the rectangle).

After each click, the object is added to the **Input Objects** list.

- 6 Click the **Build Selected** button () to create the object int1.

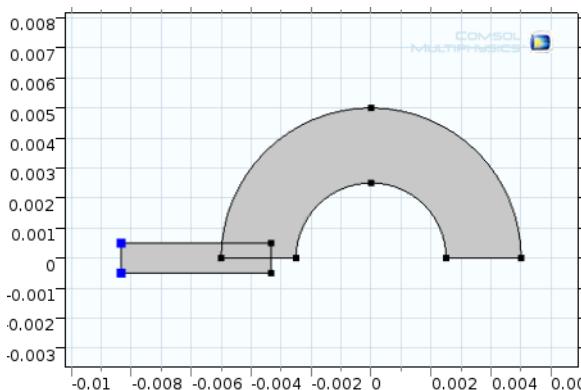

ADDING A RECTANGLE TO CREATE A FLANGE

- 1 Right-click the **Geometry 1** node and choose **Rectangle** ().
- 2 On the **Settings** window for **Rectangle** under **Size**:
 - a In the **Width** field, enter L.
 - b In the **Height** field, enter d.
- 3 Under **Position**, in the **x** field enter $-(2/3*R1+L)$, and in the **y** field enter $-d/2$.
- 4 Click the **Build Selected** button (). On the **Graphics** window toolbar, click the **Zoom Extents** button ().

The object r2 (not related to the circle radius) is created. Next, round the sharp edges of the flange by using fillets.

ADDING A FILLET TO ROUND THE FLANGE EDGES

- 1 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Fillet** ().
- 2 On object r2 (the small rectangle) click each vertex (**1** and **4**, located in the left-hand corners, highlighted in blue in the figure) to add these to the selection lists.

- 3 On the **Settings** window for **Fillet** under **Radius**, enter $d/3$ in the **Radius** field.
- 4 Click the **Build Selected** button () to create object fil1.

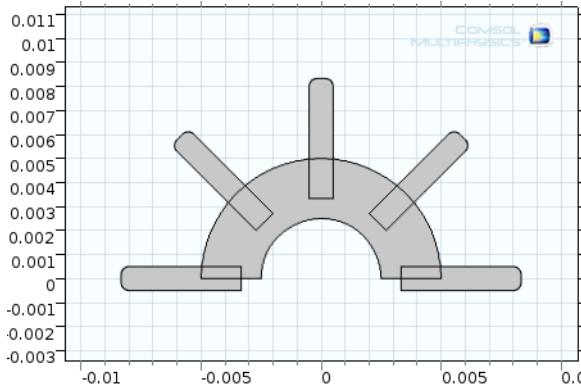

ADDING ROTATE OPERATIONS TO CREATE FIVE FLANGES

Rotate the flange 45 degrees and keep the original input object to create five flanges on top of the heat sink.

Adding Rotate 1 to Create Object Rot1

- 1 In the **Geometry** toolbar, from the **Transforms** menu, select **Rotate** ().

- In the **Graphics** window, click to select object **fil1** (the filleted rectangle). It is added to the **Input objects** list.
- On the **Settings** window for **Rotate** under **Input**, select the **Keep input objects** check box.
- Under **Rotation Angle**, enter **-45 -90 -135 -180** in the **Rotation** field.
- Click **Build Selected** () to create the object **rot1**. Click **Zoom Extents**().

REMOVING INTERIOR BOUNDARIES IN UNION OPERATIONS

- In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- In the **Graphics** window click the objects **int1**, **fil1**, **rot1(1)**, **rot1(2)**, **rot1(3)**, and **rot1(4)**. These are added to the **Input objects** section (or click the **Select All** button () in the **Graphics** toolbar).
- In the **Settings** window for **Union**, click to clear the **Keep interior boundaries** check box to remove the interior boundaries in the union operation. This is good practice if these boundaries do not define separate parts with different materials, for example.
- Click the **Build All Objects** button (). Click the **Zoom Extents** button (). The final geometry is shown in Figure 7-9.

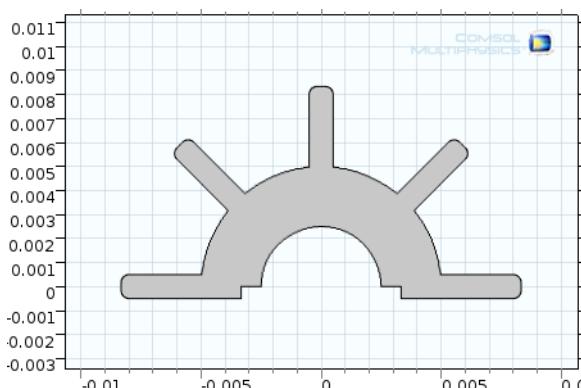

Figure 7-9: Final 2D object created in the Model Builder.

VIEWING THE GEOMETRY SEQUENCE

Figure 7-10 shows the geometry sequence used to create Figure 7-9. All primitive objects and the fillet operation are parameterized through the radius of the inner and outer heat sink arcs, the length and thickness of the flanges, and the radius of the fillets. You can change the parameter values in the **Parameters** table or for any object to create alternative heat sink geometries. The sequence still remains, and when you click the **Build All** button (), a new geometry is created.

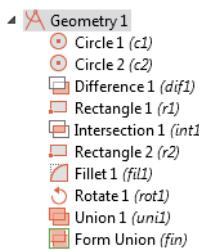

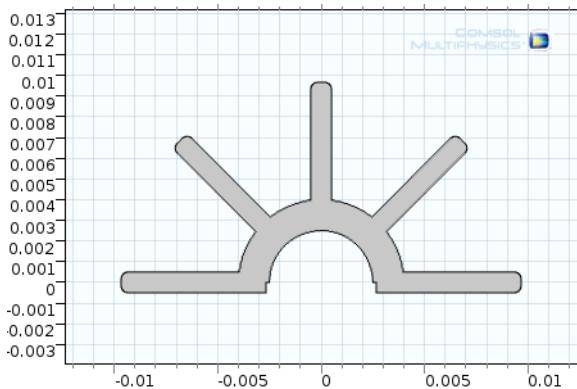

Figure 7-10: An example of a 2D geometry sequence.

RE-RUNNING THE GEOMETRY SEQUENCE WITH DIFFERENT PARAMETERS

- 1 In the **Home** toolbar, click **Parameters** () (or click the **Parameters** node under **Global Definitions**).
- 2 In the **Settings** window under **Parameters**, enter these settings in the table. Replace the previous data::

NAME	EXPRESSION	VALUE	DESCRIPTION
R1	4 [mm]	0.0040 m	Radius Circle 1
R2	2.5 [mm]	0.0025 m	Radius Circle 2
d	1 [mm]	0.0010 m	Height
L	7 [mm]	0.0070 m	Width

- 3 In the **Model Builder** click **Geometry 1**.
- 4 Click the **Build All** button (). Click the **Zoom Extents** button () to view the geometry as defined by the new parameters.

Creating a 3D Geometry Model

Figure 7-11 shows the geometry of a heat sink used for cooling microprocessors. The following sections describe the steps to create this geometry and introduces 3D drawing tools and techniques.

 See [Toolbars and Keyboard Shortcuts](#) for links and information about all the available toolbars.
Also see [The COMSOL Desktop Menus and Toolbars](#).

It is also useful to review [Working with Geometric Entities](#) and [Creating Named Selections](#) before continuing with these instructions.

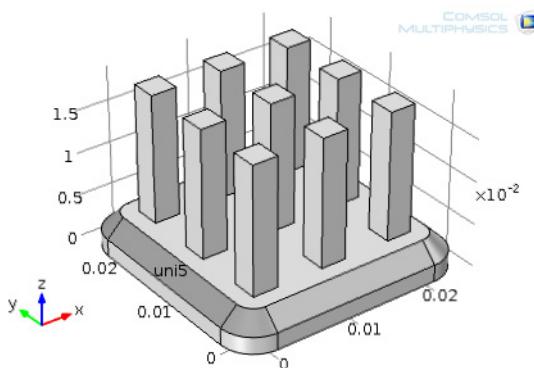

Figure 7-11: Example of a 3D heat sink geometry.

CREATING A BASIC 3D GEOMETRY COMPONENT

- 1 Double-click the COMSOL Multiphysics icon to launch COMSOL.
- 2 Add a **3D Component**, either when [Creating a New Model](#) or adding [The Component Node](#).

CREATING PARAMETERS FOR GEOMETRY PARAMETERIZATION

- 1 In the **Home** toolbar click **Parameters** ().
- 2 In the **Settings** window, in the **Parameters** table, enter these settings:

NAME	EXPRESSION	VALUE	DESCRIPTION
L1	1.5e-2	0.015	Pillar thickness (in the heat sink)
L2	3e-3	0.0030	Pillar length (in the heat sink)

USING WORK PLANES TO CREATE A BÉZIER POLYGON

Use work planes to create 2D geometries that you can extrude or revolve to create 3D objects.

Work Plane and Using Work Planes

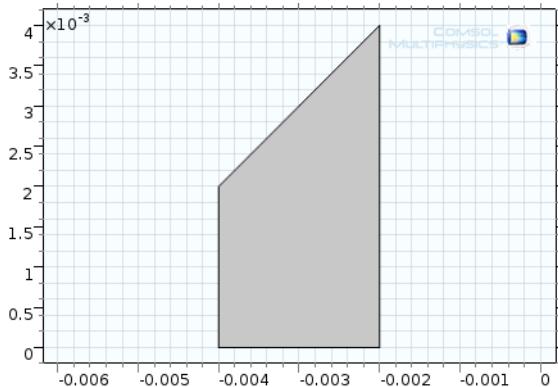

Creating a Bézier Polygon

- 1 In the **Geometry** toolbar click **Work Plane** ().
- 2 In the **Settings** window for **Work Plane** under **Plane Definition**, select **xz-plane** from the **Plane** list.
- 3 Under the **Work Plane 1** node, right-click **Plane Geometry** and add a **Bézier Polygon** () (or click **Plane Geometry** and on the **Work Plane** toolbar from the **Primitives** menu, select **Bézier Polygon**).
- 4 In the **Settings** window for **Bézier Polygon** under **Polygon Segments**, click **Add Linear**.
Segment 1 (linear) displays in the **Added segments** list.
- 5 Under **Control points**: In row **1**, enter $-2e-3$ in the **xw** field, and in row **2**, enter $-4e-3$ in the **xw** field.
- 6 Click **Add Linear** to add **Segment 2 (linear)** to the **Added segments** list. Some of the **Control points** are automatically filled in with values; the control points from the previous line are already filled in as the starting points for the next line.
- 7 Under **Control points**, in row **2**, enter $2e-3$ in the **yw** field.
- 8 Click **Add Linear** to add **Segment 3 (linear)** to the **Added segments** list.
- 9 In the **xw** field for row **2**, enter $-2e-3$. In the **yw** field for row **2**, enter $4e-3$.

I0 Click **Add Linear** to add **Segment 4 (linear)** to the **Added segments** list.

II Under **Control points** in the **yw** field for row 2, enter 0.

I2 Click **Close Curve**, then click the **Build Selected** button () and the **Zoom Extents** button ().

REVOLVING A 2D OBJECT TO CREATE A 3D OBJECT

1 Click the **Geometry 1** node. In the **Geometry** toolbar, click **Revolve** ().

The **Settings** window for **Revolve** opens and the 2D Bézier Polygon displays in the **Graphics** window.

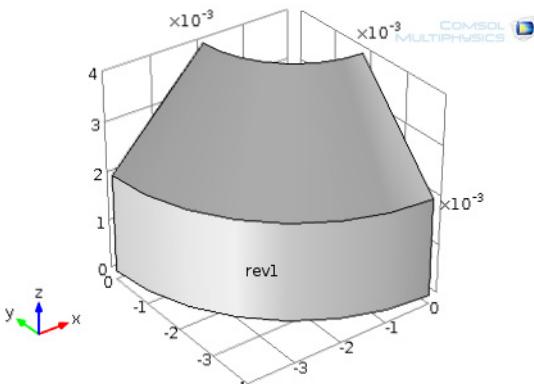

2 In the **Settings** window for **Revolve** under **Revolution Angles**, enter 90 in the **End angle** field (replace the default).

The **Revolution Axis** corresponds to the position of the **y**-axis in the work plane's 2D coordinate system.

3 Under **General**, click to clear the **Unite with input objects** check box. **Work Plane 1** is required for the next steps.

4 Click the **Build Selected** button () and the **Zoom Extents** button () to view the object **rev1**.

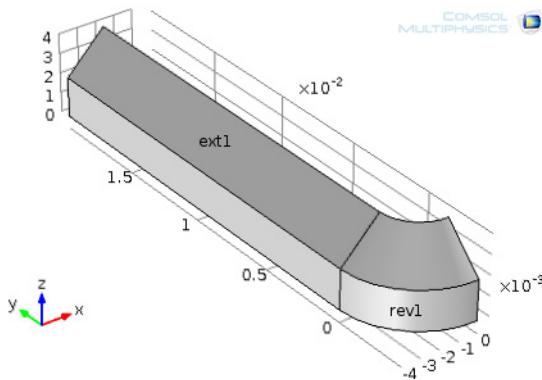

ADDING AN EXTRUSION AND UNION

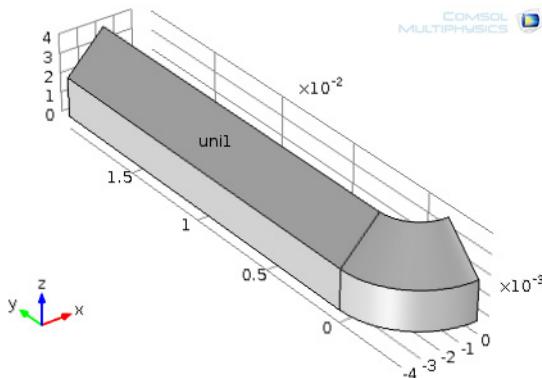

1 In the **Geometry** toolbar, click **Extrude** ().

2 In the **Settings** window, under **Distances from Plane**, enter $-2e-2$ in the **Distances** row.

3 Click the **Build Selected** button () and the **Zoom Extents** button () to view the object **ext1**.

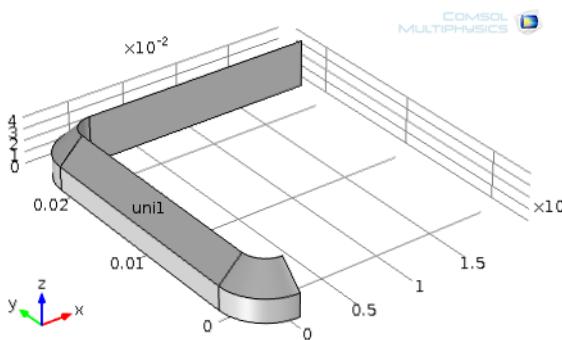

- 4 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- 5 In the **Graphics** window, click to select the objects **rev1** and **ext1** and add them to the **Input objects** section.
- 6 In the **Settings** window under **Union**, click to clear the **Keep interior boundaries** check box to remove the interior boundary between the corner section and the edge section.
- 7 Click the **Build Selected** button (). Objects **rev1** and **ext1** are combined to create object **unil**.

ADDING A ROTATION TO THE 3D OBJECT

- 1 Click **Geometry 1** and in the **Geometry** toolbar, from the **Transforms** menu, select **Rotate** ().
- 2 Select the object **unil** and add it to the **Input objects** section under **Input**.
- 3 Select the **Keep input objects** check box to leave the input object intact as a rotation of the object is created.
- 4 Under **Rotation Angle**, enter **-90** in the **Rotation** field.
- 5 Under **Point on Axis of Rotation**: In the **x** field, enter **1e-2**, and in the **y** field, enter **1e-2**.
- 6 Click the **Build Selected** button () and the **Zoom Extents** button () to view the object **rot1**.

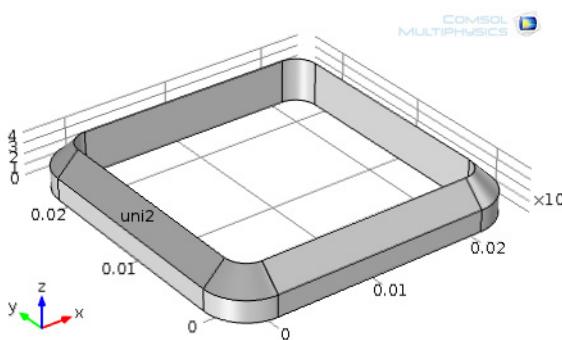

CREATING UNION 2

- 1 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- 2 In the **Graphics** window click to select the objects **uni1** and **rot1** and add them to the **Input objects** section under **Union**.
- 3 Click to clear the **Keep interior boundaries** check box.
- 4 Click the **Build Selected** button () to create object **uni2**.

ADDING A SECOND ROTATION

- 1 In the **Geometry** toolbar, from the **Transforms** menu, select **Rotate** ().
- 2 In the **Graphics** window, click to select the object **uni2** and add it to the **Input objects** section under **Input**.
- 3 In the **Settings** window for **Rotate**, click to select the **Keep input objects** check box.
- 4 Under **Rotation Angle**, enter -180 in the **Rotation** field.
- 5 Under **Point on Axis of Rotation**: In the **x** field, enter 1e-2, and in the **y** field, enter 1e-2.
- 6 Click the **Build Selected** button ().

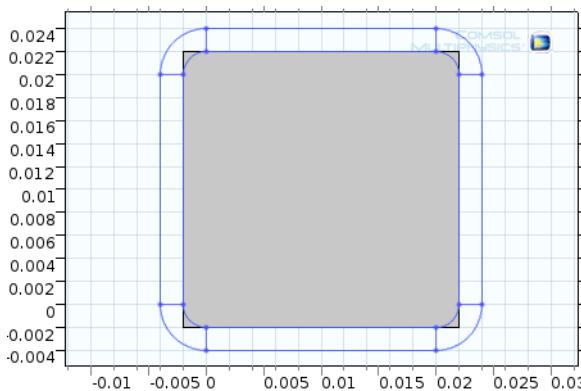

CREATING UNION 3

- 1 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- 2 In the **Graphics** window, click to select the objects **uni2** and **rot2** and add them to the **Input objects** section under **Union**.
- 3 Click to clear the **Keep interior boundaries** check box.

- Click the **Build Selected** button () to create object **uni3**.

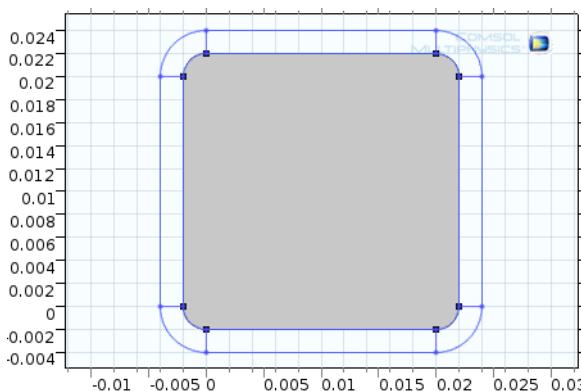

CREATING WORK PLANE 2 AND ADDING A SQUARE

- In the **Geometry** toolbar, click **Work Plane** (). A **Work Plane 2** node is added to the **Model Builder**.
- Click the **Build Selected** button ().
- In the **Settings** window for **Work Plane 2**, in the upper-left corner, click the **Show Work Plane** button (). Use the projection of the 3D geometry on the **xy**-plane as a guide for creating the middle section of the heat sink base.
- In the **Model Builder**, under **Work Plane 2**, right-click **Plane Geometry** and select **Square** ().
- In the **Settings** window for **Square** under **Size**, enter **2.4e-2** in the **Side length** field.
- Under **Position**, select **Center** from the **Base** list. Then in the **xw** field, enter **1e-2**, and in the **yw** field, enter **1e-2**.
- Click the **Build Selected** button () and the **Zoom Extents** button ().

TRIMMING THE SQUARE TO FIT USING THE FILLET OPERATION

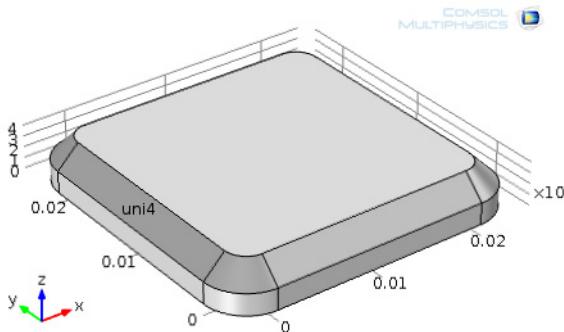

- Under **Work Plane 2**, click the **Plane Geometry** node.
- In the **Work Plane Modal Toolbar**, click **Fillet** ().
- In the **Graphics** window click to add points 1, 2, 3, and 4 on the object **sq1** to the **Vertices to fillet** section under **Points**.
- Under **Radius**, enter **2e-3** in the **Radius** field.
- Click the **Build Selected** button ().

ADDING EXTRUDE 2 AND COMBINING OBJECTS TO COMPLETE THE BASE

- Click the **Geometry 1** node. Then in the **Geometry** toolbar, click **Extrude** ().

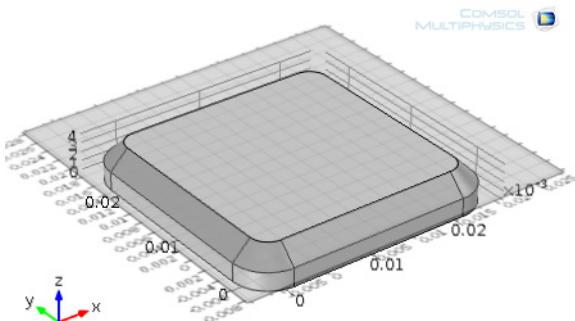

- 2 In the **Settings** window for **Extrude** under **Distances from Plane**, enter $4e-3$ in the **Distances** row.
- 3 Click the **Build Selected** button ().
- 4 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- 5 In the **Graphics** window, click to select the objects **uni3** and **ext2** to add to the **Input objects** section.
- 6 Click the **Build Selected** button () to create object **uni4**. This completes the base of the heat sink.

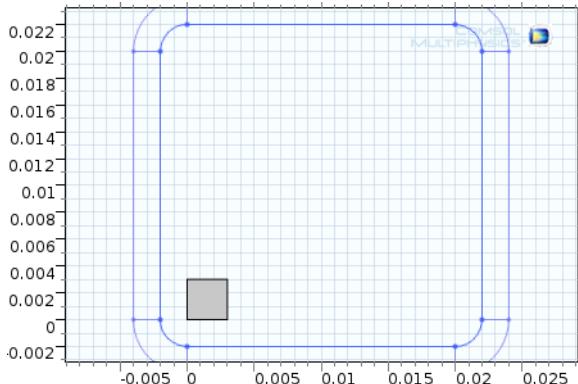

DRAWING THE UPPER PART OF THE HEAT SINK

Creating a Work Plane and a Square

- 1 In the **Geometry** toolbar, click **Work Plane** (). A **Work Plane 3** node is added to the **Model Builder**.
- 2 In the **Settings** window, under **Plane Definition**, enter $4e-3$ in the **z-coordinate** field.
- 3 Click the **Plane Geometry** node under **Work Plane 3**. In the **Settings** window, the check boxes **Coincident entities**, **Intersection**, and **Projection** are selected by default. This visualizes the projected edges of the heat sink's base in the work plane.
- 4 In the **Settings** window for **Work Plane**, click the **Build Selected** button ().

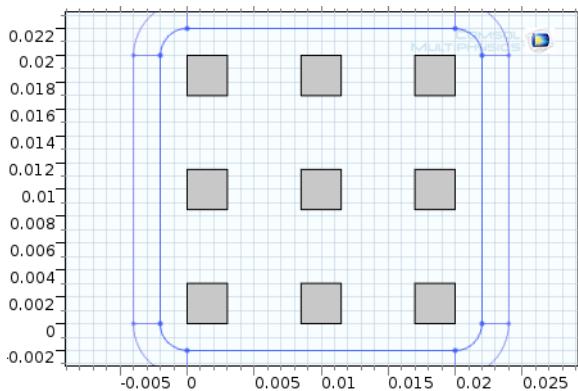

- 5 In the **Settings** window, click the **Show Work Plane** button ().
- 6 In the **Model Builder**, under **Work Plane 3**, right-click **Plane Geometry** and select **Square** ().
- 7 Under **Size**, enter **L2** in the **Side length** field.
- 8 Click the **Build Selected** button () to create square **sq1** with side length **L2**.

ADDING AN ARRAY OF PILLARS

- 1 Under **Work Plane 3** click **Plane Geometry**. On the **Work Plane** toolbar, from the **Transforms** menu, select **Array** ().
- 2 Add the object **sql** to the **Input objects** section under **Input**.
- 3 Under **Size**, in the **xw size** field, enter 3, and in the **yw size** field, enter 3.
- 4 Under **Displacement**, in the **xw** field, enter **1e-2-L2/2**, and in the **yw** field, enter **1e-2-L2/2**.
- 5 Click the **Build Selected** button ().

Adding Extrude 3 and Combining Objects (Union)

- 1 Click the **Geometry 1** node. Then in the **Geometry** toolbar, click **Extrude** ().
- 2 In the **Settings** window for **Extrude** under **Distances from Plane**, enter **L1** in the **Distances** row.
- 3 Click the **Build Selected** button () and the **Zoom Extents** button ().
- 4 In the **Geometry** toolbar, from the **Booleans and Partitions** menu, select **Union** ().
- 5 In the **Graphics** toolbar, click the **Select All** button () to add all the objects (**uni4** and all the **ext3** just built) to the **Input objects** list under **Union**.
- 6 Click the **Build All Objects** button () to complete the heat sink geometry as in [Figure 7-11](#).

The upper part of the heat sink is parameterized through the thickness and height of the heat sink pillars. You can edit the parameter values defined previously to change the heat sink geometry.

RE-RUNNING THE GEOMETRY SEQUENCE WITH DIFFERENT PARAMETERS

- 1 In the **Home** toolbar, click **Parameters** ().

2 In the **Settings** window under **Parameters** enter the following settings in the table. Replace the previous data:

NAME	EXPRESSION	VALUE	DESCRIPTION
L1	1.2e-2	0.012	Pillar thickness (in the heat sink)
L2	2e-3	0.0020	Pillar length (in the heat sink)

3 In the **Model Builder**, click **Geometry 1**.

4 Click the **Build All** button () and the **Zoom Extents** button () to view the geometry as defined by the new parameters.

Forming Composite Edges and Faces by Ignoring Vertices and Edges

This example of how to use virtual geometry operations shows how to use the [Ignore Vertices](#) operation (or the [Form Composite Edges](#) operation) to remove a very short edge and how to use the [Ignore Edges](#) operation (or the [Form Composite Faces](#) operation) to prepare the geometry for swept meshing.

GEOMETRY 1

1 Add a **3D Component**, either when [Creating a New Model](#) or adding [The Component Node](#).

2 In the **Home** toolbar, click **Import** ().

3 In the **Settings** window under **Import**, select **COMSOL Multiphysics file** from the **Geometry import** list.

4 Click **Browse**.

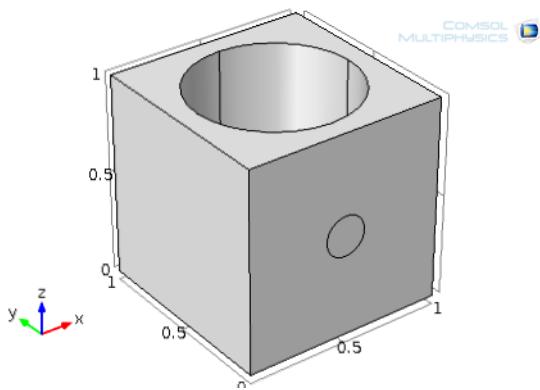

5 In the COMSOL installation directory navigate to the folder
applications/COMSOL_Multiphysics/Tutorials and double-click virtualgeom_demo_1.mphbin.

The location of the file varies based on the installation. For example, if the installation is on your hard drive, the file path might be similar to C:\Program Files\COMSOL\COMSOL54\Multiphysics\applications (in Windows).

6 Click **Import**. In the **Home** toolbar, click **Build All** ().

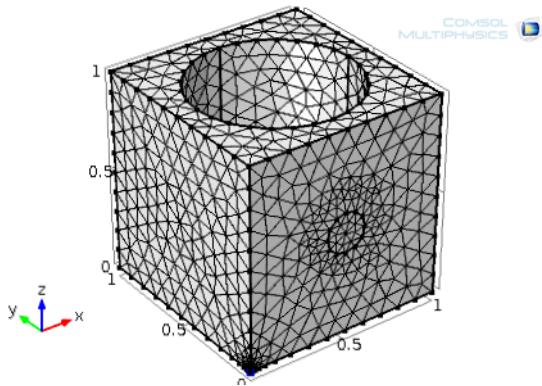

The imported geometry displays in the **Graphics** window.

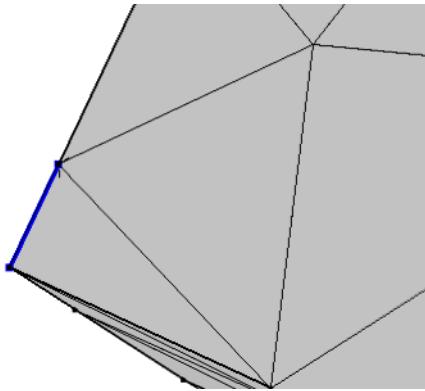

MESH 1

In the **Model Builder**, click the **Mesh** node. In the **Mesh** toolbar, click **Build All** ().

The resulting mesh displays in the **Graphics** window.

A **Warning** node () is added under **Mesh 1** indicating that there is a very short edge in the geometry. Use the **Zoom Box** button () and the **Zoom to Selected** button () in the **Graphics** toolbar to locate this edge.

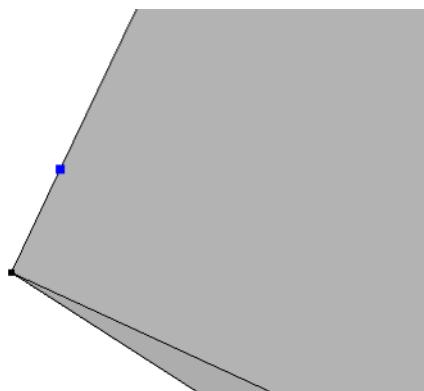

Eliminate the short edge by ignoring the vertex between this edge and its adjacent longer edge.

GEOOMETRY I

Ignore Vertices 1

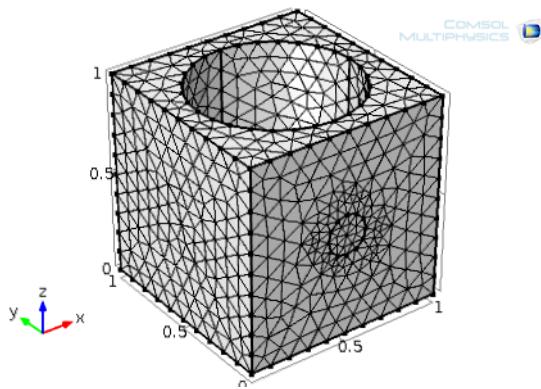

- 1 In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Ignore Vertices** ().
- 2 In the **Graphics** window click to select Point 3.

3 Click **Build Selected** ().

MESH I

In the **Model Builder**, click **Mesh I** and on the **Settings** window, click **Build All** (). The mesh displays in the **Graphics** window.

The geometry's domain is well suited for swept meshing.

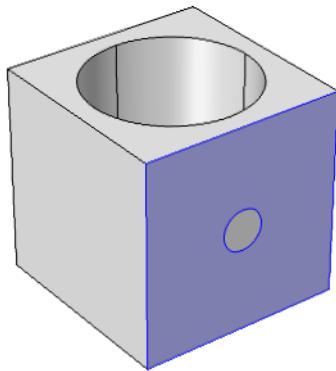

Swept I

- 1 In the **Mesh** toolbar, click **Swept** ().
- 2 In the **Settings** window for **Swept**, click to expand the **Source Faces** section.
- 3 The **Active** button is  by default. In the **Graphics** window click to select Boundary 3. Or click the **Paste** button () and enter 3.
- 4 Click to expand the **Destination Faces** section. The **Active** button is  by default. Click to select Boundary 4.

Size

- 1 In the **Model Builder**, click the **Size** node ().
- 2 In the **Settings** window for **Size** under **Element Size**, choose **Finer** from the **Predefined** list.
- 3 Click the **Build All** button ().

- 4** A **COMSOL Error** window opens indicating it **Failed to create swept mesh for domain**. Click **OK** to close the window. The COMSOL Multiphysics software fails to create a swept mesh due to the circular imprint on one of the linking faces of the sweep.

Use the [Ignore Edges](#) operation to remove this imprint.

G E O M E T R Y I

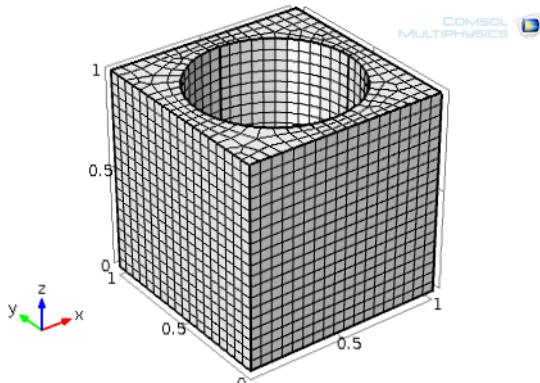

Ignore Edges /

- 1** In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Ignore Edges** ().
- 2** In the **Graphics** window, select Edges 14 and 15. Or click the **Paste** button and enter 14, 15.
The **Ignore adjacent vertices** check box is selected by default so that the vertices of the imprint disappear as well.
- 3** Click the **Build Selected** button ().

M E S H I

Click the **Mesh I** node and click **Build All** () in the **Settings** window.

The swept mesh displays in the **Graphics** window.

You can achieve the same virtual geometry using [Form Composite Edges](#) and [Form Composite Faces](#) operations.

G E O M E T R Y I

Disable

- 1** In the **Model Builder**, right-click **Ignore Edges I** and choose **Disable** ().

2 Click **Ignore Vertices I** and press F3. This also applies the **Disable** command.

Form Composite Edges I

1 In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Form Composite Edges** ().

2 Select Edges 2 and 6.

3 Click the **Build Selected** button ().

Form Composite Faces I

1 In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Form Composite Faces** ().

2 Select Boundaries 2 and 8.

3 Click the **Build Selected** button ().

MESH I

Click the **Mesh I** node and click **Build All** () in the **Settings** window.

Merging Vertices by Collapsing Edges

This example of virtual geometry operations illustrates how you can use the [Collapse Edges](#) operation (or the [Merge Vertices](#) operation) to prepare the geometry for efficient meshing.

GEOMETRY I

1 Add a **3D Component**, either when [Creating a New Model](#) or adding [The Component Node](#).

2 In the **Home** toolbar, click **Import** ().

3 In the **Settings** window for **Import**, under the **Import** section, click **Browse**.

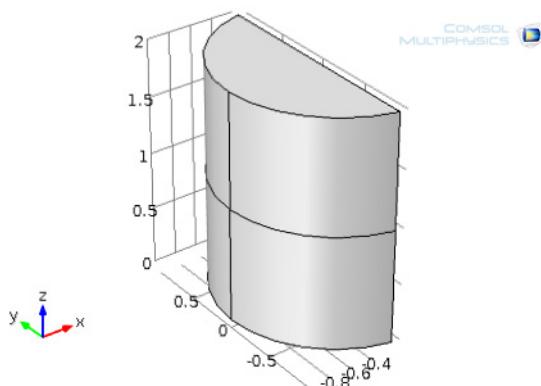

4 In the COMSOL installation directory, navigate to the folder
`applications/COMSOL_Multiphysics/Tutorials` and double-click `virtualgeom_demo_2.mphbin`.

The location of the file varies based on the installation. For example, if the installation is on your hard drive, the file path might be similar to
`C:\Program Files\COMSOL\COMSOL54\Multiphysics\applications` (in Windows).

5 Click **Import**.

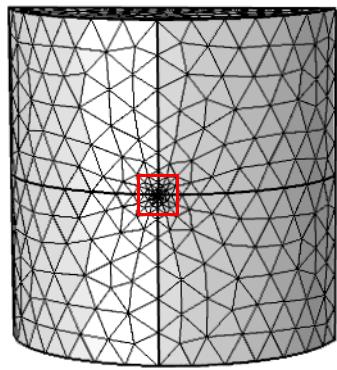

The imported geometry displays in the **Graphics** window.

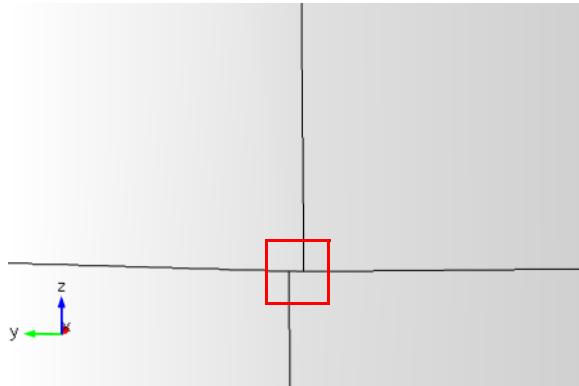

GEOMETRY I

In the **Model Builder** click **Mesh I**. In the **Settings** window, click **Build All** ().

The resulting mesh displays in the **Graphics** window.

The figure shows that the mesh is very fine in the region marked by the red box. To zoom into this region, click the **Geometry 1** node in the **Model Builder**. In the **Graphics** window, click the **Zoom In** button () and zoom into this region. You can then see the reason for the fine mesh. There is a very short edge at the junction of the four curved faces.

Remove this short edge by collapsing it into a vertex.

Collapse Edges 1

- 1 In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Collapse Edges** ().
- 2 Select Edge 4.

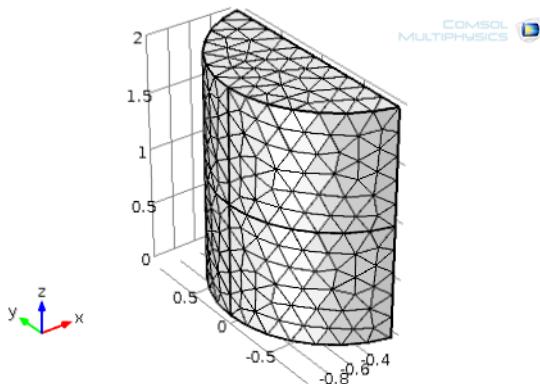

3 Click the **Build Selected** button ().

You can also remove this short edge with an [Ignore Edges](#) operation forming a composite face of the two adjacent faces. However, then the small distance between the vertices of the ignored edge remains.

MESH I

In the **Model Builder**, click **Mesh I**. In the **Settings** window, click **Build All** (). The mesh displays in the **Graphics** window. Click the **Go to View** button () on the **Graphics** window.

You can achieve the same virtual geometry using a [Merge Vertices](#) operation.

GEOMETRY I

Right-click **Collapse Edges I** and choose **Disable** ().

Merge Vertices I

1 In the **Geometry** toolbar, from the **Virtual Operations** menu, select **Merge Vertices** ().

2 Select Point 2.

3 Go to the **Settings** window for **Merge Vertices**. Locate the **Vertex to Remove** section and select Point 3.

4 Click the **Build Selected** button ().

MESH I

In the **Model Builder** click **Mesh I**. In the **Settings** window, click **Build All** ().

8

Meshing

This chapter describes meshing capabilities, meshing techniques, and meshing operations available for meshing the geometry.

In this chapter:

- [Creating a Mesh for Analysis](#)
- [Meshing Techniques](#)
- [Meshing Operations and Attributes](#)
- [Importing and Exporting Meshes](#)
- [Meshing Examples](#)

Creating a Mesh for Analysis

- [Meshing Concepts](#)
- [Mesh Elements for 1D, 2D, and 3D Geometries](#)
- [Free \(Unstructured\) Meshing](#)
- [Structured Meshes](#)
- [About Swept Meshes](#)

- [The Mesh Toolbar](#)
- [Adding, Editing, and Building Meshing Sequences](#)
- [Using Mesh Parts](#)
- [Mesh Part Settings](#)
- [Meshes Generated by Adaptation](#)
- [The Mesh Statistics Window](#)

Meshing Concepts

The **Mesh** () nodes enable the discretization of the geometry into small units of simple shapes, referred to as *mesh elements*.

A mesh is the result of building a meshing sequence. A meshing sequence corresponding to a geometry consists of [Meshing Operations and Attributes](#). The attribute nodes store properties that are used by the operation nodes when creating the mesh.

Building an operation node creates or modifies the mesh on the part of the geometry defined by the operation node's selection. Some of the operation nodes use properties defined by attribute nodes; for example, the [Free Tetrahedral](#) node reads properties from the [Distribution](#) and [Size](#) attribute nodes. If you choose to import a mesh you have access to a different set of operations (see [Operations on Imported Meshes](#)).

For some operation nodes, you can right-click to add local attribute nodes as subnodes. Properties defined in local attribute nodes of an operation node override the corresponding properties defined in global attribute nodes (on the same selection).

GLOBAL VS. LOCAL ATTRIBUTE NODES

An attribute node contains properties defined on a selection. You can add an attribute as a node in the meshing sequence (this is referred to as a *global attribute node*) or add it as a node under an operation node (a *local attribute node*). Global attribute nodes are used by operation nodes when building the meshing sequence. Local attribute nodes are only used by the owning operation node.

VISUALIZING THE MESH

The [Graphics Window](#) shows the resulting mesh from the nodes that have been built. The result of subsequent nodes is not visible. The last built node becomes the *current node* and appears with a quadratic frame around the node's icon (). The frame is green if the node and all preceding nodes are built; that is, the mesh in the Graphics window is up to date. The frame is yellow if the node or some preceding node has been edited since the node was built and needs to be rebuilt ().

Mesh Element Numbering Conventions in the *COMSOL Multiphysics Programming Reference Manual*.

1D GEOMETRIES

The mesh generator discretizes the domains (intervals) into smaller intervals (or mesh elements). The endpoints of the mesh elements are called *mesh vertices*.

The boundaries (or vertices) defined in the geometry are represented in the mesh by *boundary elements* (or *vertex elements*).

2D GEOMETRIES

The mesh generator discretizes the domains into *triangular* or *quadrilateral* mesh elements. If the boundary is curved, these elements represent an approximation of the original geometry. The sides of the triangles and quadrilaterals are called *mesh edges*, and their corners are *mesh vertices*. A mesh edge must not contain mesh vertices in its interior.

The boundaries defined in the geometry are discretized (approximately) into mesh edges, referred to as boundary elements (or *edge elements*), which must conform with the mesh elements of the adjacent domains.

The geometry vertices are represented by vertex elements.

3D GEOMETRIES

The mesh generator discretizes the domains into *tetrahedral*, *hexahedral*, *prism*, or *pyramid* mesh elements whose faces, edges, and corners are called *mesh faces*, *mesh edges*, and *mesh vertices*, respectively.

For 3D meshing, platforms handle floating-point operations differently, which sometimes results in slight differences between identical model files that are generated on two different computers.

The boundaries in the geometry are discretized into triangular or quadrilateral boundary elements. The geometry edges are discretized into edge elements.

Similar to 2D, the geometry vertices are represented by vertex elements.

PYRAMID ELEMENTS

Pyramid elements appear in the mesh in these situations. If you:

- Import a NASTRAN® file containing pyramid elements.
- Create a [Swept](#) mesh where the source and destination faces share an edge and the source face contains a triangular mesh.
- [Convert](#) a quad mesh to a triangular mesh for a face adjacent to a domain that contains a mesh.
- If you create a [Free Tetrahedral](#) mesh in a domain that is adjacent to a face with quadrilateral elements.

Create a [Boundary Layers](#) mesh in 3D for a geometry with sharp edges.

The *Hermite* and *divergence* types of finite elements do not work with pyramids.

Free (Unstructured) Meshing

The free mesher is available in all space dimensions, and you can use it for all types of geometries regardless of the topology or shape. If you have not defined or generated a mesh, the free mesher automatically creates an unstructured mesh and adds a corresponding node to the Model Builder when a study is computed.

When the free mesher is used:

- The number of mesh elements is determined by the shape of the geometry and various mesh parameters.
- The mesh parameters for the free mesher are controlled by [Size](#) and [Distribution](#) nodes in the meshing sequences.
- You can also control the size of the mesh elements generated by a specific [Free Triangular](#), [Free Quad](#), or [Free Tetrahedral](#) node by adding [Size](#) or [Distribution](#) subnodes (see Figure 8-1 for the settings in a Size subnode).

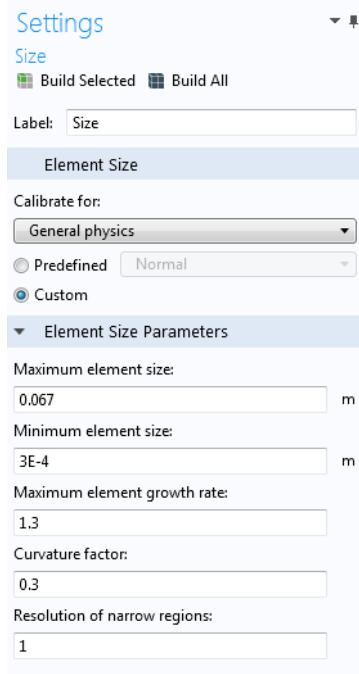

Figure 8-1: An example of custom element mesh sizes. You can also select Predefined element sizes.

You can define mesh parameters using numerical values, globally defined parameters, and built-in mathematical and physical constants.

2D MODEL UNSTRUCTURED MESHES

Free meshing generates an unstructured mesh with triangular or quadrilateral elements. Use the free mesher in 2D to create an unstructured mesh with triangular or quadrilateral elements. You can combine triangular and quadrilateral meshes by adding domains to the Domain list in the corresponding mesh operation's settings. From here, you can define specific meshing operations to each domain in your model.

3D UNSTRUCTURED MESHES

Free meshing generates an unstructured mesh with tetrahedral elements.

2D STRUCTURED MESHES

- You can create a structured triangular mesh by using the [Convert](#) operation to introduce a diagonal edge to quadrilateral elements.
- Also see [2D and 3D Boundary Layer Meshes](#) below.
- [Mapped](#) meshing generates a structured mesh with quadrilateral elements.

Compared to an unstructured mesh, the interior mesh vertices in a structured mesh are adjacent to the same number of elements. If you want to use mapped meshing on a geometry, you must build the geometry so that the domains are reasonably “regular” in shape and do not contain holes.

3D STRUCTURED MESHES

- [Swept](#) meshing generates a structured mesh (at least in the direction of the sweep) with prism or hexahedral elements. See [About Swept Meshes](#).
- [Boundary Layers](#) meshing generates structured layers of elements along specific boundaries integrating into an existing structured or unstructured mesh.

2D AND 3D BOUNDARY LAYER MESHES

The meshing type [Boundary Layers](#) is an example of a structured mesh. A boundary layer mesh is a mesh with dense element distribution in the normal direction along specific boundaries. This type of mesh is typically used for fluid flow problems in order to resolve the thin boundary layers along the no-slip boundaries.

- In 2D, a layered quadrilateral mesh is used along the specified no-slip boundaries.
- In 3D, the boundary layer mesh is a layered prism mesh or a hexahedral mesh, depending on whether the corresponding boundary-layer boundaries contain a triangular or quadrilateral mesh.

Boundary layer meshes can also resolve large temperature gradients close to heated surfaces subjected to sudden changes over time.

If you have the CFD Module or the Heat Transfer Module, [Heat Sink](#) shows the introduction of a boundary layer mesh at the surfaces of the inner half-circle arc.

About Swept Meshes

A [Swept](#) mesh is an example of a semistructured mesh since it is structured in the sweep direction and can be either structured or unstructured orthogonally to the sweep direction. The swept mesher operates on a 3D domain by meshing or reusing an existing mesh on a source face, and then sweeping the resulting face mesh along the domain to an opposite destination face. The swept mesh is typically a hexahedral mesh (hex mesh) or a prism mesh.

You can use several connected faces as source faces. Also the destination can consist of several faces, as long as each destination face corresponds to at least one source face and each source face corresponds to exactly one destination face. Each face about a domain that is to be operated on by the swept mesher is classified as either a source face, a destination face, or a linking face. The linking faces are the faces linking the source and destination faces (see [Figure 8-2](#)). The swept mesher can handle domains with multiple linking faces in the sweep direction.

The linking edges are the edges, or the chains of edges, connecting the source and destination faces. For a domain to be possible to sweep, there must be at least one linking edge or chain of edges.

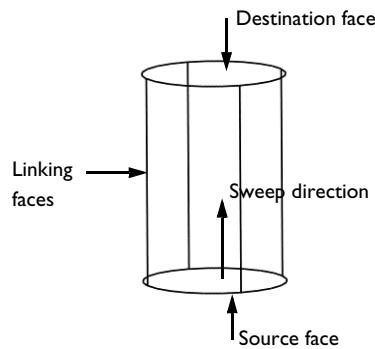

Figure 8-2: Classification of the boundaries about a domain used for swept meshing.

You can specify the source and destination faces manually, but in most cases the swept mesher can automatically identify source and destination faces from the geometry.

- If the source faces are not meshed prior to the sweeping operation, the Swept node automatically creates a quadrilateral (or triangular) mesh before sweeping it to the destination.
- If the source faces contain a triangular mesh, the resulting swept mesh consists of prism elements.
- If the source faces contain a quadrilateral mesh, the resulting swept mesh consists of hexahedral elements (hex elements).

The default is to create a quadrilateral face mesh but, depending on the source faces, that is not always possible.

For the sweeping technique to work, the geometry must satisfy these criteria:

- Each domain must be bounded by one shell; that is, a domain must not contain holes except if they penetrate both the source and destination face.
- The source and destination for a domain must be opposite each other in the domain's topology.
- Each destination face must correspond to one or more source faces.
- Each source face must correspond to precisely one destination face or a subset of it.
- The cross section along the direction of the sweep for a domain must be topologically constant.

Coincident source and destination faces are allowed.

If any of the faces about a domain is meshed prior to the sweeping operation, the following must be fulfilled.

- If the source and destination faces are meshed, these meshes must match.
- Structured quad meshes must be applied to the linking faces.

[Swept and Generating a 3D Swept Mesh](#)

Mesh Control Entities

Sometimes it is desirable to use certain geometric entities only to control the mesh. For example, you can add a curve inside a domain to control mesh element size there. If you mark this curve as a mesh control entity, it is not included in the geometry used when defining the physics interface and materials. An advantage is that the final mesh need not respect this curve exactly; it is used only to control element size.

Another situation where mesh control entities are useful is when you need precise control of the mesh in certain regions of the geometry. In these regions you typically use a structured mesh with distribution nodes to control the mesh. In other regions of the geometry you can use free (unstructured) mesh.

Suppose that you also want to insert boundary layers. If the boundaries separating the domains with structured and free mesh are ordinary geometry boundaries, the boundary layers have to respect them. This can lead to various problems, including low-quality elements or even meshing failures. If you instead mark such boundaries as mesh control entities, the boundary layer mesh algorithm has more freedom to move mesh nodes and to construct a better mesh.

The Mesh Toolbar

- [The COMSOL Desktop](#)
 - [Clear or Delete a Mesh](#)
 - [Errors and Warnings](#)
 - [Meshing Operations and Attributes](#)
-

After a **Mesh** has been added to the Component node, the **Mesh** ribbon toolbar (Windows) or the **Mesh** contextual toolbar (macOS and Linux) is made accessible. Click a meshing sequence node in the **Model Builder** and the **Mesh** tab or toolbar displays on the COMSOL Desktop.

In general, the instructions throughout the documentation indicate that you click a button on a **Mesh** toolbar, no matter what operating system you are running.

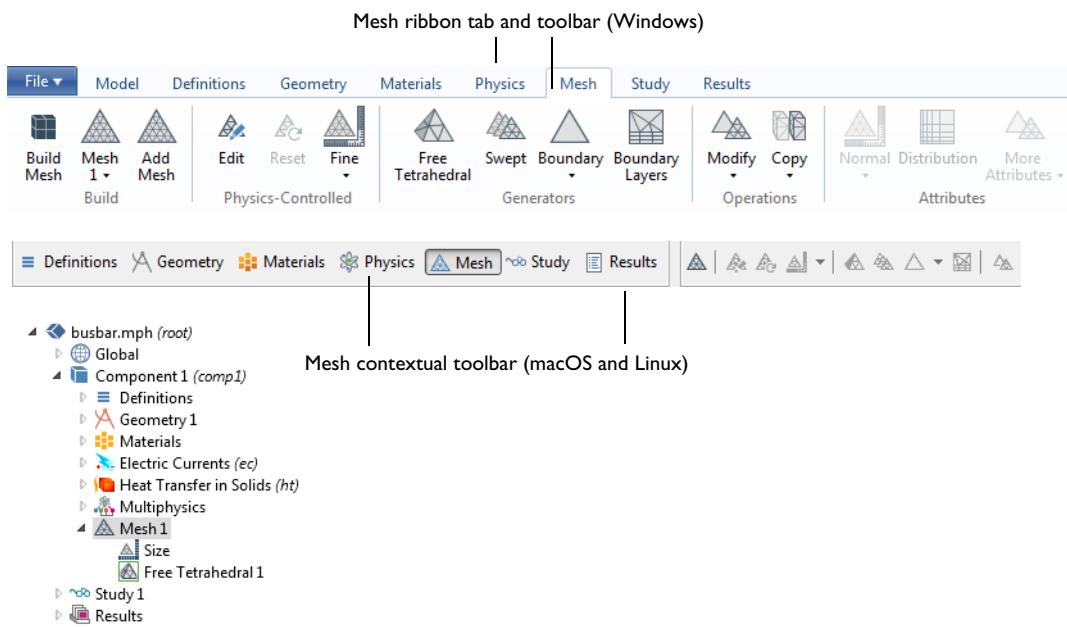

Figure 8-3: Click a Mesh node or any node under the Mesh node (Free Tetrahedral, for example) to open the Mesh ribbon toolbar (Windows users, top) or Mesh contextual toolbar (macOS and Linux users, bottom). Only some of the available buttons are shown in this image.

Click the associated menu arrow and choose the menu item corresponding to the mesh node. If you click the button associated with this menu button COMSOL Multiphysics selects the node in the **Model Builder** corresponding to the last selected item in the menu associated with the menu button.

PREDEFINED MESH ELEMENT SIZES

The following table shows the icons on the drop-down menus for selecting predefined mesh element sizes:

TABLE 8-1: PREDEFINED ELEMENT SIZE ICONS

ICON	NAME	ICON	NAME
	Extremely Fine		Normal
	Extra Fine		Coarse
	Finer		Coarser
	Fine		Extra Coarse
			Extremely Coarse

GEOMETRIC MEASUREMENTS

To measure the volume, area, or length of a selected domain, face, or edge, respectively, click the **Measure** button (). The result displays in [The Messages Window](#). Using this button it is also possible to view the

coordinates of a vertex, the distance between two vertices, or the number of entities and the geometry representation (only if you have license for the CAD Import Module) of a geometry object.

The **Mesh Toolbar** in 1D and 2D contains a subset of the tools in the 3D toolbar.

Adding, Editing, and Building Meshing Sequences

When you add a new Component to the Model Builder, a meshing sequence is added by default in the node **Mesh 1**. You can add more meshing sequences to the Component by right-clicking the **Component** node and selecting **Mesh**. When a Component has more than one meshing sequence, they are collected under a **Meshes** node. To add new meshing sequences to such a Component, you can alternatively right-click **Meshes**.

You create a mesh by building a meshing sequence, which contains a number of meshing operations as nodes in the sequence. For the default physics-controlled meshes, the software sets up the meshing sequences automatically.

For **Mesh** nodes created using adaptive mesh refinement, see [Meshes Generated by Adaptation](#).

ADDING MESH NODES

Right-click a **Mesh** node () in the Model Builder and then select an option from the context menu. Enter the properties in the **Settings** window. In numerical fields you can enter expressions that contain global parameters.

BUILDING SELECTED MESH NODES

To build all nodes (if needed) from the first up to the selected node:

- In a **Settings** window, click the **Build Selected** button ().
- Right-click a node under the main **Mesh** node and select **Build Selected**. Or click the node and press F7.
- Windows users: In the **Home** or **Mesh** ribbon toolbars, click **Build Mesh**.
- macOS and Linux users: In the **Model Toolbar** or the **Mesh Contextual Toolbar**, click **Build Mesh**.

BUILD ALL MESH NODES

To build all nodes in the meshing sequence (if needed):

- In a **Settings** window, click the **Build Mesh** button ().
- Right-click the main **Mesh** node () and select **Build All**. Or click the **Mesh** node and press F8.
- Windows users: In the **Home** or **Mesh** ribbon toolbars, click **Build Mesh**.
- macOS and Linux users: In the **Model Toolbar** or the **Mesh Contextual Toolbar**, click **Build Mesh**.

EDITING MESH NODES

To edit a mesh node, select it in the tree, and make changes in the **Settings** window that appears. Nodes that you have edited display with an asterisk (*) at the upper-right corner of the icon () in the **Model Builder**. The following nodes are marked with a yellow triangle at the lower-right corner of the node's icon to indicate that they need to be rebuilt. To see the result of your edits in the graphics, use the methods described above to either **Build Selected** or **Build All** nodes.

Using Meshing Sequences: Application Library path
COMSOL_Multiphysics/Meshing_Tutorials/meshing_sequence

Mesh (Node)

The main **Mesh** nodes () are the main nodes for meshing sequences. See [Adding, Editing, and Building Meshing Sequences](#) above for more information about meshing sequences.

The **Mesh** node's **Settings** window contains the following sections:

MESH SETTINGS

From the **Sequence type** list, choose **Physics-controlled mesh** (the default) to let the physics interfaces determine meshing sequence according to the **Physics-Controlled Mesh** section below, or choose **User-controlled mesh** to control the mesh directly using subnodes to this **Mesh** node, such as **Size** nodes. See [Choosing a Meshing Sequence Type](#) for more information.

PHYSICS-CONTROLLED MESH

This section is only available when the **Sequence type** list is set to **Physics-controlled mesh**.

From the **Element size** list, choose an element size for the mesh from **Extremely coarse** to **Extremely fine** (default value: **Normal**).

In the table below, all active physics interfaces and moving mesh features in the model component appear in the **Contributor** column. By default, all check boxes under **Use** are selected so that all listed physics interfaces and moving mesh features contribute to the mesh control suggestions. Clear some of the check boxes if desired to control which physics interfaces that contribute to the physics-controlled mesh.

Using Mesh Parts

You can use mesh parts for importing and preparing a mesh for use in a geometry sequence or meshing sequence. A mesh part is defined by an imported mesh from an STL, VRML, NASTRAN, MPHBIN, or MPHTXT file, or from some other meshing sequence. In addition, you can use mesh import operations to delete or partition parts of the mesh, for example, to prepare the imported mesh for use in a geometry sequence or meshing sequence, where you refer to the mesh part in an **Import** node. To insert the mesh into the new component, you can use a **Copy** node in the meshing sequence, where you use the mesh from the mesh part as the source.

When importing a NASTRAN file in the mesh part, it may include material definition, variables, and selections. All those properties are transferred to the component where you import the mesh part.

CREATING A MESH PART

You can add mesh parts from the **Global Definitions** node (🌐) by right-clicking it and, from the **Mesh Parts** submenu, select **3D Part**, **2D Part**, or **ID Part**. If a **Mesh Parts** node (📐) already exists under **Global Definitions**, you can add another mesh part by right-clicking it and then select **3D Part**, **2D Part**, or **ID Part**. You can also create a mesh part by adding an **Import** node (see [Import](#) in the [Geometry Modeling and CAD Tools](#) chapter) and choosing **Mesh or STL** (in 3D) or **Mesh** (in 1D and 2D) as the source.

Within the mesh part you add an **Import** node (see [Import](#)) to import a mesh. In 2D and 3D, you can then add additional nodes for partitioning the mesh, deleting and joining entities, and creating vertices. Such operations can be useful to define additional domains, for example. There is also a **View** node with view settings (see [User-Defined Views](#)) below the mesh feature nodes.

USING A MESH PART IN A GEOMETRY SEQUENCE

In a geometry sequence or part you can create an instance of the mesh part by right-clicking the **Geometry** node and adding an **Import** node. Then choose **Mesh or STL** (in 3D) or **Mesh** (in 1D and 2D) from the **Source** list and choose the mesh part from **Mesh** list below to use the mesh part in the geometry sequence.

From Surface Mesh to Geometry: STL Import of a Vertebra: Application Library path
COMSOL_Multiphysics/Meshing_Tutorials/stl_vertebra_import

Mesh Part Settings

Under a **Mesh Part** node you add nodes for importing and modifying an externally generated mesh.

The **Settings** window for a **Mesh Part** node contains the following section:

UNITS

Mesh files are unitless, which means that the physical size of an imported mesh is independent of the length unit of the mesh part. Select the **Use units** check box to use the length unit and angular unit (which you specify using the **Length unit** list and **Angular unit** list, respectively) in the nodes appearing under the Mesh Part node.

If the mesh part and the component referring to the mesh part have different unit systems, the resulting geometry is scaled.

Meshes Generated by Adaptation

The solvers can generate adapted meshes for several problem types. See [Adaptation and Error Estimates](#) and [The Adaptive Mesh Refinement Solver](#).

The meshes generated by the stationary or eigenvalue adaptive solver are based on the original meshing sequence and can be modified. The settings window for such a meshing sequence shows a reference to the generating study in the **Adaptation study** list. Click the **Go to Source** button () to move to that generating study. Click the **Disconnect from Study and Edit** button to unlock the sequence and enable editing. Note that unlocking the sequence disconnects the mesh from the study that generated it; if you run the study again, this mesh is ignored and a new meshing sequence is generated. However, you can manually select this meshing sequence in the mesh selection of a study step, to run the study on the adapted and modified mesh.

Adapted meshes generated by the time-dependent adaptive solver are generated directly by the solver and cannot be further edited. If you alter the geometry, these meshes are no longer compatible with the geometry and are therefore removed.

The Mesh Statistics Window

For statistical information about the mesh element quality, right-click the **Mesh** node () and select **Statistics** (). The **Statistics** window includes information about the minimum and average mesh element quality and a mesh element quality histogram, which shows the relative frequency of mesh elements with different quality values. The window contains the following sections:

GEOMETRIC ENTITY SELECTION

Define the geometric entities for which you want to display the statistics. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to view statistics for the entire mesh.
- Choose **Domain** to specify the domains for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the domains in the Graphics window or choose **All domains**.
- Choose **Boundary** to specify the boundaries for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the boundaries in the Graphics window or choose **All boundaries**.
- Choose **Edge** to specify the edges for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the edges in the Graphics window or choose **All edges**. This option is only available in 3D.
- Choose **Point** to specify the points for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the points in the Graphics window or choose **All points**. This option is only available in 2D and 3D.

ELEMENT QUALITY

From the **Quality measure** list, choose the mesh quality measure to use for the mesh statistics:

- **Skewness**, the default quality measure
- **Maximum angle**
- **Volume versus circumradius**
- **Volume versus length**
- **Condition number**
- **Growth rate**

For more information about these mesh quality measures, see [Mesh Element Quality and Size](#).

STATISTICS

In this section you find information on the status of the mesh: for example, if the mesh is empty, if the geometry is partially meshed, or if the geometry is completely meshed. You can select the element type for which you want to see statistics from the **Element type** list. The default is to display statistics for **All elements**. The statistics includes the number of mesh elements of different types, such as tetrahedral elements and triangular elements. In the element statistics section below — for example, **Domain element statistics** — you find information about:

- The number of elements.
- The minimum and average element quality, based on the selected mesh quality measure. The element quality is a scalar value between 0 and 1, where a higher number indicates a higher mesh element quality.
- The element volume ratio or area ratio, which is the ratio between the volumes (areas) of the largest and smallest element.
- The mesh volume or area (the total volume or area for the mesh), or the mesh edge length when applicable.

Not all these quantities are available for all options in the **Element type** list.

ELEMENT QUALITY HISTOGRAM

This section displays a histogram plot of the mesh element quality, using the selected mesh quality measure, for the specified element type and selection. The x -axis represents the element quality, and the y -axis represents the number of elements of similar quality. The absolute value of the mesh element quality is always between 0 and 1, where 0.0 represents a degenerated element and 1.0 represents the best possible element.

You can also create a histogram plot of the mesh element quality over the total area or volume of the elements by adding a [Histogram](#) plot to a 1D Plot Group and using a variable for a mesh quality measure as the expression.

Choosing a Meshing Sequence Type

PHYSICS-CONTROLLED MESH

If you select **Physics-controlled mesh** in the **Sequence type** list in the **Settings** window of a **Mesh** node and build the meshing sequence, COMSOL Multiphysics creates a mesh that is adapted to the current physics interface settings in the model. The default is to use physics-controlled mesh. For example, for a fluid-flow model you get a somewhat finer mesh than the default with a boundary layer mesh along the no-slip boundaries. If you want to modify the overall element size of the physics-induced mesh, select another element size from the **Element size** list in the **Settings** window of the main **Mesh** node and rebuild the mesh. If you change the physics interface settings in the model and rebuild the meshing sequence, COMSOL Multiphysics creates a new mesh adapted to the new physics interface settings.

A physics-induced mesh is not adapted by numerical error estimates — that type of adaptive meshing is provided by mesh adaptation in the solver sequence.

To edit a physics-induced meshing sequence, or to see the errors and warnings of a failing mesh build, select **User-controlled mesh** in the **Sequence type** list or right-click the **Mesh** node and select **Edit Physics-Induced Sequence** (). The program then adds the nodes under the main **Mesh** node that together form the physics-controlled mesh.

By doing this, the sequence is no longer updated according to changes that applied to the physics interface settings in the model.

If you right-click the **Mesh** node and select **Reset to the Physics-Induced Sequence** (), the sequence is reset to the physics-induced sequence. However, the type of the sequence is still **User-controlled mesh**. To switch back to physics-controlled meshing, select **Physics-controlled mesh** in the **Sequence type** list in the **Settings** window of the mesh node. If you add a node to the sequence, the type of the sequence automatically switches to **User-controlled mesh**.

USER-CONTROLLED MESH

Alternatively, you can use a user-controlled mesh. It is then possible to manually build and edit the meshing sequence using the meshing techniques described below for creating 2D and 3D meshes.

If you select **User-controlled mesh** from the **Sequence type** list in the main **Settings** window for a **Mesh** node, the program adds a **Size** node and a node for the default mesher (**Free Triangular** in 2D, for example). If the **Sequence type** list is set to **Physics-controlled mesh** and you add a **Size** node, for example, the meshing sequence switches to a user-controlled mesh, but no default mesher is added.

Mesh Element Quality and Size

The mesh resolution and mesh element quality are important aspects to consider when validating a model. Low mesh resolution — in relation to the variations in the solution and the geometry — can lead to inaccurate results. A low mesh element quality — which measures the regularity of the mesh elements' shapes — can lead to inverted mesh elements (see [Avoiding Inverted Mesh Elements](#)) and to high condition numbers for the Jacobians, which in turn can cause convergence issues. The mesh element quality is a dimensionless quantity between 0 and 1, where 1 represents a perfectly regular element, in the chosen quality measure, and 0 represents a degenerated element. COMSOL Multiphysics includes the following mesh quality measures:

- **Skewness**, which is the default quality measure, is a measure of the equiangular skew is defined as the minimum of the following quantity:

$$1 - \max\left(\frac{\theta - \theta_e}{180 - \theta_e}, \frac{\theta_e - \theta}{\theta_e}\right)$$

where θ is the angle over a vertex (2D) or edge (3D) in the element, θ_e is the angle of the corresponding edge or vertex in an ideal element, and the minimum is taken over all vertices (2D) or edges (3D) of the element.

- **Maximum angle**, which is based on the largest angle in the element. If no angle is larger than the largest angle of the corresponding optimal element, the quality is one; otherwise, the measure shows how much larger the angle is. This quality measure is insensitive to element anisotropy.
- **Volume versus circumradius**, which is based on a quotient of the element volume and the radius of the circumscribed sphere (or circle) of the element. This quality measure is sensitive to large angles, small angles, and anisotropy.
- **Volume versus length**, which is based on a quotient of element edge lengths and element volume. This quality measure is primarily sensitive to anisotropy.
- **Condition number**, which is based on the element dimension divided by the condition number (in the Frobenius norm) of the matrix transforming the element to a reference element.
- **Growth rate**, which is a measure of local (anisotropic) growth rate. Let $s_\alpha(E)$ denote the element size of an element E in a spatial direction α , and let E_α denote the element neighbor of E in the direction α . The growth rate measure is then the minimum of the quotient $\min(s_\alpha(E), s_\alpha(E_\alpha))/\max(s_\alpha(E), s_\alpha(E_\alpha))$, where α is taken over all directions.
- **Custom expression** (available in the **Mesh** plot node's Settings window), where you can enter a custom expression for the mesh quality (using the variables listed below, for example). The expression should evaluate to scalar values from 0 to 1.

The following built-in variables are available for these mesh quantities:

- h , the local mesh size.
- $qualskewness$, the skewness mesh quality measure, which is the default mesh quality measure.

- `qualmaxangle`, the maximum angle mesh quality measure.
- `qual1`, the volume versus circumradius quality measure.
- `qualvollength`, the volume versus length mesh quality measure.
- `qualcondition`, the condition number mesh quality measure.
- `qualgrowth`, the growth rate mesh quality measure.

All these variables are also available in variants for the various frames in a moving mesh or ALE simulation, for example. Append `_geometry`, `_mesh`, or `_spatial` to the base variable name to evaluate the quantity in the geometry frame, mesh frame, or spatial frame, respectively.

Using `qual` without a frame suffix refers to the material frame if several frames are used.

For quadrilateral and hexahedral elements with a large aspect ratio, which can appear in boundary layers, for example, the default mesh quality measure — skewness — and the maximum angle and growth rate quality measures report a high mesh quality, whereas the volume versus circumradius (the default and only quality measure) and the volume versus length quality measures report a low mesh quality because those measures take the aspect ratio into account.

In general, if a mesh with a low mesh quality has been generated, a **Warning** node appears, indicating where the bad elements are located in the geometry. To locate the exact placement of the bad elements, use a **Mesh** plot node set to show elements of the right dimension and using an element filter like `qualskewness<0.01`.

DISPLAYING MESH ELEMENT QUALITY AND THE MESH ELEMENT SIZE

You can display the mesh element quality and the mesh element size using, for example, a surface plot in 2D or a volume plot in 3D. You can always use a Mesh data set to display these quantities as soon as you have created a mesh. If you have a solution, you can also use a Solution data set. For a Component with a mesh, the following steps display the mesh element quality or mesh element size:

- 1 Right-click the **Mesh** node and select **Plot** (). This creates a plot group with a **Mesh** plot node ().
- 2 By default, this plot shows the mesh element quality. You can choose the mesh quality measure to display from the **Quality measure** list. In the **Settings** window for **Mesh**, select **Size** instead of **Quality** from the **Element color** list to plot the mesh element size instead.

Alternatively, you can access the built-in variables for mesh element quality (`qual1`) and mesh element size (`h`) in a surface plot, for example:

- 1 Under **Results** (), right-click **Data Sets** () and select **Mesh** ().
- 2 Add a 2D or 3D Plot Group using the Mesh data set as the group's data set, and then add a Surface or Volume plot. For example, in a **2D Plot Group>Surface** node (), from the predefined quantities (under **Mesh**), select **qualskewness - Element quality** (the default mesh quality measure), **h - Element size**, or one of the other available mesh element quality quantities for another quality measure. Then click the **Plot** button ().

- [Mesh \(Plot\)](#)
- [Mesh \(Export\)](#)
- [Mesh Report Node](#)

INVERTED MESH ELEMENTS

If you have a mesh that is coarse along a curved boundary, you might encounter problems with inverted mesh elements. This means that a mesh element is wrapped inside-out or has zero area (in 2D) or volume (in 3D). More precisely, there is some coordinate for which the Jacobian matrix for the mapping from local to global coordinates has a negative or zero determinant. In most cases, the linear (straight) mesh elements that you see in a mesh plot are not inverted, but the higher-order curved mesh elements used for computing the solution might be. Studying the minimum element quality therefore does not reveal the presence of inverted mesh elements in most cases.

Inverted mesh elements in themselves do not pose any immediate threat to the overall accuracy of your solution. However, if you are using an iterative solver, it might fail to converge. If you reach convergence and the solution looks good, it likely is. It is worth bearing in mind that the faces where there are inverted elements are less than perfectly resolved. If these faces are important for your results, you might want to pursue a mesh without inverted elements or at least make sure that the mesh resolution is sufficiently fine to guarantee an accurate solution. The easiest way to get an idea of the accuracy is to try a few different meshes and see how the solution changes. If the variation does not exceed your limits of acceptance, you are fine.

The solver prints a message about inverted curved elements to the **Messages** window and corresponding warnings to the **Log** window if they appear. **Warnings** nodes () also appear in the solver sequence where the inverted mesh elements appear. If you are using a **Free Tetrahedral** node to create the mesh, it is often possible to avoid inverted curved elements by selecting the **Avoid inverted curved elements** check box in the node's **Settings** window under **Element Quality Optimization**.

For a moving mesh, the mesh can become inverted, in which case an error occurs. In the **Error** node (, which appears in the solver sequence, information about the location of the inverted elements appears. The problematic mesh is available as a **Problematic Deformed Mesh** node () under **Meshes**, so that you can inspect the mesh around the coordinates for the inverted mesh elements.

USING LINEAR GEOMETRY SHAPE ORDER

When solving a model, the solver ensures that no inverted mesh elements are created. This is done by reducing the geometry shape order for the corresponding elements to first order. By default, the solver does this automatically. Alternatively, you can avoid problems with inverted mesh elements by using linear geometry shape order for all elements. You do this by choosing **Linear** from the **Geometry shape order** list in the **Model Settings** section of the **Settings** window for the main **Component** node.

VISUALIZING LINEARIZED ELEMENTS

The variable `linearizedelem` is 1 in elements that are linearized and 0 elsewhere. You can use this variable to identify mesh elements with linearized elements. For example, use `linearizedelem` as the expression in a plot.

MODIFYING THE GEOMETRY OR MESH

If you do not want to use linear geometry shape order to avoid problems with inverted mesh elements, you can try any of the following:

- Select the **Avoid inverted curved elements** check box in the **Free Tetrahedral** node's **Settings** window under **Element Quality Optimization**.
- Create a swept 3D mesh instead of using the free mesher.
- Avoid small curved boundaries such as fillets unless they are important for the result.

VISUALIZING INVERTED MESH ELEMENTS

You can visualize inverted mesh elements using the built-in `reljacmin` variable, which is the minimum of the determinant of the Jacobian matrix for the mapping from local (element) coordinates to global coordinates. A minimum value less than zero for an element means that the element is wrapped inside-out; that is, it is an inverted mesh element.

A typical visualization uses `reljacmin` as the quantity to plot as a volume plot. To display only the inverted elements, add a **Filter** subnode using the logical expression `reljacmin<0` to include only the inverted elements.

If you experience inverted mesh elements while meshing, you usually do not have a solution. In such cases, plot the logical expression `qual<0` instead, because `reljacmin` is not available. The plot then shows the inverted mesh elements as the elements for which the mesh quality is negative.

If you use `reljacmin`, the plot shows the quality of higher-order elements (if any), while `qual` always uses linear elements.

Troubleshooting Boundary Layer Mesh Generation

The boundary layer meshing algorithm is sensitive to the topology of the model geometry. If you get an error when trying to build a Boundary Layers node, try the following:

- Remove unnecessary interior boundaries such as boundaries (resulting from Boolean operations of geometry objects) that do not separate materials or physics. An efficient way to do this is to mark these boundaries as **Mesh Control Entities** in the Geometry Sequence. Once you have removed unnecessary boundaries, mesh the domains using a Free Tetrahedral or a Swept Mesh. When the domains are meshed, the control boundaries are automatically removed, and you can insert boundary layers, ignoring the interfering boundaries.
 - Use boundary layer mesh trimming instead of splitting. By default, the boundary layer mesher creates a boundary layer split at each sharp corner in 2D and along each sharp edge in 3D..
-

To turn off boundary layer splits, see [Boundary Layers](#).

If the mesh generator fails to generate a boundary layer mesh, **Error** nodes () appear under the **Boundary Layers** node. If the **Error** node contains details with coordinates for the location where it failed to create the mesh, the Graphics window indicates that location using red circles. Click the **Center at Coordinates** button to center the camera so that you can zoom into that location by clicking the **Zoom In** button () one or more times.

Troubleshooting Free Tetrahedral Mesh Generation

This section gives you some suggestions about how to solve problems that you might encounter when creating tetrahedral meshes.

BUILD A FINER MESH

As a general rule, it is easier to construct a mesh with smaller elements than a mesh with larger elements. If you get errors or low-quality elements when you try to mesh certain domains, try to decrease the element size using appropriate [Size](#) attributes on these domains.

USE AN APPROPRIATE MINIMAL ELEMENT SIZE

If your geometry contains details that are very small compared to the total volume of the mesh, you must ensure that the Minimum element size parameter in the corresponding [Size](#) attribute is at least as small as the smallest detail you wish to resolve. If this parameter is too large, you get warnings when building the node. For example, the warning “Edge is much shorter than the specified minimum element size” indicates that there are edges significantly shorter than the specified minimum element size. The resulting mesh gets badly shaped elements.

To locate small details, such as short edges and sliver faces, you can add and build a Free Tetrahedral node with normal size settings. Doing this results in warnings with selections that point you to the corresponding small entities. You can also inspect the mesh visually to locate unexpected small elements.

REMOVE UNWANTED GEOMETRY DETAILS

Sometimes, the geometry contains small features, like sliver faces and short edges, which you do not wish to resolve at all. Then you can use [Virtual Geometry Operations](#) in the sequence to ignore disturbing details of the geometry.

If you have a license for the CAD Import Module, you can also use CAD defeaturering operations to simplify the geometry.

PARTITION THE GEOMETRY INTO SIMPLE DOMAINS

If the geometry includes complex domains or complex faces that you have trouble meshing, you can try to partition the geometry into less complex entities. On a philosophical level, this method could be classified as a “divide and conquer” strategy. It is often possible to use the [Partition Objects](#) geometry feature to partition a complex domain into two domains. You can use a [Mesh Control Faces](#) node to make this partitioning only when building the mesh (see [Mesh Control Entities](#)).

To split a solid geometry object into parts using a [Work Plane](#), place the work plane where you want to cut the domain. Then add a **Partition** node from the **Boolean Operations** submenu, and select **Work plane** from the **Partition with** list in the **Settings** window for **Partition**.

Meshing Operations and Attributes

A meshing sequence corresponding to a geometry consists of [Mesh Operations](#) and [Mesh Attributes](#). The attribute nodes store properties that are used by the operation nodes when creating the mesh. You can also choose the [Predefined Mesh Element Sizes](#).

MESH OPERATIONS

The following table lists the available mesh operations:

TABLE 8-2: OPERATION NODES

ICON	NAME	DESCRIPTION	GEOMETRIC ENTITY LEVEL
	Adapt	Use adaptive mesh generation based on an error estimate from a computed solution.	Entire geometry and domain
	Boundary Layers	Create a boundary layer mesh — a mesh with dense element distribution in the normal direction along specific boundaries. This mesh is typically used for fluid flow problems to resolve the thin boundary layers along the no-slip boundaries.	Domain
	Convert	Some geometries have domains that are well suited for swept meshes. If there are surrounding domains that cannot be swept, you can use this to convert faces with quadrilateral mesh between these domains to faces with triangular mesh.	Domain and boundary
 2D 3D	Copy Domain	Copy a mesh between domains.	Domain
 2D 3D	Copy Edge	Copy a mesh between edges. A 3D Copy Edge feature can also be used for destination edges of different shapes.	Edge
	Copy Face	To make a copy of a mesh that you can use to create an identical mesh on, for example, two boundaries in a model with periodic boundary conditions.	Boundary
	Copy	Copy a mesh from another meshing sequence, typically of imported mesh type, or mesh part into a meshing sequence corresponding to a geometry.	Entire geometry, domain, boundary, or edge
	Edge	To create an edge mesh. This menu button works in the same way as the Free Tetrahedral button.	Edge
	Free Quad	Create an unstructured quadrilateral mesh. This menu button works in the same way as the Free Tetrahedral button.	Boundary
	Free Tetrahedral	Create an unstructured tetrahedral mesh. If no selection is specified, this feature creates a mesh on the remaining domains, boundaries, edges and points.	Domain, boundary, edge, or point
	Free Triangular	Create an unstructured triangular mesh. This menu button works in the same way as the Free Tetrahedral button.	Boundary
	Mapped	To create a structured quadrilateral mesh on boundaries in 3D and domains in 2D. This menu button works in the same way as the Free Tetrahedral button.	Boundary
	Reference	To refer to another meshing sequence. Building a Reference node runs the operation nodes of the referenced sequence.	

TABLE 8-2: OPERATION NODES

ICON	NAME	DESCRIPTION	GEOMETRIC ENTITY LEVEL
	Refine	Refine a mesh by splitting elements.	
	Swept	Create a swept mesh. In domain selection mode this button works in the same way as the Free Tetrahedral button. In boundary selection mode the software creates a swept mesh on the remaining domains using the selected boundaries as source faces.	Domain

MESH ATTRIBUTES

The following table lists the mesh attributes:

TABLE 8-3: MESH ATTRIBUTE NODES

ICON	NAME	DESCRIPTION
	Boundary Layer Properties	To specify the location of the boundary layers and the properties, such as the number and thickness of the boundary layers.
	Corner Refinement	To decrease the element size at sharp corners. The node considers a vertex in 2D or an edge in 3D to be a sharp corner if the angle between the adjacent selected boundaries, with respect to the selected domain, is greater than a specified angle.
	Distribution	To specify the distribution of mesh elements along an edge, for example. It is possible to add Distribution nodes both as global nodes and as local nodes.
	Edge Groups	To specify the four groups of edges around a boundary (3D) or domain (2D) that is used to determine the Mapped mesh of the boundary/domain.
	Edge Map	Using this node, the source mesh of the Copy Face or Copy Domain operation is transformed so that the source edge of the Edge Map node is mapped onto the destination edge of the Edge Map node with the specified orientation.
	One-Point Map	To define the orientation of the source mesh on the destination for a Copy Face or Copy Domain feature by specifying how to map one point adjacent to the source to a point adjacent to the destination.
	Scale	To scale the properties of the Size, Distribution, and Boundary Layer Properties nodes.
	Size	To specify the size of mesh elements. It is possible to add Size nodes both as global nodes and as local nodes.
	Size Expression	To specify the size of mesh elements using an expression evaluated on the grid or on a solution.
	Two-Point Map	To define the orientation of the source mesh on the destination for a Copy Face or Copy Domain feature by specifying how to map a pair of points adjacent to the source to a pair of points adjacent to the destination.

Adapt

An **Adapt** node () provides the possibility to use adaptive mesh refinement based on some error estimate from a computed solution. Adapt nodes are part of mesh sequences that the adaptive solver creates. You can also add **Adapt** nodes by right-clicking a **Mesh** node and select it from the **More Operations** submenu. An **Adapt** node modifies an existing mesh based on an expression, typically by refining the mesh based on error information from a solution.

	If you want to perform adaptive mesh refinement by manually adding an Adapt node, first create a new meshing sequence and copy the original mesh into that meshing sequence before adding an Adapt node.
--	--

The **Adapt** node's **Settings** window contains the following sections.

DOMAIN SELECTION

From the **Geometric entity** list, choose **Entire geometry** (the default) or **Domain** to select a set of domains for which the adaptation is active.

ADAPTATION

From the **Solution** list, select the solution to use for evaluation.

From the **Solution selection** list, select which solution that should be used to evaluate error estimates:

- Select **Use last** to use the last solution.
- Select **Use first** to use the first solution.
- Select **All** (the default for Eigenvalue studies) to use all solutions from that study.
- Select **Manual** to use a specific solution number that you specify as solution indices in the **Index** field.

In the **Weights** field (only available when **Solution selection** is **Manual** or **All**), enter weights as a space-separated list of positive (relative) weights so that the error estimate is a weighted sum of the error estimates for the various solutions (eigenmodes). The default value is 1, which means that all the weight is put on the first solution (eigenmode). That is, any omitted weight components are treated as zero weight.

From the **Type of expression** list, choose **Error indicator** (the default), **Absolute size**, or **Anisotropic metric**.

Error Indicator

If you select **Error indicator**, the following settings appear:

The **Error expression** list, where you can add expressions for the error, for example, in terms of the dependent variables (including the variables for error estimation). Use the **Move Up** (↑), **Move Down** (↓), **Add** (+) and **Delete** (⊖) buttons as needed. If you use several expressions, such as one for each solution component, the error expressions are added to form the sum of all of them. Or right-click a table cell and select **Move Up**, **Move Down**, **Add**, or **Delete**.

Use the **Adaptation method** list to control how to adaptively refine mesh elements. Select one of these methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. Use the **Allow coarsening** check box to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure.
- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements. This is the default method.

Use the **Element selection** list to specify how the element refinement vector is determined from the error expression. Select:

- **Rough global minimum** to minimize the L_2 norm of the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by a factor greater than 1 specified in the accompanying **Element count growth factor** field. The default value is 1.7, which means that the number of elements increases by roughly 70%. The **Error orders** field is an array of h -exponents for the decrease of the error expression. This array has the same indexing as the error expression's indexing. (for an error expression with two expressions such as `erreexpr1, erreexpr2` and error orders = 2, 3, it means that $\text{erreexpr1} = O(h^2)$ and $\text{erreexpr2} = O(h^3)$). When the adaptation method is used, these numbers are filled in automatically based on the **Residual**

order and **Error estimate** settings (on the adaptation study). The shape functions can also influence this order. Note that these order numbers need to be positive to generate additional elements (element growth).

- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements with the largest local error indicator.

Absolute Size

If you select **Absolute size**, the following settings appear:

In the **Size expression** field, type an expression for the element size (in terms of variables defined by the solution).

When you evaluate on a solution, the spatial variables (and any other length dependent variable, such as the local mesh size h), has the units of the component. So if your 2D geometry uses km as the length unit and is a unit square, assuming the component uses the SI unit system, the range of x and y would be 0 to 1000 (m) on the same geometry. Also note that the evaluated value of the expression is interpreted as a length in the geometry's unit system.

In 2D and 3D, use the **Adaption method** list to control how to refine mesh elements. Select one of the following methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. Use the **Allow coarsening** check box to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure.

It is not possible to coarsen hexahedral elements in the mesh.

- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements. This is the default method.

Anisotropic Metric.

This is an advanced option, where it can be difficult to formulate a useful and nontrivial anisotropic measure.

If you select **Anisotropic metric** (2D and 3D only), the following settings appear:

In the matrix (2-by-2 in 2D; 3-by-3 in 3D) that appears, you can enter a metric in upper-triangular parts (the matrix is a positive definite symmetric matrix). The expressions for the metric can vary in space and include the local mesh element size h . The default value is a diagonal matrix with the diagonal elements set to $1/h$, which means “no modification” for an isotropic mesh.

Boundary Layers

A **Boundary Layers** mesh () is a mesh with dense element distribution in the normal direction along specific boundaries. This type of mesh is typically used for fluid flow problems to resolve the thin boundary layers along the no-slip boundaries.

In 2D, a layered quadrilateral mesh is used along the specified no-slip boundaries.

In 3D, the boundary layer mesh is a layered prism mesh or a hexahedral mesh depending on whether the corresponding boundary-layer boundaries contain a triangular or a quadrilateral mesh.

Additional elements of an arbitrary type can also be inserted into the layers if needed.

To create a boundary layer mesh:

- In the **Graphics** window, select the boundaries where you want to insert boundary layer elements. On [The Mesh Toolbar](#) click the **Boundary Layers** button (). This adds a node with the same name, as well as a default **Boundary Layer Properties** node and at the same time inserts boundary layer elements for the selected boundaries, with the meshed domains adjacent to the selected boundaries as domain selection.
- In the **Mesh** ribbon toolbar (Windows) or from the **Mesh** contextual toolbar (macOS and Linux), click the **Boundary Layers** button ().
- Right-click a 2D or 3D **Mesh** node and select **Boundary Layers**.

Then enter the properties for the boundary layer mesher using the following sections:

DOMAIN SELECTION

Specify the domains where you want a boundary layer mesh by first choosing an option from the **Geometric entity level** list:

- Choose **Entire geometry** to specify boundary layer mesh for the entire geometry.
- Choose **Domain** to specify the domains for which you want a boundary layer mesh. Choose **Manual** in the **Selection** list to select the domains in the Graphics window or choose **All domains** to select all domains.

CORNER SETTINGS

The following options for handling boundary layers at sharp corners are available from the **Handling of sharp corners** list (in 2D) and the **Handling of sharp edges** list (3D):

- Select **Splitting** (the default) to introduce boundary layer splits at sharp corners. In the **Minimum angle for splitting** field you specify the minimum angle between adjacent boundary layer boundaries for a split to occur. Control the maximum angle of the elements in the split region by the **Maximum angle per split** parameter.
- Select **Trimming** to trim the boundary layer mesh at sharp corners. In the **Minimum angle for trimming** and in the **Maximum angle for trimming** fields you specify the minimum angle and maximum angle, respectively, between adjacent boundary layer boundaries for trimming to occur.
- Select **None** to not use any special treatment at sharp corners.

In the **Maximum layer decrement** field you can specify the maximum difference in number of boundary layers between neighboring points on boundary layer boundaries.

TRANSITION

Select the **Smooth transition to interior mesh** check box to smooth the transition in element size from the boundary layer mesh to the interior mesh. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

When a **Boundary Layers** node is added, a **Boundary Layer Properties** node is automatically added as a subnode. Use this subnode to specify the boundary layers and the properties of the boundary layers. If you want to specify different boundary layer properties for more than one boundary selection, right-click the **Boundary Layers** node and add additional **Boundary Layer Properties** subnodes. However, adjacent boundaries must have the same number of boundary layers.

- With the Batteries & Fuel Cells Module, see *Soluble Lead-Acid Redox Flow Battery (2D)*: Application Library path **Batteries_and_Fuel_Cells_Module/Flow_Batteries/pb_flow_battery**.
- With the CFD Module, see *Turbulent Flow Over a Backward Facing Step (2D)*: Application Library path **CFD_Module/Single-Phase_Benchmarks/turbulent_backstep**.
- With the Heat Transfer Module, see *Turbulent Flow Over a Backward Facing Step*: Application Library path **Heat_Transfer_Module/Verification_Examples/turbulent_backstep**.

Boundary Layer Properties

Add a **Boundary Layer Properties** node () to specify the location of the boundary layers and the properties, such as the number and thickness of the boundary layers.

By default, one Boundary Layer Properties node is added as a subnode to a **Boundary Layers** node. To add additional nodes, right-click a 2D or 3D **Mesh** node and select **Boundary Layers Properties**; then enter the properties using the following sections:

BOUNDARIES

Define the boundaries where you want boundary layers. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window or choose **All boundaries** to select all boundaries.

BOUNDARY LAYER PROPERTIES

The default **Number of boundary layers** is 8.

The default **Boundary layer stretching factor** is 1.2. This field is used to specify the increase in thickness between two consecutive boundary layers as a scaling factor; for example, entering 1.3 means that the thickness increases by 30% from one layer to the next.

To specify the thickness of the first element layer — the layer adjacent to the corresponding boundary — choose an option from the **Thickness of first layer** list: **Automatic** (the default) or **Manual**.

- If **Automatic** is kept as the default, the thickness of the first layer is $1/20$ of the local domain element height. Enter the **Thickness adjustment factor** to specify a scaling factor that multiplies this default size. The default is 1.
- If **Manual** is selected, the default **Thickness** (SI unit: m) is 0.00118 m.

The boundary layer meshing algorithm shrinks the boundary layers automatically if needed (for example, due to a narrow region); however, the stretching factor is always respected. In some cases the boundary layer meshing algorithm can choose to create fewer layers than specified. If this happens, a warning is printed to the Log page of [The Progress Window](#).

Convert

Use the **Convert** (□▣) node to convert quads to triangles in 2D and hexahedra, prisms, and pyramids to tetrahedra in 3D.

GEOMETRIC ENTITY SELECTION (3D) / DOMAIN SELECTION (2D)

First define the geometric entities where you want to convert the mesh elements. You choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to convert the mesh elements on all domains (and all boundaries in 3D).
- Choose **Domain** to specify the domains for which you want to convert mesh elements. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose **All domains** to select all domains, or choose any applicable user-defined selection, if available.
- Choose **Boundary** to specify the boundaries for which you want to convert mesh elements. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window, choose **All boundaries** to select all boundaries, or choose any applicable user-defined selection, if available. This option is only available in 3D.

ELEMENT SPLIT METHOD

From the **Element split method** list, select **Insert diagonal edges** (the default setting) to split each quadrilateral element into two triangular elements and each hexahedral element into five tetrahedral elements, or select **Insert center points** to split each quadrilateral element into four triangular elements and each hexahedral element into 28 tetrahedral elements. The conversion also affects quadrilateral elements on the boundaries of the specified domains in 3D.

Corner Refinement

Add a **Corner Refinement** node (▣) to decrease the element size at sharp corners. The node considers a vertex in 2D or an edge in 3D to be a sharp corner if the angle between the adjacent selected boundaries, with respect to the selected domain, is greater than a specified angle.

- In the **Mesh** ribbon toolbar (Windows), from the **Operations>Modify** (▲) menu choose **Size>Corner Refinement**.
- From the **Mesh** contextual toolbar (macOS and Linux), from the **Modify** (▲) menu choose **Size>Corner Refinement**.

- To add it as a global node, right-click a **Mesh** node and select **Corner Refinement**. To add it as a subnode to a **Mesh Operations** node, right-click an operation node and select **Corner Refinement**. See [Global vs. Local Attribute Nodes](#).

If there are several Corner Refinement nodes in the sequence with a nonempty selection intersection, the mesher uses properties corresponding to the last Corner Refinement node in the sequence.

Then enter the properties using the following sections:

DOMAIN SELECTION

Specify the domains for which the node determines if the specified corners are sharp. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify that the node should determine sharp corners with respect to all domains. The corner refinement also considers corners not adjacent to any domain.
- Choose **Domain** to specify the domains for which you want to determine sharp corners. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.

By default, Domain Selections are **Active** (the **Active** button is ON).

BOUNDARY SELECTION

To specify the boundaries, click the **Active** button to turn it ON and select the boundaries in the **Graphics** window for which the corner refinement should determine the sharp corners. When the boundary selection is **Active**, the **Domain Selection** section **Active** button is automatically turned OFF.

ANGLE

Use the **Minimum angle between boundaries** field to specify the minimum angle between a pair of adjacent boundaries in the boundary selection for the refinement factor to apply at the vertex in 2D and edge(s) in 3D between the two boundaries. If a boundary pair is adjacent to one domain on each side (interior boundary) the corner refinement determines the angle(s) on the side(s) corresponding to the specified domain(s).

REFINEMENT

Use the **Element size scaling factor** field to specify a refinement factor (<1) that scales the element size for the vertices in 2D and edges in 3D corresponding to the sharp corners.

Copy Domain

Add a **Copy Domain** node to 2D () or 3D () models to create identical meshes on domains.

Copying a mesh to a destination domain in 2D that is adjacent to a meshed domain is possible if the edges between these domains have the same number of elements as the corresponding source edges. The mesh on the destination edges is kept and the copied domain elements are modified to fit with this edge mesh.

Copying a mesh to a destination domain in 3D that is adjacent to a meshed domain is also possible if each face between these domains has a mesh isomorphic to a mesh of the corresponding source face. The mesh on the destination face is kept and the copied domain elements are modified to fit with this face mesh.

The edges around the source and destination domains in 2D are allowed to be partitioned differently but only in such a way that several edges of the source domain map to one edge of the destination edge. Not the other way around.

The faces around the source and destination domains in 3D are also allowed to be partitioned differently with exactly that same limitation (source to destination face mapping must be many-to-one).

If you copy between domains with a common boundary, the copy operation mirrors the mesh if the domains are symmetric. If the domains are symmetric but separated from each other, you can enforce a mirrored mesh by adding an **Edge Map** or a **Two-Point Map** subnode that controls the orientation of the copied mesh.

To copy a mesh between domains:

- In the **Graphics** window, select both the domains to copy the mesh from and the domains to copy the mesh to. Then on **The Mesh Toolbar** click the **Copy Domain** button in 2D (2D) or 3D (3D). This adds a node with the same name and copies the mesh and includes the source domains set to the selected domains with a mesh and the destination domains set to the selected domains without a mesh.
 - In the **Mesh** ribbon toolbar (Windows), from the **Operations>Copy** () menu choose **Copy Domain**.
 - In the **Mesh** contextual toolbar (macOS and Linux), from the **Copy** menu () choose **Copy Domain**.
- Right-click a **Mesh** node and choose **More Operations>Copy Domain**.

Then enter the properties for the copy meshing operation using the following sections:

SOURCE AND DESTINATION DOMAINS

It is possible to copy a mesh from one or several source domains onto one or several destination domains. The source (or their combination, if many-to-one is used) must be a connected set of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON and OFF selections. Select the domains to copy the mesh from in the **Graphics** window.

The source domains must be connected when the **Single destination (many-to-one)** option is specified. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Domain** nodes.

TYPE OF COPY

Select **Automatic** (the default) to let the software determine the proper copy method, select **Single destination (many-to-one)** to let the entire source mesh be copied onto each destination entity separately, and select **Array copy (many-to-many)** to let each single source entity mesh be copied onto a corresponding single destination entity.

Array copy (many-to-many) can be used only if a bijective transformation of source to destination can be found (a transformation that sets 1-to-1 mapping between source and destination).

SWITCH SELECTIONS

Click the **Switch Source and Destination** button to switch source and destination selections. Edge map is available to be switched, if provided.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the

Maximum element depth to process field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

To control the orientation of the source mesh on the destination when using the **Copy Domain** node, right-click and add an **Edge Map**, **One-Point Map**, or **Two-Point Map** node as a local attribute.

Copy Edge

Add a **Copy Edge** node to 2D (■■) and 3D (■■■) models to create identical meshes on edges. A 3D **Copy Edge** feature can also be used for destination edges of different shapes.

To copy a mesh between edges:

- In the **Graphics** window, select both the edges to copy the mesh from and the edges to copy the mesh to. On **The Mesh Toolbar**, click the **Copy Edge** button for 2D (■■) or 3D (■■■) models. This adds a node with the same name, copies the mesh, and includes the source edges set to the selected edges with a mesh and the destination edges set to the selected edges without a mesh.
 - In the **Mesh** ribbon toolbar (Windows), from the **Operations>Copy** (▲) menu choose **Copy Edge**.
 - In the **Mesh** contextual toolbar (macOS and Linux), from the **Copy** menu (▲) choose **Copy Edge**.
- Right-click a **Mesh** node and choose **More Operations>Copy Edge**.

Then enter the properties for the copy meshing operation using the following sections:

SOURCE AND DESTINATION EDGES

It is possible to copy a mesh from one or several source edges onto one or several destination edges. The source (or their combination, if many-to-one is used) must be a connected set of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON and OFF selections. Select the edges to copy the mesh from in the **Graphics** window.

The source edges must be connected when **Single destination (many-to-one)** option is specified. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Face** or **Copy Edge** nodes.

TYPE OF COPY

See [Copy Domain](#) for settings information.

SWITCH SELECTIONS

See [Copy Domain](#) for settings information.

CONTROL ENTITIES

See [Copy Domain](#) for settings information.

ORIENTATION

Select **Automatic orientation** to let the software determine the orientation of the source mesh on the destination automatically (this is the default), select **Same orientation** to let the source mesh be copied to the destination according to the direction of the edges, and select **Opposite orientation** to let the source mesh be copied to the destination in the opposite direction. Use the option **Show edge direction arrows** in the **View** node under the **Definitions** node to view the arrow direction.

Copy Face

For 3D models, use a **Copy Face** node () to make a copy of a mesh that you can use to create an identical mesh on, for example, two boundaries in a model with periodic boundary conditions.

Copying a mesh to a face that is adjacent to a meshed face is possible if the edges between these faces have the same number of elements as the corresponding source edges. The mesh on the destination edges is kept and the copied face elements are modified to fit with this edge mesh.

The edges around the source and destination faces are allowed to be partitioned differently, but only in such a way that several edges of the source face map to one edge of the destination edge, not the other way around.

Copying a face mesh in 3D is only possible if the destination face is not adjacent to any meshed domain. The copy node overwrites any existing mesh on the destination face.

To copy a mesh between faces:

- In the **Graphics** window, select both the boundaries to copy the mesh from and the boundaries to copy the mesh to. On **The Mesh Toolbar** click the **Copy Face** () button. This adds a node with the same name and copies the mesh and includes the source boundaries set to the selected boundaries with a mesh and the destination boundaries set to the selected boundaries without a mesh.
 - In the **Mesh** ribbon toolbar (Windows), from the **Operations>Copy** () menu choose **Copy Face**.
 - In the **Mesh** contextual toolbar (macOS and Linux), from the **Copy** menu () choose **Copy Face**.
- Right-click a **Mesh** node choose **More Operations>Copy Face**.

Then enter the properties for the copy meshing operation using the following sections:

SOURCE AND DESTINATION BOUNDARIES

It is possible to copy a mesh from one or several source boundaries onto one or several destination boundaries. The source (or their combination, if many-to-one is used) must be a connected set of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON  and OFF  selections. Select the boundaries to copy the mesh from in the **Graphics** window.

The source boundaries must be connected when the **Single destination (many-to-one)** option is specified as the **Type of Copy**. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Face** nodes.

TYPE OF COPY

See [Copy Domain](#) for settings information.

SWITCH SELECTIONS

See [Copy Domain](#) for settings information.

CONTROL ENTITIES

See [Copy Domain](#) for settings information.

The [Copy Edge](#) feature has an orientation section. To control the orientation of the source mesh on the destination when using the **Copy Face** node, right-click and add an [Edge Map](#), [One-Point Map](#), or [Two-Point Map](#) node as a local attribute.

Copy

For meshing sequences that are based upon a geometry, use a **Copy** node () to copy meshes within the same meshing sequence or between different meshing sequences (belonging to the same or different components). The dimension of the source meshing sequence must be less than or equal to the dimension of the destination meshing sequence. You can also copy a mesh from a mesh part.

The Copy feature can be useful if you start off with an imported mesh and then want to modify it by adding a boundary layer mesh or running a solver that modifies it, such as the adaptive solver. It also makes it possible to add geometry, such as for defining a surrounding domain, to an imported mesh while still keeping the imported mesh on the “original geometry”. Use the following steps to copy an imported mesh into another component’s geometry:

- 1 Import a mesh to an empty component or create a mesh part.
- 2 Add a new component in which you import the mesh as a geometry.
- 3 Add more geometry if desired.
- 4 In the new component’s meshing sequence, add a Copy feature that makes it possible to copy the imported mesh into this mesh.
- 5 Generate mesh on the additional geometry added in Step 3 or modify the mesh inserted in Step 4.

Enter the properties for the mesh copying operation using the following sections:

SOURCE MESH

From the **Mesh** list, select the meshing sequence or mesh part to copy from (or **None**, which is the default in 1D); then (for meshing sequences only) click **Copy** to copy the updated source mesh. By default, the meshing sequence in which the **Copy** node resides is selected. When this sequence is selected, the **Copy** button is unavailable. If you have parameterized the geometry or mesh and plan to run a parametric sweep, select the **Build source mesh automatically** check box to ensure that the source mesh and geometry are updated before copying. Otherwise, you have to manually rebuild the source mesh and click the **Copy** button if you want to use an updated source mesh. Click the **Go to Source** button () to move to the main **Mesh** node of the source mesh.

The sections below are available for 2D and 3D meshes only.

DIMENSION

Select the geometric entity level of the copy from the **Geometric entity level** list. The possible choices are **Entire geometry**, **Domain** (the default), **Boundary**, or **Edge** (3D only). For **Entire geometry**, the sections below are not available.

SOURCE ENTITIES

Use this section to select the entities to copy mesh from in the specified source mesh. From the **Selection** list, choose **All domains** (for example) or choose **Manual** to pick the entities from the **Graphics** window. Click the **Active** button to toggle between turning ON and OFF selections. Select the entities to copy the mesh from in the **Graphics** window. If you activate this selection, the **Graphics** window shows the mesh of the source sequence such that you can select entities in this mesh.

Click the **Swap Source and Destination** button () to swap the entities in the source list above and the entities in the destination list in the **Destination Entities** section below.

DESTINATION ENTITIES

This section is similar to the **Source Entities** section above, but you use it to define the geometric entities in the destination to which you want to copy the mesh.

TYPE OF COPY

See [Copy Domain](#) for settings information.

CONTROL ENTITIES

See [Copy Domain](#) for settings information.

Distribution

Use the **Distribution** node () to specify the distribution of mesh elements along an edge, for example. It is possible to add **Distribution** nodes both as global nodes and as local nodes. If there are several **Distribution** nodes in the sequence with a nonempty selection intersection, the mesher uses properties corresponding to the last **Distribution** node in the sequence. Distribution properties always override properties defined by **Size** nodes sharing the same selections.

- In the **Mesh** ribbon toolbar (Windows), from the **Operations>Modify** () menu choose **Size>Distribution**.
- In the **Mesh** contextual toolbar (macOS and Linux), from the **Modify** () menu choose **Size>Distribution**.
- To add it as a global node, right-click a **Mesh** node and select **Distribution**. To add it as a subnode to an operation node, right-click a **Mesh Operations** node and select **Distribution**. See [Global vs. Local Attribute Nodes](#).

GEOMETRIC SCOPE (3D) / BOUNDARIES (2D) / DOMAIN SELECTION (1D)

Define the geometric entities where you want to specify a distribution. Choose the level of the geometry from the **Geometric entity level** list (only available in 3D):

- Choose **Domain** to specify the domains for the distribution. Choose **Manual** from the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.
- Choose **Edge** to specify the edges for the distribution. Choose **Manual** from the **Selection** list to select the edges in the **Graphics** window or choose **All edges** to select all edges.

Edge is the only option in 2D, and **Domain** is the only option in 1D.

DISTRIBUTION

There are three main types of distribution methods that you select from the **Distribution types** list:

- Select **Explicit** to use an explicit, user-defined element distribution. To define the distribution of mesh elements, enter a vector-valued expression of strictly increasing values between 0 and 1, starting with zero (using comma-separated numbers) in the **Relative placement of vertices along edge** field, specifying the relative arc length values of the mesh vertices along the edge or boundary. Select the **Reverse direction** check box to reverse the direction of the explicit distribution.

- Select **Fixed number of elements** to use a fixed number of mesh elements, which you enter into the **Number of elements** field. This is the default option.
- Select **Predefined** to specify properties of a predefined distribution method that can be a geometric sequence (exponentially increasing or decreasing element size) or an arithmetic sequence (equal distance between elements); see below for details.

Settings for the Predefined Distribution Type

In the **Number of elements** field, enter the number of elements (the default is 5 elements). To specify the ratio in size between the last element and first element in the distribution, use the **Element ratio** field (the default value is 1.0; that is, the first and the last elements have the same size). From the **Growth formula** list, select **Arithmetic sequence** for a linear element distribution or select **Geometric sequence** for an exponential element distribution. Select the **Symmetric distribution** check box to get a symmetric distribution of elements, and select the **Reverse direction** check box to switch the element distribution to the opposite direction along the edge or boundary. If you have specified several edges in the selection, the **Reverse direction** check box refers to the edge in the selection with the lowest entity number (the *master edge* in the selection). For the other edges, their direction (with respect to the distribution) is such that the rotation with respect to the master edge is minimized.

Meshing Operations and Attributes

Edge

Add an **Edge** node () to mesh edges. You can control the number of elements and the distribution of elements in the edge mesh by using **Size** and **Distribution** nodes.

To create an edge mesh:

- In the **Mesh** ribbon toolbar (Windows), from the **Generators>Boundary** () menu choose **Edge**.
- From the **Mesh** contextual toolbar (macOS and Linux), choose **Edge** from the **Boundary** menu () (3D components) or click **Edge** (2D or 1D components).
- Right-click a **Mesh** node and choose **More Operations>Edge**.

Then enter the properties using the following sections:

EDGES (3D) / BOUNDARIES (2D) / DOMAINS (1D)

To define the edges where you want a create a mesh, first choose the level of the geometric entities from the **Geometric entity level** list:

- Choose **Entire geometry** to specify an edge mesh for the entire geometry.
- Choose **Remaining** to specify an edge mesh for remaining, unmeshed edges.
- Choose **Edge** (3D), **Boundary** (2D), or **Domain** (1D) to specify the edges for which you want to create a mesh. Choose **Manual** in the **Selection** list to select the edges in the **Graphics** window or choose **All edges** (3D), **All boundaries** (2D), or **All domains** (1D) to select all edges.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

Edge Groups

Use an **Edge Groups** node () to specify the four groups of edges around a boundary (3D) or domain (2D) that are used to determine the **Mapped** mesh of the boundary/domain.

For all the settings sections, click the **Active** button to toggle between turning ON  and OFF  selections.

To add this node, right-click **Mapped** and select **Edge Groups**. Then enter the properties using the following sections:

BOUNDARIES (3D) / DOMAIN SELECTION (2D)

Define the boundary/domain where you want to specify the edge groups. Choose **Manual** in the **Selection** list to select the boundary/domain in the **Graphics** window.

FIRST EDGE GROUP

Activate the **First Edge Group** list and select the edges for the first edge group in the **Graphics** window.

SECOND EDGE GROUP

Activate the **Second Edge Group** list and select the edges for the second edge group in the **Graphics** window.

THIRD EDGE GROUP

Activate the **Third Edge Group** list and select the edges for the third edge group in the **Graphics** window.

FOURTH EDGE GROUP

Activate the **Fourth Edge Group** list and select the edges for the fourth edge group in the **Graphics** window.

Edge Map

Use an **Edge Map** node () to specify the orientation of the source mesh on the destination for a **Copy Face** or a **Copy Domain** node. Using this node, the source mesh of the Copy Face or Copy Domain operation is transformed so that the source edge of the Edge Map node is mapped onto the destination edge of the Edge Map node with the specified orientation.

EDGES

Click the **Active** button to toggle between turning ON  and OFF  selections.

- Activate the **Source edge** list and select the edge that you want to define as the source edge in the **Graphics** window.
- Activate the **Destination edge** list and select the edge that you want to define as the destination edge in the **Graphics** window.

ORIENTATION

Select **Automatic orientation** to let the software determine the orientation of the mesh of the source edge on the destination edge (this is the default), select **Same orientation** to let the mesh of the source edge be copied to the destination edge according to the directions of the edges, or select **Opposite orientation** to let the mesh of the source edge be copied to the destination edge in the opposite direction.

Free Quad

Add a **Free Quad** node () to create an unstructured quadrilateral mesh on boundaries in 3D and domains in 2D. You can control the number, size, and distribution of elements by using **Size** and **Distribution** nodes.

To create an unstructured quadrilateral mesh:

- In the **Mesh** ribbon toolbar (Windows), from the **Generators>Boundary** () menu choose **Free Quad**.
- From the **Mesh** contextual toolbar (macOS and Linux), choose **Free Quad** from the **Boundary** menu () (3D components) or click **Free Quad** (2D components).
- Right-click a **Mesh** node and choose **Free Quad**. For 3D components, this is selected from the **More Operations>** menu.

The quadrilateral mesh generator does not strictly create only quadrilateral elements. In places of the geometry where it judges it as necessary, it can also create triangular elements.

Then enter the properties for the quadrilateral meshing operation using the following sections:

BOUNDARIES (3D) / DOMAINS (2D)

Define the boundaries (3D) or domains (2D) where you want to create an unstructured quad mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured quad mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create an unstructured quad mesh in the entire geometry.
- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create an unstructured quad mesh. Choose **Manual** in the **Selection** list to select the boundaries or domains in the **Graphics** window or choose **All boundaries** (3D) or **All domains** (2D) to select all boundaries or all domains.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x -scale, y -scale, and z -scale in 3D to positive real numbers. If any of the scale factors are not equal to one, the software scales the geometry in the x , y , and z directions before meshing; after meshing, it restores the geometry and mesh to fit the original size. The scale factors make it possible to generate meshes that are anisotropic. They are also useful if the mesh generator creates many elements due to a thin geometry or if the mesh generation fails due to large aspect ratios in the geometry.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

TESSELLATION

From the **Method** list, choose the tessellation method to use for creating an unstructured quadrilateral mesh:

- Select **Automatic** (the default) to make the mesh generator determine the best algorithm to use for each domain.
- Select **Legacy version 5.2** to use the algorithm available in version 5.2 and earlier versions of COMSOL Multiphysics.
- Select **Legacy version 5.2a** to use the algorithm available in version 5.2a of COMSOL Multiphysics, which, in addition to earlier versions of the free quad algorithm, has support for templates.

Free Tetrahedral

Add a **Free Tetrahedral** node () to create an unstructured tetrahedral mesh. If no selection is specified, this feature creates a mesh on the remaining domains, boundaries, edges and points. You can control the number, size, and distribution of elements by using **Size** and **Distribution** subnodes.

To create an unstructured tetrahedral mesh for a domain selection:

- In the **Graphics** window, select the domains. In the **Mesh** ribbon toolbar (Windows) or from the **Mesh** contextual toolbar (macOS and Linux), click the **Free Tetrahedral** () button.

Then choose the menu item corresponding to the desired predefined element size, for example, Normal. The software creates the resulting tetrahedral mesh by adding and building a Free Tetrahedral node, using the selected domains with a Size node, and using the selected predefined element size added as a subnode.

Alternatively, you can click the button associated with the menu button. Then COMSOL Multiphysics uses the last selected menu item (or Free Tetrahedral (Normal)), as indicated by the tooltip. If you use this menu button with an empty selection, the software meshes the remaining, unmeshed geometry.

- Right-click a **Mesh** node and choose **Free Tetrahedral**.

Then define the properties for the tetrahedral meshing operation using the following sections:

DOMAIN SELECTION

Define the domains where you want to create an unstructured tetrahedral mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured tetrahedral mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create an unstructured tetrahedral mesh in the entire geometry.
- Choose **Domain** to specify the domains for which you want to create an unstructured tetrahedral mesh. Choose **Manual** in the **Selection** list to select the domains in the Graphics window or choose **All domains** to select all domains.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x -scale, y -scale, and z -scale to positive real numbers. If any of the scale factors are not equal to one (1), the software scales the geometry in the x , y , and z directions before meshing. After meshing, it restores the geometry and mesh to fit the original size. The scale factors make it possible to generate meshes that are anisotropic, and they are useful if the mesh generator creates many elements due to a thin geometry or if the mesh generation fails due to large aspect ratios in the geometry.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

TESSELLATION

From the **Method** list, choose the Delaunay tessellation method to use for creating a tetrahedral mesh:

- Select **Automatic** (the default) to make the mesh generator determine the best algorithm to use for each domain.
- Select **Delaunay** to use a version of the Delaunay algorithm that under some conditions can modify the boundary mesh to simplify the meshing.
- Select **Delaunay (legacy version)** to use the Delaunay algorithm available in earlier versions of COMSOL Multiphysics. This is also the method that will be used if you open a model created using an earlier version of COMSOL Multiphysics.

ELEMENT QUALITY OPTIMIZATION

In this section, you can control how much effort COMSOL Multiphysics puts into optimizing the element quality and tuning the optimization for certain situations. From the **Optimization level** list, choose one of the following levels:

- **Basic** (the default), which makes basic optimizations aiming at a minimal element quality of 0.2.
- **Medium**, which makes more optimization and aims at a minimal element quality of 0.35,
- **High**, which attempts all available optimization operations. If the quality of the surface mesh is low (typically due to small details or narrow corners in the geometry), this setting can take a significant amount of time.

There are two additional settings that you can use if you then accept a lower mesh element quality:

- If the geometry includes fillets or other curved regions with a relatively coarse mesh, and you solve with a geometry shape order higher than one, you can select the **Avoid inverted curved elements** check box. This setting makes the optimization try to reduce the number of mesh elements that become inverted when they are curved. The cost of this optimization is longer meshing time and often a slightly higher number of mesh elements and a lower element quality.

If curved mesh elements become inverted, the following message appears in the **Messages** window:
Used linear geometry shape in N mesh elements to avoid inverted curved elements (where N is the number of inverted elements).

- If the computation is sensitive to too large mesh elements, you can select the **Avoid too large elements** check box. For each mesh element, there is a desired element size (h), specified by the mesh size parameters, and if the element is larger than that, COMSOL Multiphysics tries to make it smaller. The cost for this option is longer meshing time and a lower element quality. If you evaluate the maximum of h on a sufficiently large mesh of uniform size, this value is typically decreased by 10 percent if you have selected this option.
- Select the **Avoid too small elements** check box to optimize the mesh so that the diameter of the inscribed sphere of each element is maximized while still trying to respect the desired local element size. Optimizing this parameter can improve performance when solving problems using the discontinuous Galerkin method. The optimization level controls how much effort is put into this optimization.

For a tutorial about free meshing and mesh sizing, see *Free Tetrahedral Meshing of a Piston Geometry*, Application Library path: **COMSOL_Multiphysics/Meshing_Tutorials/piston_mesh**.

Free Triangular

Add a **Free Triangular** node () to create an unstructured triangular mesh on boundaries in 3D and domains in 2D. You can control the number, size, and distribution of elements by using **Size** and **Distribution** nodes.

To create an unstructured triangular mesh:

- In the **Mesh** ribbon toolbar (Windows), from the **Generators>Boundary** () menu choose **Free Triangular**.
- From the **Mesh** contextual toolbar (macOS and Linux), choose **Free Triangular** from the **Boundary** menu () (3D components) or click **Free Triangular** for 2D components.
- Right-click a **Mesh** node and choose **Free Triangular**. For 3D components, this is selected from the **More Operations>** menu.

Then enter the properties for the triangular meshing operation using the following sections:

BOUNDARIES (3D) / DOMAIN SELECTION (2D)

Define the boundaries (3D) or domains (2D) where you want to create an unstructured triangular mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured triangular mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create an unstructured triangular mesh in the entire geometry.
- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create an unstructured triangular mesh. Choose **Manual** in the **Selection** list to select the boundaries or domains in the **Graphics** window or choose **All boundaries** (3D) or **All domains** (2D) to select all boundaries or all domains.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x -scale, y -scale, and z -scale in 3D to positive real numbers. If any of the scale factors are not equal to one (1), the software scales the geometry in the x , y , and z directions before meshing. After meshing, it restores the geometry and mesh to fit the original size. The scale factors make it possible to generate meshes that are anisotropic, and they are useful if the mesh generator creates many elements due to a thin geometry or if the mesh generation fails due to large aspect ratios in the geometry.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

TESSELLATION

Here you can specify the triangulation method used when creating the triangular mesh. Select **Automatic** (default) to let the software use the method that is best suited for the geometry, select **Delaunay** to use a method based on a Delaunay algorithm, or select **Advancing front** to use a method based on an advancing front algorithm.

Mapped

Add a **Mapped** node () to create a structured quadrilateral mesh on boundaries in 3D and domains in 2D. You can control the number, size, and distribution of elements using **Size** (only the Maximum element size parameter is used) and **Distribution** subnodes.

To create a mapped quadrilateral mesh for each domain, the mapped mesher maps a regular grid defined on a logical unit square onto each domain. The mapping method is based on transfinite interpolation. The settings in the **Size** and **Distribution** nodes used by a **Mapped** node determine the density of the logical meshes. For the mapping technique to work, the opposite sides of each logical unit square must be discretized by the same number of edge elements.

By default, the relationship between the four sides of the logical unit square and the boundaries around a domain is based on a criterion related to the sharpest angle between boundaries. If you want to control this relationship, right-click the **Mapped** node to add an **Edge Groups** subnode.

2D Mapped Mesh Geometry

For the 2D mapped meshing technique to work properly, the geometry must be reasonably regular. The following conditions must be satisfied:

- Each domain must be bounded by at least four boundary segments.
- Each domain must be bounded by only one connected boundary component (that is, no holes are allowed).

- The domains must not contain isolated or embedded vertices or boundary segments.
- The shape of each domain must not differ significantly from a rectangle.

For a geometry model that does not initially meet these criteria, it is usually possible to modify it so that a mapped mesh is generated, for example, by splitting it into simpler domains.

To create a mapped quadrilateral mesh:

- In the **Mesh** ribbon toolbar (Windows), from the **Generators>Boundary** () menu choose **Mapped**.
- From the **Mesh** contextual toolbar (macOS and Linux), choose **Mapped** from the **Boundary** menu () (3D components) or click **Mapped** (2D components).
- Right-click a **Mesh** node and choose **Mapped**. For 3D models, this is selected from the **More Operations>** menu.

Then enter the properties for the mapped meshing operation using the following sections:

BOUNDARIES (3D) / DOMAIN SELECTION (2D)

Define the boundaries (3D) or domains (2D) where you want to create a mapped quad mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify mapped quad mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create a mapped quad mesh in the entire geometry.
- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create a mesh. Choose **Manual** from the **Selection** list to select the boundaries or domains in the **Graphics** window or choose **All boundaries** (3D) or **All domains** (2D) to select all boundaries or all domains.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

ADVANCED SETTINGS

In 3D, you can choose between two different interpolation methods in the **Interpolation method** list. This specifies how the mapped meshing operation determines the positions of the interior mesh points. If you select **Transfinite in 2D**, the positions of the interior mesh points are determined by transfinite interpolation in the 2D parameter space of the corresponding surface, and if you select **Transfinite in 3D**, transfinite interpolation is done in 3D to determine these positions. Select **Auto** to let the mapped meshing operation determine a suitable interpolation method automatically.

Select the **Adjust evenly distributed edge mesh** check box to allow the mapped mesher to automatically adjust the mesh on edges that are not already meshed and where no explicit distribution is applied.

For an example of a 2D mapped mesh, see *Tubular Reactor with Nonisothermal Cooling Jacket*: Application Library path **COMSOL_Multiphysics/Chemical_Engineering/tubular_reactor**.

One-Point Map

Use a **One-Point Map** node () to specify the orientation of the source mesh on the destination for a **Copy Face** or a **Copy Domain** node.

To add this subnode, right-click the **Copy Face** or **Copy Domain** node and select **One-Point Map** from the context menu. Then enter the properties using the following sections:

POINT SELECTION

Click the **Active** button to toggle between turning ON  and OFF  selections.

- Activate the **Point on source** list and select the point that you want to define as source point in the **Graphics** window.
- Activate the **Point on destination** list and select the point that you want to define as destination point in the **Graphics** window.

Reference

Use a **Reference** node () to refer to another meshing sequence. Building a **Reference** node runs the operation nodes of the referenced sequence. If you have a **Scale** node before a **Reference** node, or as a subnode to a **Reference** node, you can create a finer or coarser version of the mesh generated by the referenced sequence.

To refer to another meshing sequence:

- In the **Mesh** toolbar from the **Modify** menu, select **Reference** () .
- Right-click a **Mesh** node and select **Reference** in the **More Operations** submenu.

Then use the following section to specify the sequence to reference:

REFERENCE

Select the meshing sequence to reference.

It is possible to *expand* a reference (that is, replacing the reference with a copy of the referred sequence). If the reference node has a **Scale** subnode, the attribute nodes in the expanded sequence are scaled accordingly. In some cases, such scaling of attributes cannot be done explicitly, and additional scale nodes are created instead.

To expand a reference, right-click a reference node and select **Expand** () .

Refine

Use a **Refine** () node to refine a mesh by splitting elements.

To refine a mesh:

- In the **Mesh** ribbon toolbar (Windows), from the **Operations>Modify** () menu choose **Elements>Refine** () .
- In the **Mesh** contextual toolbar (macOS and Linux), from the **Modify>Elements** menu choose **Refine** () .
- Right-click a 2D or 3D **Mesh** node and from the **More Operations** submenu select **Refine**. In 1D, select **Refine** directly from the context menu.

Then use the following sections to specify the parts of the mesh to refine and the method used to refine the elements:

DOMAIN SELECTION

Define the domains where you want to refine the mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to refine the entire mesh.
- Choose **Domain, Boundary** (2D and 3D), or **Edge** (3D only) to specify the domains, boundaries, or edges for which you want to refine the mesh. Choose **Manual** from the **Selection** list to select the domains, boundaries, or edges in the **Graphics** window; choose **All domains**, **All boundaries**, or **All edges** to select all domains, all boundaries, or all edges, respectively; or choose any applicable user-defined selection available in the list.

REFINE OPTIONS

Refinement Method

From the **Refinement method** list, select **Regular refinement** or **Split longest side**. The regular refinement method bisects each edge of the element. The result is (with one exception) $2^{\text{element dimension}}$ new elements of the same type. For example, a triangle is split into four triangles; a prism element is split into eight prisms. The pyramid element is the exception: It is split into six pyramids and four tetrahedra. The longest side refinement method bisects the longest edge of each element. This method is generally not suitable for nonsimplex meshes because the refinement destroys the structured nature of such meshes; if you bisect one edge of a regular quad element, you get a triangle and a rather skewed quad element. For 1D elements, these methods are equivalent. For 1D models, this option is excluded.

Number of Refinements

Choose the number of consecutive mesh refinements from the **Number of refinements** list (the default is one refinement).

If you want to control the refinement by an element size expression rather than a fixed factor, you can use the **Adapt** node (see [Adapt](#)).

REFINE ELEMENTS IN BOX

Check **Specify bounding box** to refine the mesh only within a box. If you refine the mesh only on certain domains, the mesh is refined only in the intersection between the box and the domains.

Specify the box either by entering the coordinates of the lower-left corner and upper-right corner of the box or click **Draw box** to interactively specify the box (only available in 2D).

Scale

Use a **Scale** node (☒) to scale the properties of the **Size**, **Distribution**, and **Boundary Layer Properties** nodes. It is possible to add Scale nodes both as global nodes and as local nodes to [Reference](#) nodes. A Scale node that exists as a global node affects the size of the mesh elements generated by the subsequent operation nodes. A Scale node that exists as a subnode to a Reference node affects the size of the mesh elements generated by the Reference node only.

If two or more Scale nodes exist on the same selection, the resulting scale factor on that selection is the product of the given scale factors.

- To add this as a global node, in the **Mesh** toolbar from the **Modify** menu, select **Scale** (☒).
- To add this as a subnode, right-click a [Reference](#) node and select **Scale**. See also [Global vs. Local Attribute Nodes](#).

GEOMETRIC SCOPE

In this section you define the geometric entities where you want to specify a scale. Choose the level of the geometry from the **Geometric entity level** list.

- Choose **Entire geometry** to specify the scale for the entire geometry.
- Choose **Domain** to specify the domains for the scale specification. Choose **Manual** from the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.

- Choose **Boundary** to specify the boundaries for the scale specification. Choose **Manual** from the **Selection** list to select the boundaries in the **Graphics** window or choose **All boundaries** to select all boundaries.
- Choose **Edge** to specify the edges for the scale specification. Choose **Manual** from the **Selection** list to select the edges in the **Graphics** window or choose **All edges** to select all edges. This option is only available in 3D.
- Choose **Point** to specify the points for the scale specification. Choose **Manual** from the **Selection** list to select the points in the **Graphics** window or choose **All points** to select all points. This option is only available in 2D and 3D.

SCALE

Specify the scale factor in the **Element size scale** field.

A scale factor less than 1 gives smaller (more) elements; a scale greater than 1 gives larger (fewer) elements.

It is not possible to use a coarser mesh size setting on a geometric entity adjacent to a higher dimensional entity with a finer mesh size setting; the finer setting on a geometric entity overrides the coarser setting on its boundary. Therefore a scale factor larger than 1 might have no effect if the dimensional level of the selection is less than the space dimension.

Size

Use a **Size** node () to specify the size of mesh elements. It is possible to add Size nodes both as global nodes and as local nodes. If there are several Size nodes in the sequence with a nonempty selection intersection, the mesher uses properties corresponding to the last Size node in the sequence.

A meshing sequence corresponding to a nonempty geometry contains a Size node at the first position in the sequence. This Size node, referred to as the *default Size node*, is defined for the entire geometry and cannot be removed. To override the mesh size settings defined by this Size node, add another Size node to the sequence.

To add this node as a global node, right-click a **Mesh** node and select **Size**. To add this as a subnode, right-click a **Mesh Operations** node and select **Size**. Also see [Global vs. Local Attribute Nodes](#).

GEOMETRIC ENTITY SELECTION

This section is not available for the default Size node.

In this section you define the geometric entities where you want to specify a size. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify the size for the entire geometry.
- Choose **Domain** to specify the domains for the size specification. Choose **Manual** from the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.
- Choose **Boundary** to specify the boundaries for the size specification. Choose **Manual** from the **Selection** list to select the boundaries in the **Graphics** window or choose **All boundaries** to select all boundaries.
- Choose **Edge** (3D only) to specify the edges for the size specification. Choose **Manual** from the **Selection** list to select the edges in the **Graphics** window or choose **All edges** to select all edges. This option is only available in 3D.
- Choose **Point** to specify the points for the size specification. Choose **Manual** from the **Selection** list to select the points in the **Graphics** window or choose **All points** to select all points. This option is only available in 2D and 3D.

ELEMENT SIZE

In the **Calibrate for** list, select the physics node for which the element size is calibrated. The options available in some cases require module-dependent physics interfaces as indicated. In all cases, the default values for the **Element Size Parameters** are adjusted for the type of problem being solved.

- For any module, **General physics** and **Fluid dynamics** are options.
- If you have the Plasma Module and are using one of its plasma interfaces, choose **Plasma** from the **Calibrate for** list.
- If you have the Semiconductor Module and are using the Semiconductor interface, choose **Semiconductor** from the **Calibrate for** list.

The default element size is **Predefined** and set as **Normal**. See [Mesh Element Quality and Size](#) and [Predefined Mesh Element Sizes](#) for details about the options. This automatically determines the parameters that you can otherwise customize under **Element Size Parameters**.

Select **Custom** if you want to change the value for any parameters in the **Element Size Parameters** section.

ELEMENT SIZE PARAMETERS

This section is available when **Custom** is selected as the **Element Size**. Specify all element size parameters using numerical values or user-defined parameters.

Except for the default **Size** node, if you select a **Custom** element size above, the check boxes are automatically added next to each field. Click to select a check box to activate, and edit, the corresponding parameter.

The following parameters control the mesh element size (the parameters where you define a size use the geometry's length unit). Defaults vary based on whether it is a default node or not. Edit the default values as required for the following fields:

- **Maximum element size:** Use this parameter to limit the allowed element size, for example, if you want to limit the maximum element size to a fraction of the wavelength to make sure that the wave propagation is fully resolved. By using a parametric sweep to vary the maximum element size, you can solve the model using meshes with different mesh density to study how it affects the solution.
- **Minimum element size:** Use this parameter to specify the minimum allowed element size. You can use this value to, for example, prevent the generation of many elements around small curved parts of the geometry. If some details of the geometry are smaller than the minimum element size, the mesh will contain elements of a smaller size in order to resolve the geometry. This parameter is not available in 1D.
- **Maximum element growth rate:** Use this parameter to determine the maximum rate at which the element size can grow from a region with small elements to a region with larger elements. The value must be greater or equal to one. For example, with a maximum element growth rate of 1.5, the element size can grow by at most 50% (approximately) from one element to another.
- **Curvature factor.** Use this parameter to determine the size of boundary elements compared to the curvature of the geometric boundary (that is, the ratio between the boundary element size and the curvature radius). The curvature radius multiplied by the *curvature factor*, which must be a positive scalar, gives the maximum allowed element size along the boundary. A smaller curvature factor gives a finer mesh along curved boundaries. This parameter is not available in 1D.

Resolution of narrow regions: Use this parameter to control the number of layers of elements that are created in narrow regions (approximately). The value must be a nonnegative scalar. A higher value gives a finer mesh in narrow

regions. If the value of this parameter is less than one, the mesh generator might create elements that are anisotropic in size in narrow regions.

There is no guarantee that all mesh elements in the generated mesh strictly fulfill the size constraints given by the specified element size parameters.

It is not possible to use a coarser mesh size setting on a geometric entity adjacent to a higher dimensional entity with a finer mesh size setting; the finer setting on a geometric entity overrides the coarser setting on its boundary. A warning is given when coarser settings are overridden.

Meshing Operations and Attributes

Size Expression

Use a **Size Expression** node () to specify the size of mesh elements as an expression evaluated on a grid, a computed solution, or a temporary solution corresponding to the initial value of a study step. It is possible to add a **Size Expression** node both as a global node and as a local node. Free triangular, tetrahedral, and quadrilateral mesh operations that follow below the **Size Expression** node in the meshing sequence take the size expression into account.

For some types of adaptation and error estimation in the study settings (using mesh initialization), the adaptive solver add a **Size Expression** node to the meshing sequences that represent the adaptive mesh generation, but you can also add a **Size Expression** node to set up a mesh size expression of your choice. Right-click a **Mesh** node to add a **Size Expression** node from the context menu.

Only one **Size Expression** node per meshing sequence is supported.

To add this node as a global node, right-click a **Mesh** node and select **Size Expression**. To add this as a subnode, right-click a **Mesh Operations** node and select **Size Expression**. Also see [Global vs. Local Attribute Nodes](#).

GEOMETRIC ENTITY SELECTION

In this section you define the geometric entities where you want to specify a size expression. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify the size expression for the entire geometry.
- Choose **Domain** to specify the domains for the specification of the size expression. Choose **Manual** from the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.
- Choose **Boundary** to specify the boundaries for the specification of the size expression. Choose **Manual** from the **Selection** list to select the boundaries in the **Graphics** window or choose **All boundaries** to select all boundaries.
- Choose **Edge** (3D only) to specify the edges for the specification of the size expression. Choose **Manual** from the **Selection** list to select the edges in the **Graphics** window or choose **All edges** to select all edges. This option is only available in 3D.
- Choose **Point** to specify the points for the specification of the size expression. Choose **Manual** from the **Selection** list to select the points in the **Graphics** window or choose **All points** to select all points. This option is only available in 2D and 3D.

ELEMENT SIZE EXPRESSION

From the **Evaluate on** list, choose **Grid** (the default), **Solution**, or **Initial expression** to specify whether the evaluation is done on a grid, a solution, or an expression evaluated using initial values.

Evaluation on a Grid

Use the **Size expression** field to enter an expression for the absolute element size as a function of x , y , and z (depending on the space dimension). You can also use parameters and global functions, variables, and materials in the expression, but no features from the component are available. The actual size used in a coordinate is the minimum of the specified size expression and the result of the other size parameters (such as the maximum element size and the curvature factor), but this minimum is cut off by the specified minimum element size on a given entity, which acts as a lower bound. If the expression evaluates to something smaller than the minimum element size, you get a warning that the value was cut off.

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

To control the grid, you can specify the **Grid type**, which can be **Resolution**, where you specify the number of isotropic cells per dimension in the grid in the **Number of cells per dimension** field, or **Cell size**, where you specify the side length of a grid cell in the **Side length** field.

Evaluation on a Solution

From the **Solution** list, select the solution to use for evaluation.

From the **Solution selection** list, select which solution that should be used to evaluate error estimates:

- Select **Use last** to use the last solution.
- Select **Use first** to use the first solution.
- Select **All** (the default for Eigenvalue studies) to use all solutions from that study.
- Select **Manual** to use a specific solution number that you specify as solution indices in the **Index** field.

In the **Weights** field (only available when **Solution selection** is **Manual** or **All**), enter weights as a space-separated list of positive (relative) weights so that the error estimate is a weighted sum of the error estimates for the various solutions (eigenmodes). The default value is 1, which means that all the weight is put on the first solution (eigenmode). That is, any omitted weight components are treated as zero weight.

From the **Type of expression** list, choose **Error indicator** (the default) or **Absolute size**.

Error Indicator

If you select **Error indicator**, the following settings appear:

The **Error expression** list, where you can add expressions for the error, for example, in terms of the dependent variables (including the variables for error estimation). Use the **Move Up** (), **Move Down** () , **Add** () and **Delete** () buttons as needed. If you use several expressions, such as one for each solution component, the error expressions are added to form the sum of all of them. Or right-click a table cell and select **Move Up**, **Move Down**, **Add**, or **Delete**.

In 2D, use the **Refinement method** list to control how to refine mesh elements. Select:

- **Longest** to make the solver refine only the longest edge of an element.
- **Regular** to make the solver refine elements in a regular pattern.

Use the **Element selection** list to specify how the element refinement vector is determined from the error expression. Select:

- **Rough global minimum** to minimize the L_2 norm of the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by a factor greater than 1 specified in the accompanying **Element growth rate** field. The default value is 1.7, which means that the number of elements increases by roughly 70%. The **Error orders** field is an array of h -exponents for the decrease of the error expression. This array has the same indexing as the error expression's indexing. (for an error expression with two expressions such as `erreexpr1`, `erreexpr2` and error orders = 2, 3, it means that $\text{erreexpr1} = O(h^2)$ and $\text{erreexpr2} = O(h^3)$). When the adaptation method is used, these numbers are filled in automatically based on the **Residual order** and **Error estimate** settings (on the adaptation study). The shape functions can also influence this order. Note that these order numbers need to be positive to generate additional elements (element growth).
- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements with the largest local error indicator.

Absolute Size

If you select **Absolute size**, the following setting appears:

In the **Size expression** field, type an expression for the element size (in terms of variables defined by the solution).

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

Evaluation Using an Initial Expression

With this option, you can use a size expression that contains variable values in physics, material data, and settings made in the study (such as a frequency), with the same evaluation as you get when running **Get Initial Value for Step** on a study step. A typical application could be to adapt the mesh size to a (nonconstant) wavelength.

From the **Mesh** list, select a mesh (on the same geometry as the **Size Expression** node) on which the interpolation should be done. If **Automatic** (the default) is chosen, a mesh will be created automatically.

From the **Study step** list, choose a study step (for which **Get Initial Value for Step** will be run). If you choose **None** (the default), an empty study is created. The mesh that was specified above is used in the referenced or empty study step that you choose. These actions take place in a copy of the model and are therefore not visible in the **Model Builder** tree.

Use the **Size expression** field to enter an expression for the absolute element size as a function of x , y , and z (depending on the space dimension). You can also use variables and materials from the physics, parameters, and global functions and materials in the expression. The actual size used in a coordinate is the minimum of the specified size expression and the result of the other size parameters (such as the maximum element size and the curvature factor), but this minimum is cut off by the specified minimum element size on a given entity, which acts as a lower bound. If the expression evaluates to something smaller than the minimum element size, you get a warning that the value was cut off.

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

The following settings are available under **External changes**:

There is a caching scheme that caches various data required to compute the mesh size field. If you have changed something in the model, which has not been picked up by the code and thus invalidated the cache, you can clear the cache by clicking **Reevaluate with Updated Model**.

The selection in the **Update when parameter is changed** list provides the possibility to have the cache cleared whenever the values of the selected parameter are changed.

SMOOTHING

In this section, you can control the amount of smoothing of the mesh size expression. The **Maximum size field growth rate** (default: 1.4) controls how fast the size field can grow. It is a factor that must be larger than 1.0. Use a higher value to make the mesh coarser closer to areas with a small mesh size, which results in fewer mesh elements.

Meshing Operations and Attributes

Swept

The **Swept** node (▲) creates a swept mesh on a domain in 3D by sweeping the mesh from the source face along the domain to an opposite destination face. The source and destination can consist of several connected faces.

You can control the number, size, and distribution of elements using the **Size** and **Distribution** subnodes. The **Swept** node only reads properties from **Size** nodes defined on the entire geometry or on the domain level and **Distribution** nodes defined on the domain level.

In domain selection mode, this button works in the same way as the **Free Tetrahedral** button. In boundary selection mode, the software creates a swept mesh on the remaining domains using the selected boundaries as source faces.

To create a swept mesh:

- In the **Mesh** ribbon toolbar (Windows) or from the **Mesh** contextual toolbar (macOS and Linux), click the **Swept** (▲) button.
- Right-click a 3D **Mesh** node and select **Swept**.

- [About Swept Meshes](#)
- [Structured Meshes](#)

DOMAIN SELECTION

Specify the domains where you want a swept mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify swept mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to specify swept mesh for the entire geometry.
- Choose **Domain** to specify the domains for which you want a swept mesh. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window or choose **All domains** to select all domains.

SOURCE FACES

Click the **Active** button to toggle between turning ON and OFF selections.

To specify the source faces directly, activate the **Source Faces** list and select the faces defining the source of the sweep operation in the **Graphics** window.

Click the **Swap Source and Destination** button () to swap the faces in the source list above and the faces in the destination list in the **Destination Faces** section below.

DESTINATION FACES

To specify the destination faces directly, activate the **Destination Faces** list and select the faces defining the destination of the sweep operation in the **Graphics** window.

SWEEP METHOD

Face Meshing Method

In the **Face meshing method** list, you can specify how the unmeshed source faces, which are meshed automatically by the Swept node, are meshed:

- Select **Quadrilateral (generate hexahedra)** to generate a surface mesh with quadrilateral elements. This is the default meshing method.
- Select **Triangular (generate prisms)** to generate a surface mesh with triangular elements.
- Select **Quadrilateral (legacy version 5.2)** to generate a surface mesh with quadrilateral elements using the algorithm used in version 5.2 and earlier versions of COMSOL Multiphysics.
- Select **Quadrilateral (legacy version 5.2a)** to generate a surface mesh with quadrilateral elements using the algorithm used in version 5.2a of COMSOL Multiphysics.

Sweeping Path

Use the **Swept path calculation** list if you want to specify the shape of the sweep path:

- The default, **Automatic**, means that the sweeping algorithm automatically tries to determine if the sweep path is straight or circular; otherwise, a general approach is used.
- **Sweep following straight lines** means that all interior mesh points are located on straight lines between the corresponding source and destination points.
- **Sweep following circular arcs** means that all interior mesh points are located on circular arcs between the corresponding source and destination points.
- **Sweep using interpolation** means that the positions of the interior mesh points are determined by a general interpolation procedure.

Destination Mesh

Use the **Destination mesh generation** list if you want to specify the method to be used for transferring the source mesh to the destination:

- The default, **Determine suitable method**, means that the algorithm automatically tries to determine a suitable method for creating the destination mesh.
- **Use a rigid transformation** means that the destination mesh is created by a rigid transformation of the source mesh.
- **Morph source onto destination** means that the destination mesh is created from the source mesh by a morphing technique.
- **Project source mesh onto destination** means that the destination mesh is created from the source mesh by a projection technique.

CONTROL ENTITIES

Select the **Smooth across removed control entities** check box to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the boundary layer interface, for the mesh points to be smoothed.

LINKING FACES

You can choose between two different interpolation methods for the linking faces in the **Interpolation method for linking faces** list. This specifies how the mapped mesher, which is used by the swept mesher for the linking faces, determines the positions of the interior mesh points. For more information on the different option see [Mapped](#).

- *Laser Heating of a Silicon Wafer*: Application Library path
COMSOL_Multiphysics/Heat_Transfer/laser_heating_wafer
- *Deformation of a Feeder Clamp*: Application Library path
COMSOL_Multiphysics/Structural_Mechanics/feeder_clamp
- *Joule Heating of a Microactuator*: Application Library path
COMSOL_Multiphysics/Multiphysics/thermal_actuator_jh

Two-Point Map

Use a **Two-Point Map** node () to specify the orientation of the source mesh on the destination for a [Copy Face](#) or a [Copy Domain](#) node.

To add a Two-Point Map node as a subnode to a **Copy Face** or a **Copy Domain** node, right-click the node and select **Two-Point Map** from its context menu. Then enter the properties using the following sections:

SOURCE POINTS

Click the **Active** button to toggle between turning ON and OFF selections.

- Activate the **First point on source** list and select the point that you want to define as first source point in the **Graphics** window.
- Activate the **Second point on source** list and select the point that you want to define as second source point in the **Graphics** window.

DESTINATION POINTS

Activate the **First point on destination** list and select the point that you want to define as first destination point in the **Graphics** window.

Activate the **Second point on destination** list and select the point that you want to define as second destination point in the **Graphics** window.

Importing and Exporting Meshes

About Mesh Export, Import, and Operations on Imported Meshes

It can be useful to import meshes already created by external software or, alternatively, to export a mesh generated by COMSOL Multiphysics into other software. Importing an externally generated mesh can be helpful when a mesh is already saved in a file and recreating the geometry would be difficult and time consuming.

The partitioning of the mesh into domains, boundaries, edges, and points (vertices) is essential to set up the physics of each Component node. The available operations for imported meshes deliver some basic, but flexible, functionality. It is also possible to export a mesh for use in another software or for external manipulation of the mesh data.

Exporting Meshes

You can export a mesh to a COMSOL Multiphysics file (`.mphbin` for a binary file format or `.mphtxt` for a text file format) or to a NASTRAN file (`.nas`, `.bdf`, `.nastran`, or `.dat`).

A 3D mesh can also be exported to an STL file.

To open the **Export** window for exporting meshes, from the **Mesh** toolbar, click **Export** (↗), or right-click the **Mesh** node and select **Export** (↗) from the menu.

EXPORT

Select a file type among the available formats in the **File type** list and enter a filename including the path in the **Filename** field (or click **Browse** to specify the filename).

Click **Export** to export a mesh to the specified file. A confirmation message appears in the **Messages** window.

EXPORTING TO A COMSOL MULTIPHYSICS FILE

If you export a mesh to a COMSOL Multiphysics binary (`.mphbin`) or text (`.mphtxt`) file, you specify the type of elements to export using the **Domain elements**, **Boundary elements**, **Edge elements** (available in 3D), and **Vertex elements** (available in 2D and 3D) check boxes under **Data to export**. By selecting the **Geometric entity information** check box, the export operation also writes information on the corresponding geometric entity index for each element to the file. Select the **Selections** check box to also include mesh selections that are defined on the current geometry in the mesh export. Such selections can then be included when importing a mesh.

EXPORTING TO A NASTRAN FILE

If you export a 2D or 3D mesh to a NASTRAN file, you specify the type of elements to export using the **Domain elements** and **Boundary elements** (available in 3D) check boxes. By selecting the **Geometric entity information** check box, the export operation also writes information on each element's corresponding geometric entity index to the corresponding property identification field of the resulting NASTRAN file.

Under **Output settings**, use the **Field format** list to specify if the output NASTRAN file should be stored in the small field format (single precision), large field format (double precision), or free field format (comma separated). Select the **Export as linear elements** check box to export the linear element information only. By default, second-order elements are exported if second-order elements are available. Second-order elements are available for meshes generated in COMSOL Multiphysics and for imported meshes already containing second-order elements.

EXPORTING A 3D MESH TO AN STL FILE

You can export the boundary elements of a 3D mesh to an STL file in the binary or text format. Because the STL format only supports triangles, the export operation writes two triangles (defining a quad split) to the STL file for each quad element in the mesh.

There is also a mesh export option available under **Results>Export** (see [Mesh \(Export\)](#)). Use that mesh export if you have computed a solution and want to export the mesh from a deformed configuration or a (geometric) parameter configuration, for example. From the **Mesh** node under **Results>Export** you can also export the second-order element nodes used by the COMSOL Multiphysics solvers, which are not available in the mesh itself. Exporting the mesh on the NASTRAN file format is only available from the **Mesh** node's **Export** option.

Importing Meshes

You can import a mesh from a COMSOL Multiphysics native file or from another meshing sequence. In 3D you can also import meshes from NASTRAN, STL, or VRML files. In 2D you can also import 2D meshes from NASTRAN (the third coordinate must then be the same for all mesh points).

Importing a mesh clears the geometry defined in the corresponding geometry sequence. In order to use an imported mesh together with an existing geometry, import it in a separate component. Then use the [Copy](#) or [geometry Import](#) features to transfer the mesh to the geometry sequence.

When a mesh is imported into COMSOL Multiphysics, the Import node automatically determines a partitioning of the mesh into domains, boundaries, edges, and points. If the automatically performed partitioning does not match the requirements, you can modify the face partitioning by manually adjusting the corresponding parameters. To hide the geometry based on an imported mesh in a view, use an [Hide for Mesh Import](#) node.

To import additional meshes, add another Import node. Then COMSOL Multiphysics adds the elements and points of the newly imported mesh to the existing mesh.

Meshes from different Import nodes form an assembly.

Using Several Meshing Sequences of Imported Mesh Type

You can define several meshing sequences for the same geometry (see [Adding, Editing, and Building Meshing Sequences](#)). If the geometry sequence is empty (a necessary condition for the **Imported mesh** sequence type), the first **Mesh** node under the **Meshes** node defines a topology and is referred to as the *master sequence*. All of the other **Mesh** nodes should define a geometry topologically similar to the one defined by the master sequence. Two geometries are considered to be similar if they have the same number of geometric entities and their points have the same coordinates.

When you build a non-master sequence, COMSOL Multiphysics first builds the master sequence. If the build of the master sequence fails or if the geometries defined by these two sequences are not similar, an error occurs.

If you want to use the geometric multigrid solver, several meshing sequences must be added first.

[Import and Multigrid](#)

REMESHING IMPORTED MESHES

It is possible to remesh an imported mesh to create a new mesh more suited to solving the problem at hand. See [Creating Geometry from Mesh](#) for more information.

MODIFYING IMPORTED MESHES

For 3D and 2D imported mesh sequences, the Refine, Adapt, and Convert operations are available for modifying imported meshes. For 1D imported mesh sequences, the Refine and Adapt operations are available. See [Refine](#), [Adapt](#), and [Convert](#) for more information.

IMPORTING EXTERNALLY GENERATED MESH DATA

It is possible to import externally generated mesh data using a COMSOL mesh file. The file format contains a section with mesh points coordinates, followed by sections with mesh element information, divided into separate subsections for each mesh element type (see [Mesh](#) in the chapter *The COMSOL File Formats* in the *COMSOL Multiphysics Programming Reference Manual*).

Importing Incomplete Mesh Data

A COMSOL Multiphysics mesh contains elements for all space dimension levels. For example, a tetrahedral mesh consists of domain (tetrahedra), boundary (triangles), edge, and vertex elements. Furthermore, each element has an index to the geometric entity it belongs to. If a mesh file is incomplete — for example, if it only contains tetrahedra — the Import operation automatically generates the missing element data. To illustrate this behavior, import the file `mesh_example_1.mphtxt` from

```
applications/COMSOL_Multiphysics/Meshing_Tutorials/
```

This file contains domain elements only with geometric entity information dividing the mesh into two domains. Now, export the imported mesh to a file using the default settings. Then, compare the resulting file (see `mesh_example_4.mphtxt`) with the file `mesh_example_1.mphtxt` and note that the exported file contains complete mesh information; that is, it contains domain elements, boundary elements, edge elements, vertex elements, and geometric entity information.

Transferring Domain Information

If you have an externally generated mesh with a predefined partitioning of the elements, you can transfer this partitioning to COMSOL Multiphysics by specifying geometric entity information in the `.mphtxt` file. To illustrate this, import the file `mesh_example_2.mphtxt`. This file contains domain elements only, without any geometric entity information. The imported mesh consists of one domain only. Note that the imported mesh from the file `mesh_example_1.mphtxt` consists of two domains according to the given geometric entity information.

Transferring Boundary Information

To transfer boundary partitioning information of an externally generated mesh you need to include boundary elements with the corresponding geometric entity information in the `.mphtxt` file. To illustrate this, import the file `mesh_example_3.mphtxt` with the **Boundary partitioning** option set to **Minimal**. This file contains domain and boundary elements with geometric entity information defining 5 boundaries. Note that the imported mesh also has 5 boundaries. Now import the file `mesh_example_1.mphtxt`, which has no boundary information, using the same import settings. Note that the imported mesh now has 3 boundaries only because the Minimal option generates the minimal possible partitioning that is required by the topological criteria.

Creating Geometry from Mesh

A mesh imported into COMSOL Multiphysics can be used to construct a geometry. A situation in which this is useful is when you need to add more geometry (for example, a bounding box to mesh the surrounding of the imported mesh object), or if you want to modify the imported mesh (for example, by adding boundary layers).

- I Select the mesh part or meshing sequence with the imported mesh.

2 In the **Mesh** toolbar, click **Create Geometry from Mesh** () or right-click and select it from the context menu.

The COMSOL Multiphysics software creates a new model Component of the same dimension as the current mesh. The geometry sequence in the new component has an **Import** node that imports the original mesh as geometry.

REUSING THE ORIGINAL MESH

It is possible to use the original, imported mesh, or parts of it, in the new Component.

- 1 Add a **Copy** feature to the meshing sequence.
- 2 Select the original import sequence as Source Mesh.
- 3 Select source and destination entities.
- 4 Click the **Copy** button to copy the mesh. If you have added more geometry, you can use the usual mesh operations to add mesh to these entities. You can also add boundary layers to the copied mesh.

Operations on Imported Meshes

The following mesh import operation nodes make it possible to define the partitioning of an imported mesh into domains, boundaries, edges, and points, with respect to the physics interface settings of the Component.

TABLE 8-4: OPERATIONS ON AN IMPORTED MESH

ICON	NAME AND LINK	USE AND DESCRIPTION
	Ball	To split geometric entities in an imported mesh by an element set defined by a ball.
	Box	To split geometric entities in an imported mesh by an element set defined by a box.
	Create Vertex	To create an additional vertex in an imported mesh.
	Cylinder	To split geometric entities in an imported mesh by an element set defined by a cylinder.
	Delete Entities	To delete geometric entities from an imported mesh.
	Detect Faces	To split the geometric boundary entities in an imported mesh by detecting shapes that constitute faces.
	Join Entities	To join adjacent geometric entities in an imported mesh.
	Logical Expression	To split geometric entities in an imported mesh by specifying a logical expression.

Using Operations on an Imported Mesh

The following example shows how you can use the mesh import operations to control the partitioning of an imported mesh.

IMPORTED MESH

The following overview is based on using an imported mesh from the **feeder_clamp** model, found in the COMSOL Multiphysics Applications Libraries and shown in [Figure 8-4](#).

	<i>Deformation of a Feeder Clamp:</i> Application Library path COMSOL_Multiphysics/Structural_Mechanics/feeder_clamp
---	--

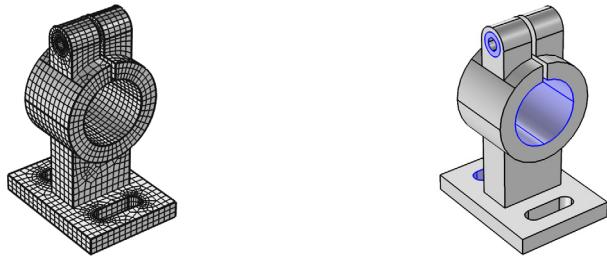

Figure 8-4: The Deformation of a Feeder clamp model showing an imported mesh, which is divided into 5 domains, 69 faces, 174 edges, and 114 points.

JOIN ENTITIES

To form a single domain, use a **Join Entities** (█) node, which operates on the domain level (that is, add **All domains** to the selection). As a result, you can obtain a mesh for the model with a single domain.

DELETE ENTITIES

To remove all edges, use a **Delete Entities** (█) node, which operates on the edge level (that is, add **All edges** to the selection). As a result, you can obtain a mesh for the model with no edges or points.

CYLINDER

To define a boundary that defines the contact between the feeder and the clamp, use a **Cylinder** (█) node that operates on the boundary level (that is, add **All boundaries** to the selection, and use 10.001 as a cylinder radius, 0 and -20 for top and bottom, (15, 0, 35) as position, and **y-axis** as the axis type).

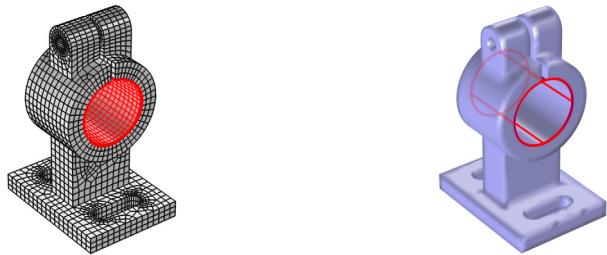

Figure 8-5: Using a Cylinder node to define the contact between the feeder and the clamp.

LOGICAL EXPRESSIONS

To define two boundaries that define screw channels, use a **Logical Expression** (█) node, which operates on the boundary level (that is, add **All boundaries** to the selection and use $(y+10)^2 + (z-55)^2 \leq 4$ as the expression).

Figure 8-6: Using a Logical Expression to create boundaries on the two screw channels of the feeder clamp.

BALL

To create a boundary defining one of the washers used for the boundary loads of the model, use a **Ball** (🌐) node, which operates on the boundary level (use (5, -10, 55) as a ball center and 3.5 as a ball radius). The input boundary selection must be limited; otherwise, the ball operation also splits one of the cylinder boundaries, which was created by the **Logical Expression** node.

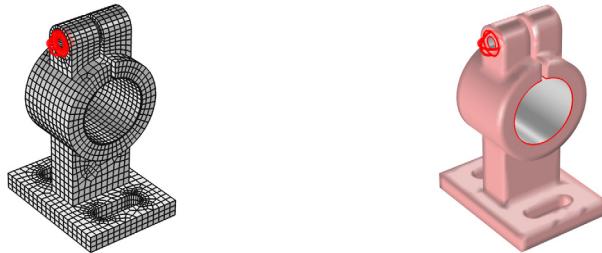

Figure 8-7: Using a Ball node to define one of the washers of the feeder clamp.

By creating a duplicate of the **Ball** node and modifying the ball center (set x to 5) you can create a boundary for the second washer.

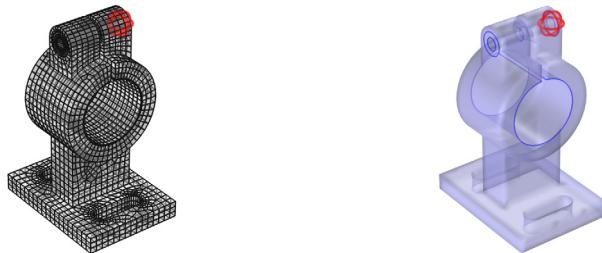

Figure 8-8: Using a Ball node to define a second washer.

BOX

To create the boundaries for the mounting holes, use a **Box** (📦) node, which operates on the boundary level (use (0 - 30, -30 - 10, 0.1 - 4.9) as box limits and use the **Some vertex** condition).

Figure 8-9: Using a Box node to define the mounting holes on the feeder clamp.

CREATE VERTEX

Using the **Create Vertex** () node, it is possible to add an additional vertex in a specified location (use (30, -30, 0) as vertex coordinates as in [Figure 8-10](#)).

Figure 8-10: Using a Create Vertex node to add vertices at specific locations on the feeder clamp.

Ball

Use a **Ball** node () to split geometric entities of an imported mesh by creating at least one new geometric entity for the elements enclosed in the specified ball.

To add a Ball node, right-click a 2D or 3D mesh node and select **Ball** from the **Partitions** menu. Then use the following sections to specify the geometric entities to split, the properties of the ball, and the split condition:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to split. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to split all geometric entities according to the specified ball.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to split. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

BALL CENTER

Specify the center of the ball in the **x**, **y**, and **z** (only in 3D) fields (SI unit: m).

BALL RADIUS

Specify the radius of the ball in the **Radius** field (SI unit: m). The default radius is 1.

CONDITION

Use the **Include element if ball contains** list to select the condition for which the element is enclosed in the specified ball. Choose **All vertices** to consider an element to be enclosed in the specified ball if all element vertices are enclosed, or choose **Some vertex** to consider it enclosed if at least one element vertex is enclosed.

Box

Use a **Box** node () to split geometric entities of an imported mesh by creating at least one new geometric entity for the elements enclosed in the specified box.

To add a Box node, right-click a 2D or 3D mesh node and select **Box** from the **Partitions** menu. Then use the following sections to specify the geometric entities to split, the properties of the box, and the split condition:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to split. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to split all geometric entities according to the specified box.
- Choose **Domain, Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to split. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

BOX LIMITS

Specify the limits of the box in the **x minimum**, **x maximum**, **y minimum**, **y maximum**, **z minimum** (3D only), and **z maximum** (3D only) fields.

CONDITION

Use the **Include element if box contains** list to select the condition for which an element is enclosed in the specified box. Choose **All vertices** to consider an element to be enclosed in the specified box if all element vertices are enclosed, or choose **Some vertex** to consider it enclosed if at least one element vertex is enclosed.

Create Vertex

Use a **Create Vertex** node () to create an additional vertex in the closest mesh point to a specified position of an imported mesh.

To add a Create Vertex node, right-click a 2D or 3D mesh node and select **Create Vertex**. Then use the following section to specify the position of the new vertex:

CREATE VERTEX CLOSEST TO POINT

Use the **x**, **y**, and **z** (3D only) fields to specify the position of the vertex. The vertex appears in the mesh point closest to the specified position.

Cylinder

Use a **Cylinder** node () to split geometric entities of an imported mesh by creating at least one new geometric entity for the elements enclosed in the specified cylinder.

To add a Cylinder node, right-click a 3D mesh node and select **Cylinder** from the **Partitions** menu. Then use the following sections to specify the geometric entities to split, the properties of the cylinder, and the split condition:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to split. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to split all geometric entities according to the specified cylinder.
- Choose **Domain, Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to split. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

SIZE AND SHAPE

Specify the radius of the cylinder in the field **r** and the positions of the upper and lower boundary circles in the **Top distance** and **Bottom distance** fields, respectively.

POSITION

Specify the position of cylinder in the **x**, **y**, and **z** fields.

AXIS

Use **Axis type** to set the direction of the cylinder axis. Choose **x-axis**, **y-axis**, or **z-axis** to let the cylinder axis coincide with one of the coordinate axes. It is also possible to customize the cylinder axis by choosing **Cartesian** or **Spherical** and using **x**, **y**, and **z**, or **theta** and **phi**, respectively.

CONDITION

Use the **Include element if cylinder contains** list to select the condition for an element to be enclosed in the specified cylinder. Choose **All vertices** to consider an element to be enclosed in the specified cylinder if all element vertices are enclosed, or choose **Some vertex** to consider it enclosed if at least one element vertex is enclosed.

Delete Entities

Use a **Delete Entities** node () to delete geometric entities from an imported mesh.

To add a Delete Entities node, right-click a 2D or 3D mesh node and select **Delete Entities**. Then use the following sections to specify the geometric entities to delete:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to delete. You choose the geometric entity level from the **Geometric entity level** list: Choose **Domain**, **Boundary**, **Edge**, or **Point** to specify the domains, boundaries, edges, or vertices, respectively, that you want to delete. Use **All domains**, **All boundaries**, **All edges**, or **All points** to select all entities of the specified dimension.

ADJACENT ENTITIES

Select the **Delete adjacent lower dimensional entities** check box to also delete the adjacent entities of lower space dimensions.

Detect Faces

Use a **Detect Faces** node () to split geometric boundary entities of an imported mesh by searching for shapes in the mesh that are likely to constitute faces.

To add a **Detect Faces** node, right-click a 3D Mesh node and select **Detect Faces** from the **Partitions** submenu. Then use the following sections to specify the geometric boundary entities to split and the parameters of the partitioning algorithm:

BOUNDARY SELECTION

Select the geometric boundary entities that you want to split. Use **All boundaries** to select all boundary entities.

FACE PARTITIONING

The partitioning algorithm splits the boundary elements along edges where the angle between neighboring boundary elements is large. Use the **Maximum face neighbor angle** field to set the largest tolerated neighbor angle.

Select the **Detect planar faces** check box (selected by default) to also group approximately planar boundary elements into faces. Use the **Minimum relative area** field to limit how small these faces can be relative to all of the selected boundary entities. The maximum accepted angle between boundary elements in a planar face can be set with the **Maximum neighbor angle** field. If the **Detect adjacent fillet faces** check box is selected, the algorithm also searches for adjacent groups of boundary elements that form cylindrical faces.

Finalize

The **Finalize** node ends a meshing sequence of imported type. It performs an associativity update for geometric entity numbers. You cannot delete, disable, or move the **Finalize** node. The software automatically builds all nodes in a meshing sequence, including the **Finalize** node, if you select a node in Model Builder outside the meshing sequence.

Import

Use an **Import** node () to import a mesh from a file or from another meshing sequence or mesh part. It is only possible to import a mesh to a meshing sequence under a **Mesh** node if the geometry sequence is empty. If the sequence already contains a mesh, the imported mesh is added to the existing mesh, forming an assembly. If you use this **Import** node in a mesh part, you can then use it in a geometry sequence through an **Import** node under a **Geometry** node.

To import a mesh, right-click a **Mesh** node or a **Mesh Part** node and select **Import**. Then enter the properties for the import using the following section:

IMPORT

In the **Source** list, choose the type of data to import: **Any importable file**, **Meshing sequence**, and **COMSOL Multiphysics file** are always available. In addition, you can choose **STL/VRML file** in 3D and **NASTRAN file** in 2D and 3D.

For file import, specify the filename in the **Filename** field or click the **Browse** button. For import from another mesh in the model, select the meshing sequence from the **Source** list below. To import a meshing sequence, click the **Import** button. For a mesh part, the **Import** button is not needed and is therefore disabled. If you have changed some property, the software automatically re-imports the mesh when you click a build button.

For information on remeshing an imported mesh, see [Creating Geometry from Mesh](#).

Properties for COMSOL Multiphysics Import

In 3D, you can import 3D meshes and planar 2D meshes from COMSOL Multiphysics files (**.mphtxt** or **.mphbin**). Planar 2D meshes, imported to a 3D component, always appear at $z = 0$.

When you import a mesh from a COMSOL Multiphysics file that contains mesh selections, you need to select the **Import selections** check box to import the selections together with the mesh. If you choose to import mesh selections, corresponding selections are created and appear in the **Domain Selections**, **Boundary Selections**, **Edge Selections**, or **Point Selections** sections, depending on space dimension and the entity level for the imported selections. You can use the imported selections, for example, to add as a selection to a data set or plot during postprocessing. See also [Domain Selections](#), [Boundary Selections](#), [Edge Selections](#), and [Point Selections](#) below.

To import the second-order elements in 2D and 3D as linear elements (that is, ignoring node points not in element vertices), select the **Import as linear elements** check box (not selected by default).

Properties for NASTRAN Import

You can import 3D meshes (and planar 2D meshes) in the NASTRAN bulk data format, the most common format for exchanging 3D meshes among programs. This format supports hundreds of NASTRAN entries describing elements, loads, and materials, making it possible to define a complete finite element model. When you import a NASTRAN bulk data file into COMSOL Multiphysics, the software imports mesh and material information only.

To import mesh and material data from a NASTRAN file, select **Mesh and materials** in the **Data to import** list. In this case, COMSOL Multiphysics creates **Material** nodes corresponding to the data in any MAT1 and MAT10

entries in the file. Furthermore, the thickness data of any PSHELL entry in the file is stored in a **Variables** node as long as it is greater than zero. To simplify the use of this data in physics interfaces, such as the **Shell** interface, an **Explicit** selection, which contains all boundary faces associated with PSHELL entries, also becomes available. If the material data is not required, select **Only mesh** to import the mesh only.

Mesh information is read from different NASTRAN entries, including those for mesh elements of lower dimension. When this information is not complete in the file, COMSOL Multiphysics enriches the imported mesh data with boundary elements, edge elements, and vertex elements such that a valid mesh object is formed. Each element in the imported mesh object receives a unique entity index.

For information on the NASTRAN entries that COMSOL Multiphysics supports, see [Import](#) in the *COMSOL Multiphysics Programming Reference Manual (Meshing)*.

To use material data in the file to determine the partitioning of the elements, select the **Partition according to material data** check box (selected by default). Choose **Create selections** to automatically generate selections corresponding to the groups of domain and boundary elements in the file. If you do this, corresponding selections are created and appear in the **Domain Selections** or **Boundary Selections** sections, depending on the entity level for the imported selections. These selections become available for specifying geometric entities throughout the component — for instance, in Material nodes and physics interfaces. Choose **Allow partitioning of shells** to allow the boundary partitioning algorithm to split the boundary entities that are defined based on the data in the file into smaller parts. Both options are selected by default.

The import of NASTRAN files supports first-order (linear) and second-order elements. To import the second-order elements in the NASTRAN file as linear elements (that is, ignoring node points not in element vertices), select the **Import as linear elements** check box (not selected by default).

Boundary Partitioning Properties

These settings are available with the following options from the **Source** list: **COMSOL Multiphysics file**, **STL/VRML file**, and **NASTRAN file**.

If the partitioning of the boundary elements in the mesh to import into boundaries (faces) is not complete, you can use the **Boundary partitioning** list to control the partitioning:

- Select **Automatic** to let the software partition the boundary elements into boundaries automatically (the default setting).
- Select **Minimal** to make a minimal boundary partitioning. This is useful when you import a mesh from a measured geometry or a NASTRAN mesh with a predefined boundary partitioning. The automatic face partitioning is not desired then.
- Select **Manual** (in 2D) or **Detect boundaries** (in 3D) to manually control the partitioning. Both choices add a set of parameters, which make it possible to influence the result of the partitioning algorithm; for the Detect boundaries case in 3D, the **Detect Faces** and **Detect Edges** sections appear, containing settings for controlling the face and edge partitioning, respectively.

Repair Tolerance for STL Files

The **Repair tolerance** list is available when the **Source** list is set to **STL/VRML file**. The repair tolerance assures that the imported mesh contains no holes and no triangles with sides shorter than the tolerance. From the Repair tolerance list, select one of these options:

- **Automatic** (the default), to use a default tolerance value (10^{-8}).
- **Relative**, to specify a **Relative tolerance** (default: 10^{-8}). The relative tolerance value must be smaller or equal to 1.
- **Absolute**, to specify an **Absolute tolerance** (default: 10^{-8}).

DETECT FACES (3D) AND 2D SETTINGS

The partitioning algorithm aims to split boundary elements (edge elements in 2D, face elements in 3D) into boundary entities in such a way that no large angles appear between neighboring elements within the same boundary entity. In 2D, you can limit the angle between any two elements within the same boundary entity using the **Maximum angle within boundary** field. The maximum accepted neighbor angle can be set using the **Maximum face neighbor angle** field (default: 40 degrees).

If the **Detect planar faces** check box (3D) or the **Detect straight edges** check box (2D) is selected (both are selected by default), the mesh import detects (approximately) planar faces or straight edges, respectively. The minimum size of a straight or planar boundary entity, relative to the entire boundary, can be set using the **Minimum relative length** field (2D) and **Minimum relative area** field (3D). The maximum accepted angle (in degrees) between elements for a boundary to be considered straight or planar can be set using the **Maximum neighbor angle** field. If the **Detect adjacent fillet faces** check box (3D) is selected, the algorithm also searches for adjacent groups of boundary elements that form cylindrical faces.

DETECT EDGES (3D)

The partitioning algorithm aims to split edge elements into edge entities in such a way that no large angles appear between neighboring elements within the same edge entity. The maximum accepted neighbor angle can be set using the **Maximum edge neighbor angle** field (default: 60 degrees).

If the **Detect planar edges** check box is selected (it is selected by default), the mesh import detects (approximately) planar edges. The **Detection parameter** specifies to which extent the operation should search for planar edges. Use the slider to tune the detection level, where **Strict** means that only fully planar edges are searched for, and **Tolerant** means that the algorithm searches for planar edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

If the **Detect straight edges** check box is selected (it is selected by default), the mesh import detects (approximately) straight edges. The **Detection parameter** specifies to which extent the operation should search for straight edges. Use the slider to tune the detection level, where **Strict** means that only fully straight edges are searched for, and **Tolerant** means that the algorithm searches for straight edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

From the **Minimum edge length** list, choose one of the following options: **Automatic** (the default), **Relative**, or **Absolute** to specify the minimum required length of an edge to be detected. If you select **Relative**, specify a minimum relative length in the **Minimum relative length** field that appears, and if you select **Absolute**, specify a minimum absolute length in the **Minimum absolute length** field that appears.

DOMAIN SELECTIONS, BOUNDARY SELECTIONS, EDGE SELECTIONS, AND POINT SELECTIONS

In these sections, imported mesh selection appear. In the **Name** column, the name of each selection appears. For COMSOL Multiphysics file import, each name is by default the name of the selection in the imported file, which appears in the **Name in file** column. Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

Join Entities

Use a **Join Entities** node () to join adjacent geometric entities in an imported mesh.

To add a Join Entities node, right-click a 2D or 3D mesh node and select **Join Entities**. Then use the following sections to specify the geometric entities to join:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to join. You choose the geometric entity level from the **Geometric entity level** list: Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to join. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

ADJACENT ENTITIES

Select the **Join adjacent lower dimensional entities** check box to also join the adjacent entities of lower dimensions (boundaries and edges for joined domains, for example).

Logical Expression

Use a **Logical Expression** node () to split geometric entities of an imported mesh by creating at least one new geometric entity for the elements that fulfill the specified logical expression.

To add a Logical Expression node, right-click a 2D or 3D mesh node (that has an imported mesh) and select **Logical Expression** from the **Partitions** menu. Then use the sections below to specify the geometric entities to split, the expression, and the split condition.

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to split. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to split all geometric entities according to the specified cylinder.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to split. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

EXPRESSION

Enter a logical expression using **x**, **y**, or **z** (3D only), [Unary, Binary, and List Operators and Their Precedence Rules](#), and [Mathematical and Numerical Constants](#). For instance, the expression $(x*x+y*y)<1$ defines a ball split in 2D and an infinite cylinder split in 3D. You can also use the Boolean variables **istri**, **isquad**, **istet**, **ispqr**, **isprism**, or **ishex** in the expression in order to partition the mesh according to the respective element type (triangular, quadrilateral, tetrahedral, pyramid, prism, or hexahedral, respectively). For instance, the expression **istet** makes a separate domain for each connected set of tetrahedra, while the expression **ispqr || ishex** makes a separate domain for each connected set of elements containing pyramids or hexahedra.

By default, the expression is set to 1, not inducing any split of geometric entities.

CONDITION

Use the **Include element if expression is fulfilled for** list to select the condition for which the logical expression is fulfilled for an element. Choose **All vertices** to make an element satisfy the expression if it is true for all element vertices, or choose **Some vertex** if it is true for at least one element vertex.

Meshing Examples

Generating a 3D Swept Mesh

Figure 8-11 shows the 3D **Swept** mesh for a simple geometry but with a layered structure typical for printed circuit boards or MEMS geometries. In such cases, the swept mesh generation presents an alternative to using a free tetrahedral meshing.

If you have the:

- Acoustics Module, see *Vibrations of a Disk Backed by an Air-Filled Cylinder*: Application Library path **Acoustics_Module/Verification_Examples/coupled_vibrations**.
- Batteries & Fuel Cells Module, see *Ohmic Losses and Temperature Distribution in a Passive PEM Fuel Cell*: Application Library path **Batteries_and_Fuel_Cells_Module/Thermal_Management/passive_pem**.
- Electrodeposition Module, see *Electrodeposition of an Inductor Coil*: Application Library path **Electrodeposition_Module/Tutorials/inductor_coil**.
- Chemical Reaction Engineering Module, see *Steam Reformer*: Application Library path **Chemical_Reaction_Engineering_Module/Reactors_with_Porous_Catalysts/steam_reformer**.

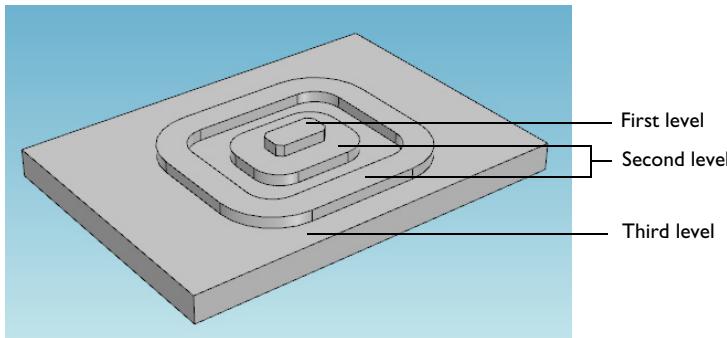

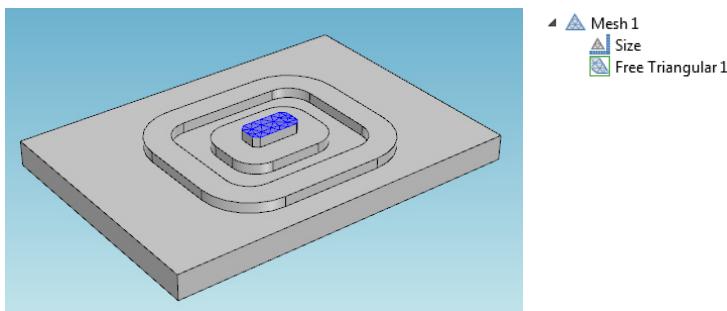

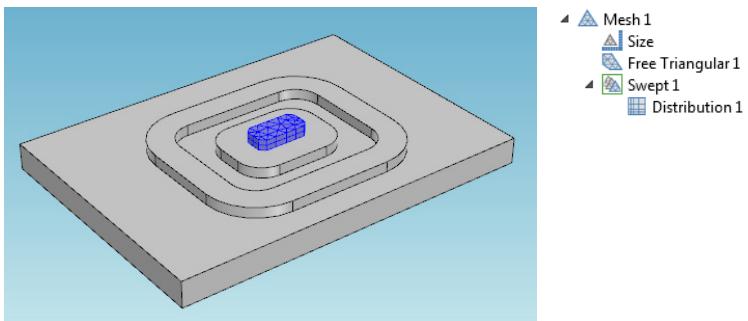

Figure 8-11: An example of the layered geometry used for creating a swept mesh.

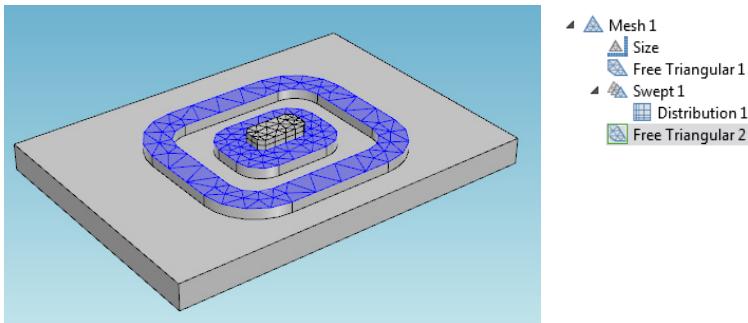

- 1 Add a **Free Triangular** () node from the **Mesh** toolbar, **Boundary** menu () (or right-click the **Mesh** node and select it from the **More Operations** menu.)
- 2 Add the first level boundary to the selection list (see Figure 8-11 for an example of a suitable geometry).
- 3 Click **Build Selected** (). The mesh below displays.

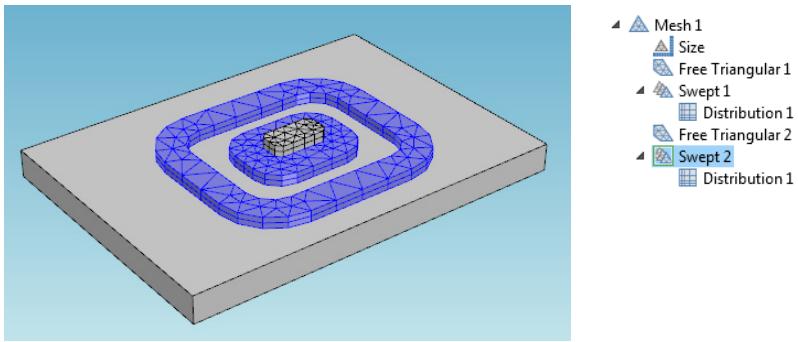

- 4 Add a **Swept** (▲) node from the **Mesh** toolbar.
- 5 Select the domain in the first level.
- 6 Add a **Distribution** (■) node to the **Swept 1** node.
- 7 Enter the **Number of elements** in the field (for example, 2).
- 8 Click **Build Selected** (■).

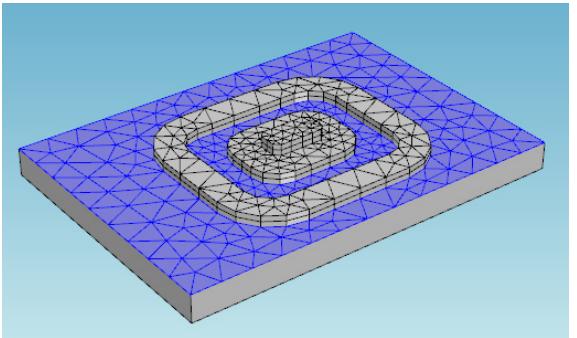

- 9 Add a second **Free Triangular** (▲) node from the **Mesh** toolbar.
- 10 Select the boundaries at the second level and click the **Build Selected** button (■).

- II Repeat the same swept operations for the first level domains but now for the second level. Add the second **Swept** and **Distribution** nodes.

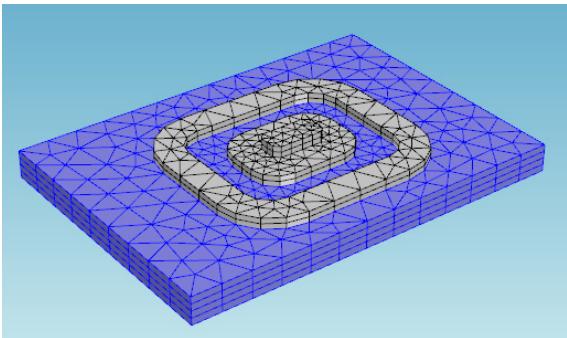

I2 Add a third **Free Triangular** mesh operation to mesh the third level boundaries.

- ▲ Mesh 1
- ▲ Size
- ▲ Free Triangular 1
- ▲ Swept 1
 - Distribution 1
 - Free Triangular 2
- ▲ Swept 2
 - Distribution 1
 - Free Triangular 3

I3 Mesh the third level domain. Use the **Swept** mesh operation and enter 4 for the **Number of elements** in the corresponding **Distribution** attribute.

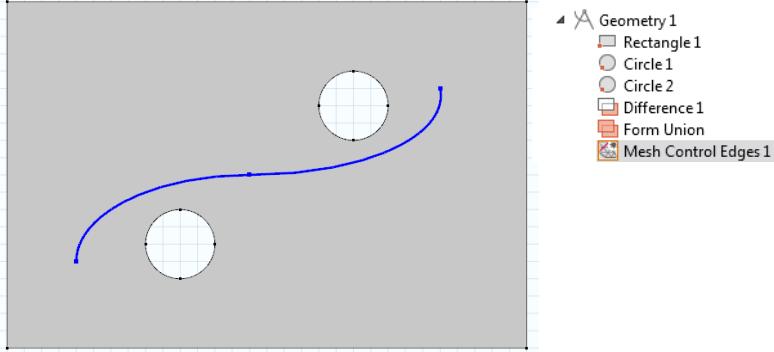

- ▲ Mesh 1
- ▲ Size
- ▲ Free Triangular 1
- ▲ Swept 1
 - Distribution 1
 - Free Triangular 2
- ▲ Swept 2
 - Distribution 1
 - Free Triangular 3
- ▲ Swept 3
 - Distribution 1

The meshing sequence displayed in the **Model Builder** makes it possible to return to your attribute settings and change mesh sizes and distributions. After making any changes, click the **Build All** button () or press F8 to rebuild the entire meshing sequence.

Using Mesh Control Entities to Control Element Size

Figure 8-12 shows a 2D geometry with two holes and a Bézier Polygon that is intended not to be a part of the model but is included only to control mesh size inside the domain. This example is about **Mesh Control Entities** and uses a simple geometry.

- I** Add a **Mesh Control Edges** () node from the **Geometry** toolbar, **Virtual Operations** menu () (or right-click the **Geometry** node and select it from the **Virtual Operations** submenu).
- 2** Select the edges of the Bézier Polygon in the **Edges to include** selection.

- ▲ Geometry 1
 - Rectangle 1
 - Circle 1
 - Circle 2
 - Difference 1
 - Form Union
 - Mesh Control Edges 1

Figure 8-12: A geometry with a Bézier Polygon used to define mesh size inside the domain.

- 3 Click **Build Selected** (). Note that the selected edges are removed.
- 4 Add a **Free Triangular** () node from the **Mesh** toolbar. Note that the edges removed in the previous step are now visible again.
- 5 Add a **Size** () node to **Free Triangular 1**.
- 6 Select Boundary as the Geometric entity level and select the edges of the Bézier Polygon.
- 7 Select **Extra fine** as the **Predefined** element size.
- 8 Click the **Build All** button () or press F8 to build the entire mesh. Note that the edges of the Bézier Polygon are now removed (Figure 8-13) and that the only trace of them is the fine mesh size inside the domain.

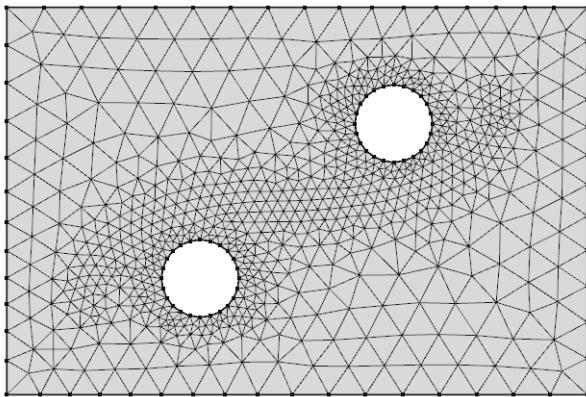

Figure 8-13: Fine mesh inside the domain.

MESH CONTROL FEATURE MODEL EXAMPLES

For an example of the Mesh Control Edges feature:

- If you have the CFD Module, see *Turbulent Flow Over a Backward Facing Step*: Application Library path **CFD_Module/Single-Phase_Benchmarks/turbulent_backstep**.
- If you have the Heat Transfer Module, see *Turbulent Flow Over a Backward Facing Step*: Application Library path **Heat_Transfer_Module/Verification_Examples/turbulent_backstep**.

For an example of the Mesh Control Faces feature:

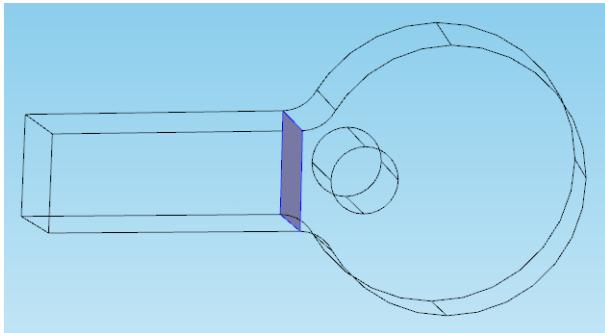

- If you have the Batteries & Fuel Cells Module, see *Thermal Modeling of a Cylindrical Lithium-ion Battery in 3D*: Application Library path **Batteries_and_Fuel_Cells_Module/Thermal_Management/li_battery_thermal_3d**.
- If you have the CFD Module, see *Airflow Over an Ahmed Body*: Application Library path **CFD_Module/Single-Phase_Benchmarks/ahmed_body**.

Using Structured and Unstructured Mesh with Boundary Layers

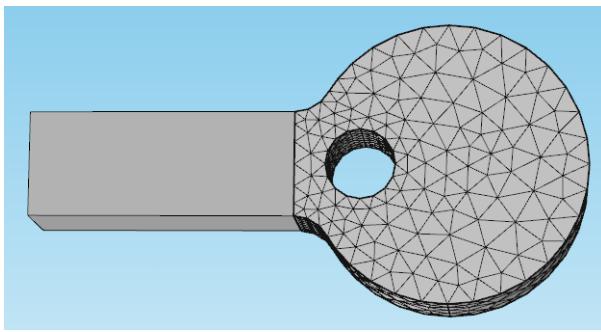

This example demonstrates a geometry where free tetrahedral mesh is used in one domain and a swept mesh is used in another domain. The domains are separated by a mesh control face, which is automatically removed once the domains on both sides are meshed. Finally boundary layers are added, without the need to respect the (now removed) mesh control face.

- I Add a **Mesh Control Faces** () node from the **Geometry** toolbar, **Virtual Operations** menu () (or right-click the **Geometry** node and select it from the **Virtual Operations** submenu).

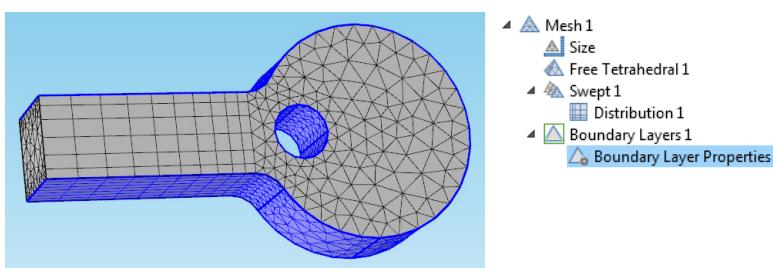

- 2 Select the face separating the domains in the **Faces to include** selection using the scroll wheel for selecting the interior boundary.

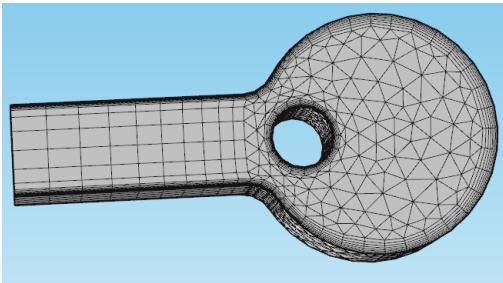

- 3 Click **Build Selected** (). The face is removed. There is now only one domain.
 4 Add a **Free Tetrahedral** () node from the **Mesh** toolbar. Note that the face has reappeared and that there are two domains.
 5 Add the cylinder-shaped domain with a hole to the selection list.
 6 Click the **Size** () node and select **Finer** as the **Predefined** element size. Click **Build Mesh** ().

- 7 Add a **Swept** () node from the **Mesh** toolbar.
 8 Add a **Distribution** () node to **Swept 1** from the **Mesh** toolbar.
 9 Select **Predefined distribution type** and enter 10 in the **Number of elements** field and 3 in the **Element ratio** field. Click **Build Mesh** ().
 10 Add a **Boundary Layers** () node from the **Mesh** toolbar.
 II In the **Model Builder**, click the **Boundary Layer Properties** () node under **Boundary Layers 1**.
 I2 Add (for example) the sides of the geometry to the selection list

I3 Click the **Build Mesh** button () or press F8 to build the entire mesh. The mesh control face is now removed and the boundary layer mesh nodes are not located where the boundary was.

BOUNDARY LAYER MESHING MODEL EXAMPLES

For an example of the Boundary Layer and Boundary Layer Properties features:

- If you have the AC/DC Module, see *Iron Sphere in a 20 kHz Magnetic Field*: Application Library path [**ACDC_Module/Tutorials/iron_sphere_20khz_bfield**](#).
- If you have the Acoustics Module, see *Acoustic Scattering off an Ellipsoid*: Application Library path [**Acoustics_Module/Tutorials/acoustic_scattering**](#).
- If you have the Batteries & Fuel Cells Module, see *Liquid-Cooled Lithium-Ion Battery Pack*: Application Library path [**Batteries_and_Fuel_Cells_Module/Thermal_Management/li_battery_pack_3d**](#).
- If you have the CFD Module, see *Turbulent Flow Over a Backward Facing Step*: Application Library path [**CFD_Module/Single-Phase_Benchmarks/turbulent_backstep**](#).
- If you have the Chemical Reaction Engineering Module, see *Dissociation in a Tubular Reactor*: Application Library path [**Chemical_Reaction_Engineering_Module/Thermodynamics/dissociation**](#).
- If you have the Electrochemistry Module, see *Wire Electrode*: Application Library path [**Electrochemistry_Module/Electrochemical_Engineering/wire_electrode**](#).
- If you have the Heat Transfer Module, see *Turbulent Flow Over a Backward Facing Step*: Application Library path [**Heat_Transfer_Module/Verification_Examples/turbulent_backstep**](#).
- If you have the Plasma Module, see *3D ICP Reactor, Argon Chemistry*: Application Library path [**Plasma_Module/Inductively_Coupled_Plasmas/argon_3d_icp**](#).

Materials

This chapter includes information about how to work with materials in models and describes the material databases included with COMSOL Multiphysics® and the add-on modules.

Materials Overview

About Materials and Material Properties

MATERIALS

In COMSOL Multiphysics models, you can add one or more *materials*, which are named collections of *material properties*. Each such material is represented by a **Material** node (). Each material includes a number of physical properties with the values or functions (for temperature-dependent material properties, for example) that describe the material.

When you add a material from a material database or the Material Library, the **Model Builder** node label is copied from the library — for example, **Copper** or **Air**. When you add a **Blank Material**, the default node label is **Material** followed by a number. At any time press F2 to rename a node. The **Settings** window is always called **Material**, irrespective of the current node label. Also see [The Settings Window for Material](#).

MATERIAL PROPERTIES AND PROPERTY GROUPS

The material properties are organized in material *property groups*, which appear as subnodes under the **Material** node in the **Model Builder**:

- The **Basic** property group contains common material properties that can generally be measured and are meaningful without any context.
- User-defined groups may contain a subset of the same quantities.
- Each predefined property group contains one or more material properties that are only meaningful together and in the context of a particular material model.
- The material property values are outputs of the material, which can be constant values or functions of *model inputs* (physical quantities like temperature and pressure). In principle, the physics interfaces first ask a material which inputs it requires to compute its output properties, then ask the material to compute property values given values of the model inputs — for example, thermal conductivity (output) as function of temperature (input). See [About Model Inputs](#).
- Each property group can also define a set of local properties and functions that can be used together with model inputs in output property expressions. This makes it possible to, for example, create generic materials for certain classes of some type of material and use the local properties to parameterize the material.

About the Material Databases

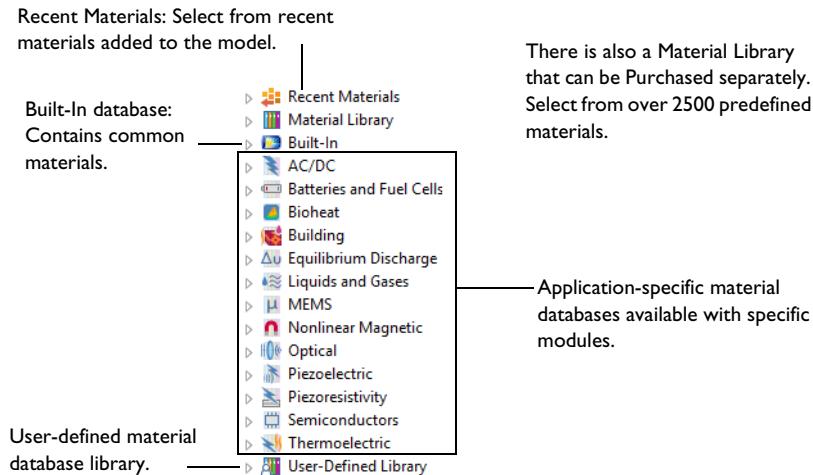

Figure 9-1: Use the Material Browser to select predefined materials in all applications.

All COMSOL Multiphysics modules have predefined material data available in collections of materials — material databases — to build models. The most extensive material data is contained in the separately purchased Material Library, but all modules contain commonly used or module-specific collections of materials. For example, the Built-In database is available to all users but the MEMS database is included with the MEMS Module and Structural Mechanics Module. You can also create custom materials and material libraries by researching and entering material properties.

The **Material Browser** window provides access to all material databases (including the Material Library). The following material databases are available in the Material Browser (some require additional module licenses):

- *Recent Materials:* From the **Recent Materials** folder (Recent Materials icon), select from a list of recently used materials with the most recent at the top. This folder is available after the first time a material is added to a Component node.
- *Material Library.* An optional add-on database, the **Material Library**, contains data for over 2500 materials and 20,000 property functions.
- *Built-In.* Included with COMSOL Multiphysics, the **Built-In** database contains common materials with primarily electrical, structural, and thermal properties. The materials in this database can be considered as examples of common materials with typical values for their material properties. The *Air* and *Water, liquid* materials use the same temperature- and pressure-dependent property values as the corresponding values in the [Liquids and Gases Materials Database](#).
- *AC/DC.* Included in the AC/DC Module, the **AC/DC** database has electric properties for some magnetic and conductive materials.
- *Batteries and Fuel Cells.* Included in the Batteries & Fuel Cells Module, the **Batteries and Fuel Cells** database includes properties for electrolytes and electrode reactions for certain battery chemistries.
- *Bioheat:* Included in the Heat Transfer Module, the **Bioheat** database includes properties for several biological tissues such as bone, fat, human and porcine liver, lung, muscle, myocardium, prostate, and skin.
- *Building:* Included in the Heat Transfer Module, the **Building** database includes hygroscopic and thermal properties for several materials used for structure, sheathing, thermal isolation, and vapor barrier in buildings.
- *Equilibrium Discharge:* Included in the Plasma Module.

- *Liquids and Gases*: Included in the Acoustics Module, CFD Module, Batteries & Fuel Cells Module, Chemical Reaction Engineering Module, Heat Transfer Module, MEMS Module, Microfluidics Module, Pipe Flow Module, and Subsurface Flow Module, the **Liquids and Gases** database includes transport properties and surface tension data for liquid/gas and liquid/liquid interfaces.
- *MEMS*: Included in the MEMS Module and Structural Mechanics Module, the **MEMS** database has properties for MEMS materials: metals, semiconductors, insulators, and polymers.
- *Nonlinear Magnetic*: Included in the AC/DC Module, the **Nonlinear Magnetic** database has properties, such as nonlinear magnetization curves, for a large set of ferromagnetic alloys like various types of steel.
- *Optical*: Included with the Ray Optics Module and Wave Optics Module, the **Optical** database contains frequency-dependent refractive index properties for organic and inorganic materials, glasses, and other materials such as semiconductors.
- *Piezoelectric*: Included in the Acoustics Module, MEMS Module, and Structural Mechanics Module, the **Piezoelectric** database has properties for piezoelectric materials.
- *Piezoresistivity*: Included in the MEMS Module, the **Piezoresistivity** database has properties for piezoresistive materials, including p-type and n-type silicon materials.
- *RF*: Included in the RF Module, the **RF** database includes a number of substrate materials that assist in modeling RF components.
- *Semiconductors*: Included in the Semiconductor Module, the Semiconductors database contains silicon, germanium, gallium arsenide, $\text{Al}_x\text{Ga}_{1-x}\text{As}$, gallium nitride (wurtzite and zincblende structures), gallium phosphide, gallium antimonide, indium arsenide, indium phosphide, and indium antimonide materials for use with this module.
- *Thermoelectric*: Included with the Heat Transfer Module and contains bismuth telluride and lead telluride materials for use with the Thermoelectric Effect interface.
- *User-Defined Library*: The **User-Defined Library** folder () is where user-defined material databases (libraries) are created. When you have created a new database, it also displays in the **Material Browser**.

The material databases shipped with COMSOL Multiphysics are read-only. This includes the Material Library and any materials shipped with the optional modules.

About Using Materials in COMSOL Multiphysics

USING THE MATERIALS IN THE PHYSICS SETTINGS

The physics setup in a model is determined by a combination of settings in the **Materials** and physics nodes. When the first material is added to a Component node, COMSOL Multiphysics automatically assigns that material to all domains in the geometry (or all boundaries or edges if the Component only contains surfaces or edges). Different

geometric entities can have different materials. The following example uses the *heat_sink.mph* model file contained in the Heat Transfer Module and CFD Module Applications Libraries.

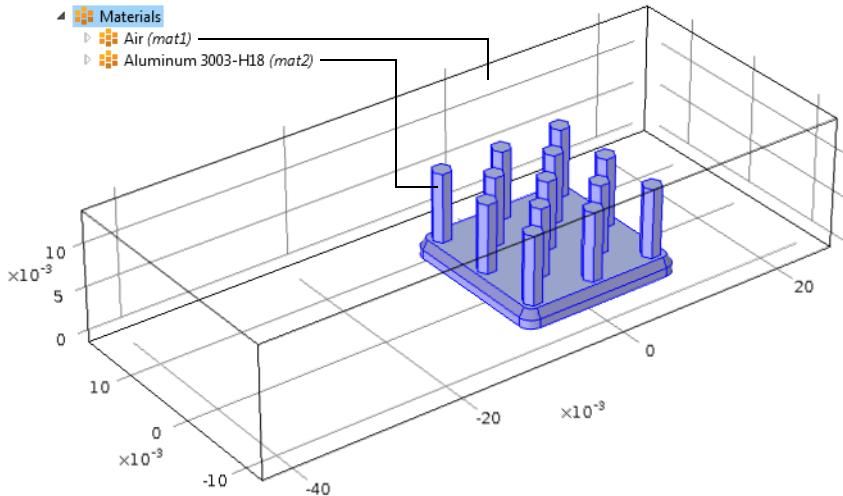

Figure 9-2: Assigning materials to a heat sink model. Air is assigned as the material to the box surrounding the heat sink, and aluminum to the heat sink itself.

If a geometry consists of a heat sink in a container, **Air** can be assigned as the material in the container surrounding the heat sink and **Aluminum** as the heat sink material itself (see [Figure 9-2](#)). The **Conjugate Heat Transfer** interface, selected during model setup, uses a **Fluid** model to simulate nonisothermal flow, with heat transfer by convection and conduction, in the box surrounding the heat sink, and a **Heat Transfer in Solids** model to simulate heat conduction in the heat sink. The **Heat Transfer in Solids I** settings use the material properties associated to the **Aluminum 3003-H18** materials node, and the **Fluid I** settings define the flow using the **Air** material properties. The other nodes under **Conjugate Heat Transfer** define the initial and boundary conditions.

All physics node properties automatically use the correct material properties from the **Material** nodes when the default **From material** setting is used. This means that one node can be used to define the physics across several domains with different materials; the COMSOL Multiphysics software then uses the material properties from the different materials to define the physics in each domain.

The Settings Window for Material

There are also some physics nodes where you can explicitly select a material from which material properties are retrieved (for example, the **Settings** window for **Fluid Properties** for two-phase flow modeling). The default setting is then typically to use the **Domain material** on each domain (that is, the materials defined on the same domains as the physics that uses the material data). In addition to the **Domain material**, you can select any other material that is present in the Component, regardless of its selection. The selected material's properties are then applied to all domains in the feature's selection.

EVALUATING AND PLOTTING MATERIAL PROPERTIES

You can access the material properties for evaluation and plotting like other variables in a model using the following variable naming conventions and namespaces:

- To access a material property throughout the model (across several materials) and not just in a specific material, use the special material namespace `root.material`. For example, `root.material.rho` is the density ρ as

defined by the materials in each domain in the geometry. For plotting, you can type the expression `material.rho` to create a plot that shows the density of all materials. This shorthand syntax is available for materials in the Basic (def) material property group, but you can also access the density in the Basic material property group namespace as `material.def.rho`.

- For an anisotropic property such as the electrical conductivity, its values are available as `material.def.sigma11`, `material.def.sigma12`, and so on. If such a property is set as isotropic for some material, `material.def.sigma_iso` represents that isotropic value.
- For properties in property groups other than the Basic (def) group, the full namespace must be used, including the property group name. For example, to access the initial yield stress `sigmags` for elastoplastic materials in the Elastoplastic Material Model property group, use `material.ElastoplasticModel.sigmags`.

If you use a temperature-dependent material, each material contribution asks for a special model input. For example, `rho(T)` in a material `mat1` asks for `root.mat1.def.T`, and you need to define this variable (`T`) manually — if the temperature is not available as a dependent variable — to make the density variable work.

- To access a material property from a specific material, you need to know the names for the material and the property group. Typically, for the first material (Material 1) the name is `mat1` and most properties reside in the default **Basic** property group with the name `def`. The variable names appear in the **Variable** column in the table under **Output properties** in the **Settings** window for the property group; for example, `Cp` for the heat capacity at constant pressure. The syntax for referencing the heat capacity at constant pressure in Material 1 is then `mat1.def.Cp`. Some properties are anisotropic tensors, and each of the components can be accessed, such as `mat1.def.k11`, `mat1.def.k12`, and so on, for the thermal conductivity. The numbers 1, 2, and 3 denote the first, second, and third direction, respectively, in the active coordinate system. In the general case, you can define a 3-by-3 tensor, for example, k_{ij} in the order $k_{11}, k_{21}, k_{31}, k_{12}, k_{22}, k_{32}, k_{13}, k_{23}$, and k_{33} . For material properties that are functions, call these with input arguments such as `mat1.def.rho(pA, T)` where `pA` and `T` are numerical values or variables representing the absolute pressure and the temperature, respectively. Functions can be plotted directly from the function nodes' **Settings** window by first specifying suitable ranges for the input arguments. If a possibly anisotropic property is defined as isotropic, you can access its value as `mat1.def.k_iso`, for example.
- Material Link nodes define all properties of the current source material in the Material Link's namespace. For example, for the node **Material Link 1 (matlnk1)**, the density of the currently selected source material is available as `matlnk1.def.rho`.
- Material Switch nodes define variables similarly to Material Link nodes. For example, during a material sweep over the children of **Switch 1 (sw1)**, you can access the density of the material used in the current sweep step as `sw1.def.rho`.
- Many physics interfaces also define variables for the material properties that they use. For example, `solid.rho` is the density in the Solid Mechanics interface and is equal to the density in a material when it is used in the domains where the Solid Mechanics interface is active. If you define the density in the Solid Mechanics interface using another value, `solid.rho` represents that value and not the density of the material. If you use the density from the material everywhere in the model, `solid.rho` and `material.rho` are identical.
- To see the domain groups (that is, groups of domains with equal material settings), the variable `root.material.domain` — and, for lower-dimensional entities when applicable, `root.material.boundary`, `root.material.edge`, and `root.material.point` — is available and evaluates to unique integer values for each domain group.

THE MATERIAL TYPE SECTION

The **Material type** setting, available on some physics node **Settings** windows, decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Non-solid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

The Settings Window for Material

Working with Materials

The Material Browser Window

The **Material Browser** window () contains a number of databases with a broad collection of elastic, solid mechanics, electromagnetic, fluid, chemical, thermal, piezoelectric, and piezoresistive properties of materials. The number of material databases depends on which COMSOL products your license includes. See [About the Material Databases](#) for information about available material databases. Use the Material Browser to find predefined materials and add them to the Model Builder, or create a custom material library.

	To open the Material Browser  :
	<ul style="list-style-type: none">On the Materials toolbar, click Browse Materials.Right-click the Materials node (), and then select Browse Materials.From the Home toolbar, select Windows>Material Browser.
 	To open the Material Browser  :
	<ul style="list-style-type: none">On the Model Toolbar, click Browse Materials.Right-click the Materials node (), and then select Browse Materials.Select Windows>Material Browser.

The **Material Browser** is similar to [The Add Material Window](#) but it includes detailed property information about each material. From this window you can also create a new material library and import a material library. See [Adding Materials to a Component](#) for information about adding materials to your model's components (geometries). Click **Done** () to close the **Material Browser** and add the materials in the **Added to model** list to the model. Click **Cancel** (), press Escape, or click in the main toolbar to exit the **Material Browser** without adding any materials.

You can browse all of the available material databases or search for specific materials. There is also a  **Recent Materials** folder where you find the most recently used materials. **Search** a specific material by name (or, for the Material Library product, by UNS number or DIN number, which are listed in the Material Browser when available).

When browsing the material databases, in particular the **Material Library**, some materials include additional information — UNS number, DIN number, and composition.

As in [Figure 9-3](#), the following information is included in the window to the right of the material tree. Navigate in the material tree and click a material to display the information.

	Material availability is based on the type of COMSOL Multiphysics license. For example, if you have the MEMS Module, you have the Built-In , Liquids and Gases , MEMS , and Piezoelectric material libraries.
---	---

PROPERTIES

While browsing the databases, predefined material properties for the selected material are listed in a table in the columns **Property**, **Expression**, **Unit**, and the **Property group** to which the material property belongs. If **Property group** is empty, the material property is a **Basic** property.

Under **Property reference**, for the materials in the Material Library product, reference information about a material's properties appears when you click a property above.

INPUTS

For some materials, predefined function inputs are listed in a table in the columns **Input**, **Variable**, and **Unit**. Inputs appear for material properties defined using functions that require the input. Typical inputs are temperature and pressure, for temperature- and pressure-dependent material properties, respectively.

CREATE A NEW MATERIAL LIBRARY OR IMPORT A MATERIAL LIBRARY

Click the **New Material Library** button () to open the **New Material Library** dialog box. You can also right-click a material and select **Add to New Library** () to create a new material library and add that material to the new library. Go to [Creating a New Material Library](#) and [Adding and Editing Materials](#).

Click the **Import Material Library** button () to open the **Choose Material Library** dialog box. Go to [Importing a Material Library](#).

Material Browser

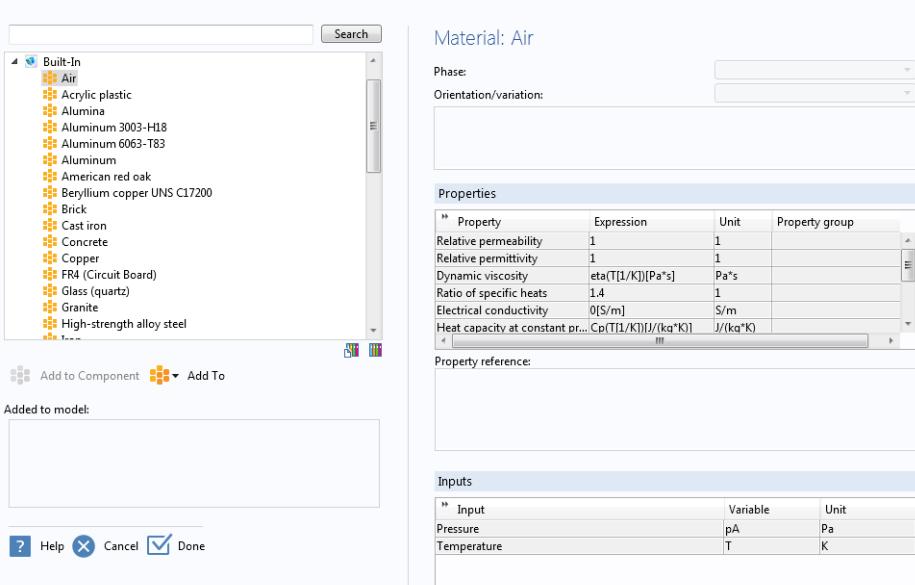

Figure 9-3: The Material Browser details a material's properties after selection. In this example, the properties of Air, selected from the Built-In library, are listed to the right of the Material Browser folders.

The Add Material Window

The **Add Material** window is similar to [The Material Browser Window](#). It has the same material libraries available but does not include the detailed properties about each material. The number of material libraries depends on which COMSOL Multiphysics products your license includes. See [About the Material Databases](#) for information about available material databases. This window is a quick way to add materials to models.

To open the **Add Material** window  :

- From the **Materials** toolbar, click **Add Material**.
- Right-click the **Materials** node () and select **Add Material from Library**.

As in [Figure 9-5](#), you can browse all the available material databases or search for specific materials. There is also a **Recent Materials** folder where you find the most recently used materials. **Search** a specific material by name (or, for the Material Library product, by UNS number or DIN number).

Figure 9-4:

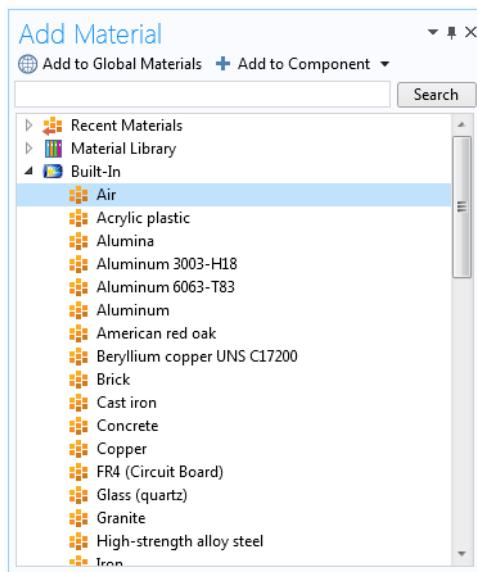

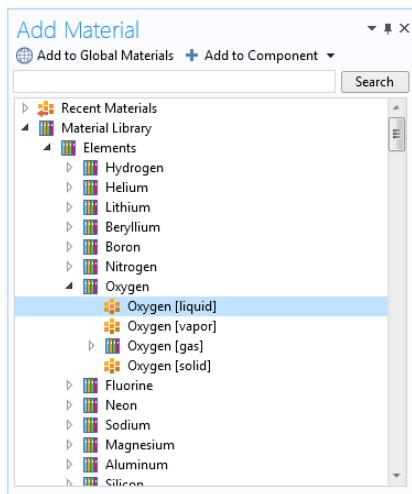

Figure 9-5: The Add Material window. In this example, Air is selected from the Built-In library and can be added to the Material node in the local Component or as a global material in the Model Builder.

ADDING MATERIALS TO A COMPONENT

You can add materials to Component nodes using either the **Add Material** or **Material Browser** windows. In either window, use the **Search** field to find materials by name, UNS number, or DIN number. Or click any of the folders and subfolders to locate and add a specific material. For example, from the left column, click **Built-In** and in the right column, click **Air**. To add a material to the current component, click the **Add to Component** button, right-click the material and choose **Add to Component**, or, in the **Add Material** window, press Enter. In the **Add Material** window you can also add a material to global **Materials** list and to the current selection. In the **Material Browser** window, you can also add the material to the global **Materials** list and to an existing user-defined or new material library.

Using the Add Material Window

- 1 Open the **Add Material** window (see [The Add Material Window](#)).
- 2 In the **Add Material** window, select a material by phase (liquid, vapor, gas, or solid) and orientation/variation, when available.
- 3 Click the **Add to Global Materials** or **Add to Component** buttons, or right-click the material and select the same options from the context menu. If there is more than one **Component** node in the model tree, add the material to the applicable geometry.
 - Click the **Add to Global Materials** button to add it under the global **Materials** node.
 - Click the **Add to Component** button to add the material to the active component in the **Model Builder** and then make it an active material in the domains (or other geometric entities) where it is selected. You can also select any of the components in the model to add it to its **Materials** node, or select **Add to Switch 1**, for example, to add it under a **Switch** node for materials under the global **Materials** node. Right-click the **Material** node to rename it, for example, using the name of the material it represents.

Using the Material Browser Window

- 1 Open the **Material Browser** window (see [The Material Browser Window](#)).
- 2 In the **Material Browser**, select options from the **Phase** and **Orientation/variation** lists, when available (only included for some materials in the Material Library product). In this window you can review the material **Properties** and **Input** sections.
- 3 Click the **Add to Component** button () under the list of materials to add the selected material to the current model component. Alternatively, click the **Add To** button () to add the material to the global **Materials** node (choose **Global Materials**), to any available model component, or to an existing or new user-defined material library. You can also right-click the selected material node to add that material to a model component or user-defined material library. Materials that you have selected to add to any of the model components appear in the **Added to model** list.
- 4 Click **Done** () to add the materials to the model tree in the **Model Builder** and close the **Material Browser**. If it is the first material in that model component, the material in the **Model Builder** becomes the default material; otherwise, the material is initially not used anywhere but becomes the active material in the domains (or other geometric entities) that you pick to add to that material's selection list.

Materials

Use the nodes under **Materials** () to add predefined or user-defined materials, to specify material properties using model inputs, functions, values, and expressions as needed, or to create a custom material library. Also see [Material Link](#), [Switch for Materials](#), [Working with External Materials](#), and [About the Material Databases](#).

You can right-click the **Materials** node and select **Add Materials from Library** to add a material using [The Add Material Window](#) or select **Browse Materials** to open [The Material Browser Window](#) for more thorough information about the available materials in the material libraries. You can also select **Blank Material** to add a **Material** node with no predefined material properties.

MATERIAL OVERVIEW

This section provides an overview of the materials in the Component node and where they are used. You can also add materials under **Global Definitions**. To access such global materials in a model component, use a [Material Link](#).

The **Material** column lists the current materials in the Component using the materials' node labels from the model tree according to the settings defined in [Displaying Node Names, Tags, and Types in the Model Builder](#).

The **Selection** column lists the geometric entities selected for the material (the domains, boundaries, or edges where the material is defined).

ERRORS RELATING TO THE MATERIAL NODES

If a material property in a physics interface takes its value from a material and no material is defined for the same geometric selection, a stop sign () displays in the leftmost column and the **Material** column contains **Entities needing a material**. The **Selection** column contains the geometric entities in which a material definition is missing. The Materials node also indicates when there is a material error (see [Figure 9-6](#)). For example, if some property is deleted but needed in a part of the geometry, then the icon indicates where the error is located.

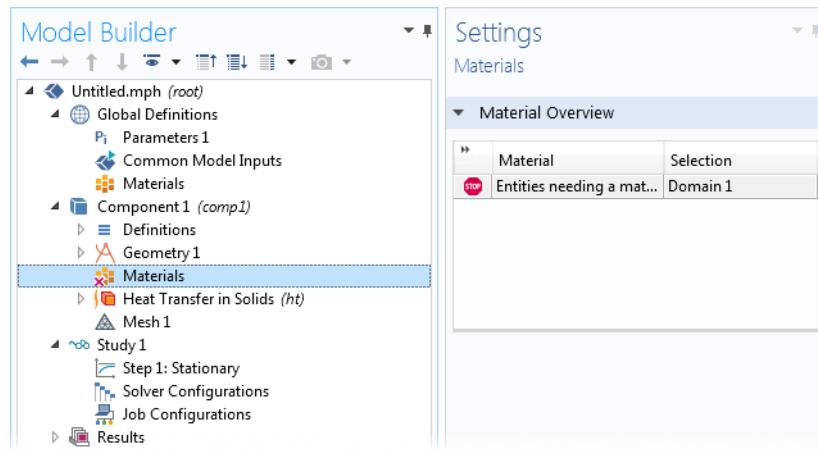

Figure 9-6: An example of a Materials node error.

The Settings Window for Material

The **Settings** window for **Material** () summarizes the predefined or user-defined material properties for a material. This is where you can add or change material properties to fit your model and assign the material to all types of geometric entities: domains (most common), boundaries, edges (3D models only), or points. Also see [Material Link](#) and [Switch for Materials](#).

After adding a material (see [The Add Material Window](#) and [The Material Browser Window](#)), click the Material node (for example, **Material 1** or **Copper**) in the **Model Builder**. The **Settings** window for **Material** opens.

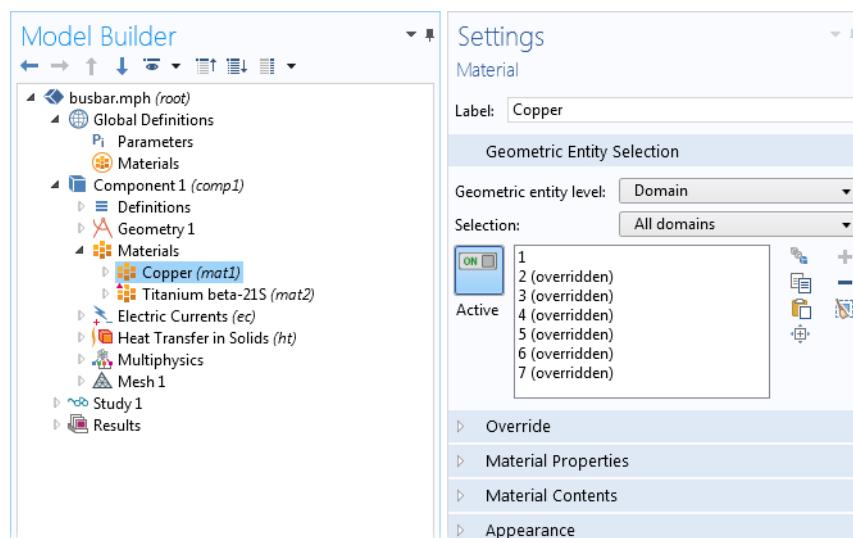

Figure 9-7: Click the Copper node to open the Settings window for Material for the node.

GEOMETRIC ENTITY SELECTION

Assign the material to some or all entities on a specific **Geometric entity level** — **Domain**, **Boundary**, **Edge** (3D only), or **Point** — on the geometry in the **Graphics** window (the geometry in the model).

	By default, the first material in the Component is active in all domains (or all boundaries or edges if the Component only contains surfaces or edges). By assigning other materials to some or all domains, the first material is overridden and remains active only in domains where no other material, added below it in the Materials branch, is active.
	If the Component contains features on different geometric entity levels, such as solid mechanics in domains coupled to beams on edges, and the features use the same material, you need to add two Material nodes with the same material, one defined in the domains, and the other defined on the edges.

OVERRIDE

This section shows if the material, in some or all parts of the geometry where it is active, is overridden by another material added underneath it in the Materials branch, or if it overrides another material above it.

The **Overridden by** list shows the names of the materials that override this material. The **Selection** list in the **Geometric Entity** section displays (**overridden**) for the geometric entities in which this material is overridden.

The **Overrides** list shows the names of the materials that this material overrides.

	<ul style="list-style-type: none">• Physics Exclusive and Contributing Node Types• Physics and Variables Selection• Physics Node Status
---	---

MATERIAL PROPERTIES

You can add material properties to the material if they are not already included. To do so, browse the available material property categories (**Basic Properties**, **Acoustics**, and so on), and select a material property or a collection of material properties in one of the property groups or material models that appear under the main level of material property categories. Right-click the material property or property group and select **Add to Material**, or click the **Add to Material** button (+) to add the material property or group of properties to the material.

	Review the properties listed in the Material Contents table before adding new material properties.
---	---

For example, under **Acoustics>Viscous Model** select **Bulk viscosity (muB)** and right-click to **Add to Material** or click the **Add to Material** button (+). If you add a material model like the **Viscous Model** with more than one property, all of its material properties are added to the **Material Contents** table. In this example, a **Viscous model** node is added to the **Model Builder** and its associated properties are added to the **Material Contents** table.

	To delete a property group, right-click the property group node (in the Model Builder) and select Delete (). The Basic property group cannot be deleted.
---	---

A Note About Adding Basic Material Properties

Material properties can be added to the **Basic** group or to any **User-Defined Property Group** from two locations — the **Settings** windows for **Material** and **Property Group**.

- When material properties are added from the **Basic** node's or a user-defined group node's **Settings** window for **Property Group**, they are listed under **Output Properties** and **Model Inputs** in that **Settings** window.
- When material properties are added from the **Settings** window for **Material**, the available material properties are listed under **Material Properties** and are added to the list under **Material Contents** with the property group listed. The list under **Material Contents** also contains material properties added from a subnode with a **Settings** window for **Property Group**.

Material Type

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Nonsolid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame and for which no unique material reference configuration can be defined.

Simply put, **Solid** materials associate material properties with specific pieces of the material, and the properties follow the material as it moves around. In particular, a solid material may be inherently anisotropic, meaning that its axes rotate together with the material. The **Nonsolid** choice, in contrast, applies typically to liquids and gases whose properties are associated with fixed points in space and insensitive to local rotation of the material. Such materials are inherently isotropic when studied in isolation, but may exhibit anisotropy induced by external fields. In practice, this means that any anisotropic tensor properties in a Non-solid material must be functions of some external vector field.

MATERIAL CONTENTS

This section lists all of the material properties that are defined for the material or required by the physics in the model. The table lists the **Property**, **Variable**, **Value**, and **Unit** for the material property as well as the **Property group** to which the material property belongs. The **Property group** corresponds to the subnodes in the **Model Builder** with the same name. If required, edit the values or expression for the property's **Value**.

The left column provides visual cues about the status of each property:

- A stop sign () indicates that an entry in the **Value** column is required. It means that the material property is required by a physics feature in the model but is undefined. When you enter a value in the **Value** column, the material property is added to its property group.
- A warning sign () indicates that the material property has been added to the material but is still undefined. An entry is only required if the material property is to be used in the model.
- A green check mark () indicates that the property has a **Value** and is currently being used in the physics of the model.
- Properties with no indication in the left column are defined but not currently used by any physics in the model.

You can change the value for any property by editing its value directly in the **Value** column, or, for a selected property, click the **Edit** button () to enter a value in the window that opens. If the property can be anisotropic, you can choose to enter the values in one of these forms: **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic**. The **Variable** column lists the variable names corresponding to the degree of anisotropy. For example, for a symmetric electrical conductivity, it contains **{sigma11, sigma12, sigma22, sigma13, sigma23, sigma33}**; **sigmaj = sigmaji**. For an isotropic electrical conductivity, it contains **sigma_iso**; **sigmaj = sigma_iso**, **sigmaj = 0**, where **sigma_iso** is the name of the variable for the isotropic electrical conductivity (available as, for example, **mat1.def.sigma_iso**).

APPEARANCE

The settings in this section make it possible to control or change the default appearance of a material in the Graphics window when working in the materials or physics parts of the model tree.

In 3D components, the material is rendered including color and texture when **Scene Light** is active. In 2D models and in 3D components, when **Scene Light** is turned off, only a change of color is visible.

The **Family** list provides quick settings approximating the appearance of a number of common materials — **Air**, **Aluminum**, **Brick**, **Concrete**, **Copper**, **Gold**, **Iron**, **Lead**, **Magnesium**, **Plastic**, **Steel**, **Titanium**, and **Water**. Select **Custom** to make further adjustments of the specific settings for colors, texture, reflectance, and so on. The default custom settings are inherited from the material selected last from the **Family** list.

Specular Color, Diffuse Color, and Ambient Color

For each of these properties, click the **Color** button to assign a **Custom** specular color or select a standard color from the list: **Black**, **Blue**, **Cyan**, **Gray**, **Green**, **Magenta**, **Red**, **White**, or **Yellow**.

The combination of **Specular color**, **Diffuse color**, and **Ambient color** gives a 3D object its overall color:

- **Specular color** is the color of the light of a specular reflection (specular reflection is the type of reflection that is characteristic of light reflected from a shiny surface).
- **Diffuse color** represents the true color of an object; it is perceived as the color of the object itself rather than a reflection of the light. The diffuse color gets darker as the surface points away from the light (shading). As with Ambient color, if there is a texture, this is multiplied by the colors in the texture, otherwise it is as if it has a white texture.
- **Ambient color** is the color of all the light that surrounds an object; it is the color seen when an object is in low light. This color is what the object reflects when illuminated by ambient light rather than direct light. Ambient color creates the effect of having light hit the object equally from all directions. As with Diffuse color, if there is a texture, this is multiplied by the colors in the texture; otherwise, it is as if it has a white texture.

For examples of specular, diffuse, and ambient light, which are related to these definitions, see [About the 3D View Light Sources and Attributes](#).

Noise

The **Noise** check box is selected by default, with the default **Normal vector noise scale** and **Normal vector noise frequency** taken from the material. Enter other values as needed, or click to clear the **Noise** check box.

- Noise is a texture that disturbs the normals when calculating lighting on the surface. This causes the surface to look rough and textured.
- Normal vector noise scale is the power of the noise texture. A high value creates a stronger texture of the surface. A value between 0–1 is suitable.
- Normal vector noise frequency is the size of the noise disturbances. A small value creates smaller features on the texture. A value between 0–10 is suitable.

Diffuse and Ambient Color Opacity

The default **Diffuse and ambient color opacity** is 1.

Lighting Model

The default **Lighting model** — **Blinn-Phong** or **Cook-Torrance** — is based on the material. Select **Simple** instead as needed.

The different lighting models provide a set of techniques used to calculate the reflection of light from surfaces to create the appropriate shading. For example, a specular highlight is the bright spot of light that appears on shiny objects when illuminated. Specular highlights are important in 3D computer graphics because they provide a strong visual cue for the shape of an object and its location with respect to light sources in the scene.

For **Blinn-Phong**, the default **Specular exponent** is 64. The specular exponent determines the size of the specular highlight. Typical values for this property range from 1 to 500, with normal objects having values in the range 5 to 20. This model is particularly useful for representing shiny materials.

For **Cook-Torrance**, the default **Reflectance at normal incidence** and **Surface roughness** are taken from the material. The Cook-Torrance lighting model accounts for wavelength and color shifting and is a general model for rough surfaces. It is targeted at metals and plastics, although it can also represent many other materials.

- Reflectance at normal incidence is the amount of incoming light (0–1) from the normal direction (of the surface) that is reflected.
- Surface roughness is a value that describes microreflectance on the surface. Higher values create a rougher look of the surface with fewer highlights. A value from 0–1 is suitable.

Property Groups

The **Settings** window for **Property Group** is where output properties and model inputs are added, local properties are defined, and expressions for material properties are entered in a specific property group such as **Basic**. The property groups are subnodes to a material node. The **Settings** window for **Property Group** is displayed when you click the property group node (for example, **Basic**) under the material node (typically with the material's name — **Aluminum**, for example) in the **Model Builder**.

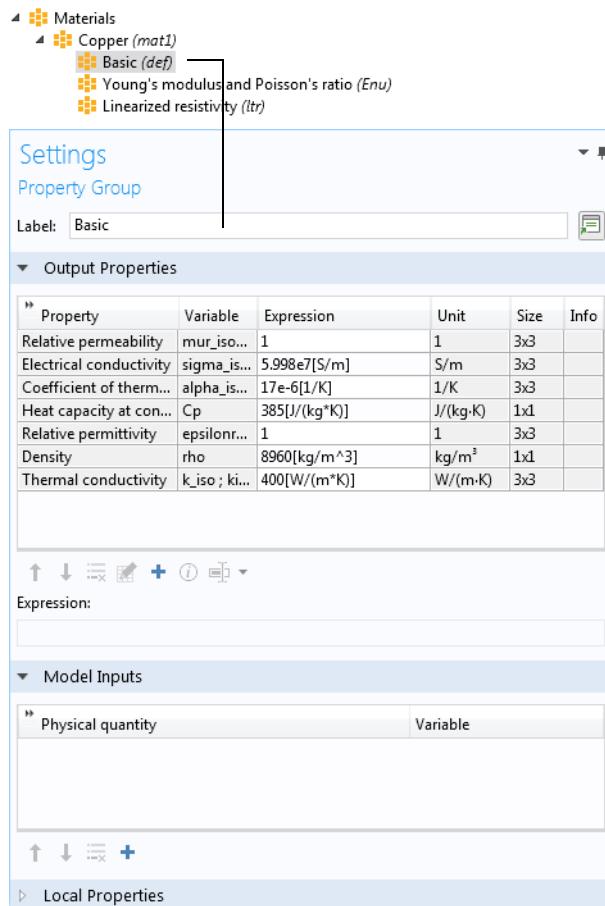

Figure 9-8: An example of a Basic Settings window for Property Group.

A property group under a material creates the following variables:

TABLE 9-1: VARIABLES GENERATED FROM A PROPERTY GROUP

TYPE	VARIABLE NAME	SCOPE	SELECTION	EXAMPLE
Basic property	Variable name of physical quantity	root.material	Material selection	root.material.rho
		root.<comp>. <mat>. <group>	Global selection	root.comp1.mat1.def.rho
Output property	Property name	root.material.group	Material selection	root.material.linzRes.alpha
		root.<comp>. <mat>. <group>	Global selection	root.comp1.mat1.linzRes.alpha

OUTPUT PROPERTIES

The predefined material properties in the property group appear in a table in the **Output Properties** section.

It is only possible to add, move, and delete output properties from the **Basic** material properties and with user-defined property groups.

Click the **Add** button () to add another output property, which you choose from one of the available physical quantities in the **Physical Quantity** dialog box that opens.

If required, edit the expressions in the list's **Expression** column. Edit directly in the table or in the **Expression** field underneath the table. You can insert predefined expressions by clicking the **Insert Expression** button () or clicking Ctrl+Space and then choosing an expression from the list of predefined expressions. You can also click the **Edit** button (), which opens a dialog box for easier specification of orthotropic and anisotropic material properties (tensors), when applicable. Select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** when entering the data in the material property's dialog box. In the **Expression** column, use a syntax with curly braces such as $\{k_{11}, k_{21}, k_{31}, k_{12}, k_{22}, k_{32}, k_{13}, k_{23}, k_{33}\}$ to enter anisotropic material properties for a 3-by-3 tensor k_{ij} in the order $k_{11}, k_{21}, k_{31}, k_{12}, k_{22}, k_{32}, k_{13}, k_{23}$, and k_{33} . 1, 2, and 3 represent the first, second, and third direction in the active coordinate system. In many cases (for example, when entering the elasticity matrix for structural mechanics), the matrix must for physical reasons be symmetric. The upper diagonal part of the matrix you enter will then be mirrored when forming the actual constitutive matrix, and the lower diagonal part is ignored.

The **Variable** column lists the variable names depending on the type of anisotropy. For an isotropic k , k_iso represents its single scalar value.

The **Unit** and **Size** columns provide information about the unit and size of the output property. The size is 1x1 for a scalar value such as density and 3x3 for a tensor (matrix) quantity such as electrical conductivity.

If desired, you can add information about the property, such as references for its value or expression. To do so, click the **Edit/Show Property Information** button () and enter the property information in the dialog box that opens and then click **OK**. When information is available for a property, and information symbol () appears in the **Info** column.

Use the **Move up** (), **Move down** (), and **Delete** () buttons to organize the table as needed.

MODEL INPUTS

The model inputs are physical quantities, such as temperature, that are used as inputs in the expressions that define the output properties (for example, to describe a temperature-dependent physical quantity). For example, adding **Temperature** as a model input with the variable name T makes it possible to use an expression for the heat capacity at constant pressure C_p , such as $300[J/(kg*K)]*T[1/K]$, which works regardless of the name of the actual dependent variable for temperature in the model that uses the temperature-dependent material. Without the model input, the expression above only works with a temperature variable called T .

Click the **Add** button () to add another model input, which you choose from one of the available physical quantities in the **Physical Quantity** dialog box that opens.

Use the **Move up** (), **Move down** (), and **Delete** () buttons to organize the table as needed.

LOCAL PROPERTIES

Here you can enter a user-defined property by entering its variable name in the **Name** column and its corresponding **Expression** and organizing the table as needed. You can also enter a **Description**, which appears in the **Property** column in the **Material Contents** section of the parent **Material** node. In that node, the **Name** entered here appears in the **Variable** column. These local properties are useful for parameterizing functions that describe material properties if they contain inputs other than those that are model inputs (such as temperature and pressure). For

example, a local property can be a reference value at a certain temperature. Use the **Move up** (↑), **Move down** (↓), and **Delete** (☒) buttons to organize the tables as needed.

You can use local properties to parameterize a material (for example, to create a generic “template” material for a particular symmetry class of anisotropic materials). You can then adjust the local property values for each instance of the material.

About Automatic Adding of Property Groups to a Material

Material property groups are automatically added to the material node in the **Model Builder**. You can also add additional predefined property groups or create a **User-Defined Property Group** (on the **Materials** toolbar, click **User-defined Property Group** (☒) or right-click the **Material** node). The available properties are collected in property groups according to the physical context.

Each property group has a **Settings** window for **Property Group**. When a **Model Builder** node is clicked (for example, **Basic**), the **Settings** window for **Property Group** displays specific information about that property group. The physical properties for all property groups are summarized in a **Material Contents** table on the **Settings** window for the parent **Material** node.

Material Link

Add a **Material Link** node (☒) under a **Materials** node in a model component to add a link to a material that you have added under the global **Materials** node (☒) and use it as a material in that component’s geometry. The **Material Link** node’s **Settings** window is similar to the **Settings** window for a material node (see [The Settings Window for Material](#)), with the exception that there is no **Material Properties** sections. Instead, it includes the following section:

LINK SETTINGS

From the **Material** list, select the global material that you want to link to:

- Any global material node, to use that material in the component.
- Any **Switch** node, if you want to run a material sweep.
- **None**, to not link to any global material.

Click the **Go to Material** button (☒) to move to the selected material node. Click the **Add Material from Library** button (✚) to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

Switch for Materials

Use the **Switch** node (☒) to switch between materials during a solver sweep. You add the materials as subnodes under the **Switch** node. Right-click to add a **Blank Material** or select **Add Material from Library** to select materials from the libraries in the **Add Material** window. The switch for materials acts essentially as a switch statement in a programming language; that is, it dynamically selects one of its underlying branches depending on a parameter that can be controlled from the solvers, using a [Material Sweep](#) study.

The **Switch** node’s **Settings** window contains the following sections:

MATERIAL CONTENTS

This section lists all of the material properties that are defined for the material or required by the physics in the model on domains where the **Switch** node is the active domain material. The table lists the **Property**, **Name**, **Value**,

and **Unit** for the material property as well as the **Property group** to which the material property belongs. The **Property group** corresponds to the subnodes in the **Model Builder** with the same name. If required, edit the values or expression for the property's **Value**.

The list includes properties that are defined by any of the materials under the **Switch** node. The left column provides visual cues about the status of each property:

- A stop sign () indicates that some subnode is missing a required **Value**. That is, the material property is required by a physics feature in the model but is not defined for all switch cases.
- A warning sign () indicates that the material property has been added to some material subnode but is still undefined.
- A green check mark () indicates that the property has a **Value** in all subnodes and is currently being used in the physics of the model.

APPEARANCE

The settings in this section make it possible to control or change the default appearance of the material switch in the Graphics window when working in the materials or physics parts of the model tree. See [The Settings Window for Material](#) for more information.

Layered Material

In the **Layered Material** node (), you can specify the properties of a multilayer laminate. It is used when defining the properties of the following features:

- The Layered Shell interface (requires the Composite Materials Module).
- **Layered Linear Elastic Material** in the Shell interface (requires the Composite Materials Module).
- **Thin Layer** in the Heat Transfer in Solids interface.
- The Heat Transfer in Shells interface (requires the Heat Transfer Module).
- The Electric Currents, Layered Shell interface (requires the AC/DC Module).

A **Layered Material** node can be present in two locations in the Model Builder:

- The most common place is under **Global Definitions>Materials**. When you reference a layered material from a physics interface, you do it indirectly through either a [Layered Material Link](#) or a [Layered Material Link \(Subnode\)](#) under **Materials** in the current component.
- It can also be a subnode under a [Layered Material Stack](#) node in a component.

LAYER DEFINITION

In this table you specify the properties of each layer.

Click the **Add** button () to add another table row. Use the **Move up** (), **Move down** (), and **Delete** () buttons to organize the table as needed. To completely reset the table to its default state, you can use the **Reset to Default** button ().

Conceptually, the layers are ordered from bottom to top of the laminate. Enter the following data in the table:

Layer

Here you can assign a name to the layer for future reference. The default is a sequential numbering: Layer 1, Layer 2, and so on.

Material

Select any available material. If the **Layered Material** node is located under **Global Definitions**, the list contains only global materials. If the **Layered Material** node is used as a subnode to a **Layered Material Stack**, also materials defined under **Materials** in the component are available.

When you have a certain row in the table selected, you can access three shortcuts:

- Click the **Blank Material** () button to add a new blank material under global materials. The material is referenced in current row of the **Material** column.
- Click the **Add Material from Library** () button to add a new material under global materials from Material Libraries. The material is referenced in current row of the **Material** column.
- Click the **Go to Material** () button to jump to the definition of the material selected on the current row.

When you add a new row to the table, the same material as on the previous row is selected. This means that if you have many, not adjacent, layers with the same material, it is more efficient to initially add all layers with that same material. Then you can go back and change the material for some layers. Alternatively, you can reorder the layers using the **Move up** () and **Move down** () buttons.

Rotation

If the material in the layer is orthotropic or anisotropic, enter the angle in degrees (positive counterclockwise) from the first principal axis of the laminate to the first principal axis of the layer. Even for an isotropic material, the orientation can matter for result presentation, since it affects the interpretation of for example stress tensor components.

Thickness

Enter the thickness of the layer (default unit: m).

Mesh elements

In the physics interfaces, the layered materials are handled through the concept of a virtual *extra dimension*. For a layered material defined on a boundary, you can think of that as an extra coordinate in the normal direction. Enter the number of elements that you want in the extra dimension for the layer.

INTERFACE PROPERTY

In some physics features, not only the layers themselves but also the interfaces between them are important. In such a case, you can assign materials to the interfaces in this table. The number of interfaces is one more than the number of layers because the free top and bottom surfaces of the laminate are also considered as interfaces.

In most cases, you do not need to enter anything in this section.

Interface

This is the interface name, for future reference. As a default, the interface name is constructed from the names of the two adjacent layers. For the top and bottom interfaces, the labels “up” and “down” are used for the two exterior sides.

You can rename the interfaces. This is, however, seldom needed.

Position

This column shows the location of the interface. The distance is counted from the bottom of the laminate. The column is for information only, and cannot be modified.

Material

Select the material of the interface. You only need to assign materials to the interfaces which are explicitly referenced by physics features.

Figure 9-9 shows an example of the settings for a layered material. The layer names have been entered manually, whereas the interfaces have retained their default names.

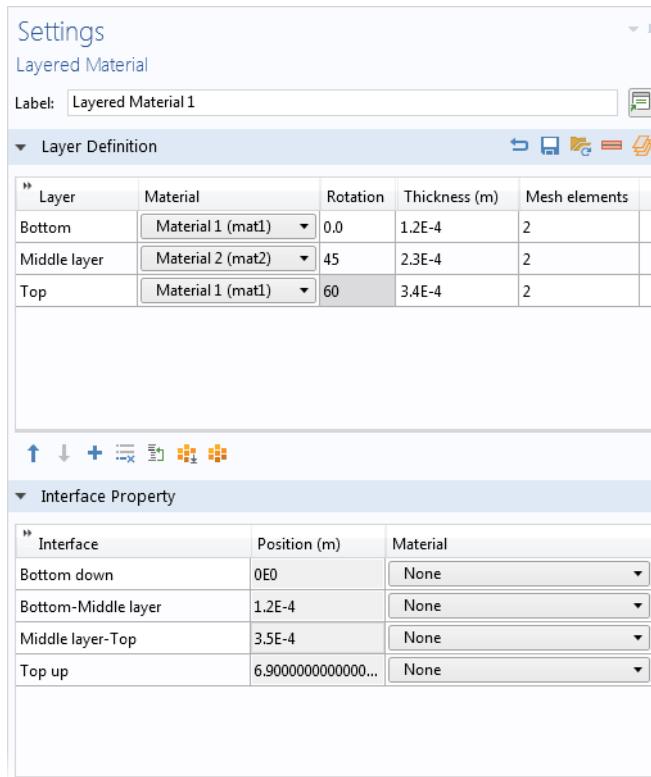

Figure 9-9: Settings for a material with three layers.

You can save the laminate definition to a text file by clicking the **Save Layers to File** () button. For the example above, the text file has the following contents:

```
Bottom mat1 0.0 1.2E-4 2
"Middle layer" mat2 45 2.3E-4 2
Top mat1 60 3.4E-4 2
```

To load a text file on this format, click the **Load Layers from File** () button. For complex laminates, it may be easier to start by creating the text file representation in a text editor, than to enter the data in the GUI.

When loading a file, the second column containing the material tag is ignored. The reason is that there is no way to ascertain that a material tag like 'mat2' would point to the same material in another context. You can even load a file where that column is absent.

You have two options for visualizing the laminate defined in the **Layered Material** node. To see the thickness of each layer, click the **Layer Cross Section Preview** () button. This will give a plot like the one shown in [Figure 9-10](#).

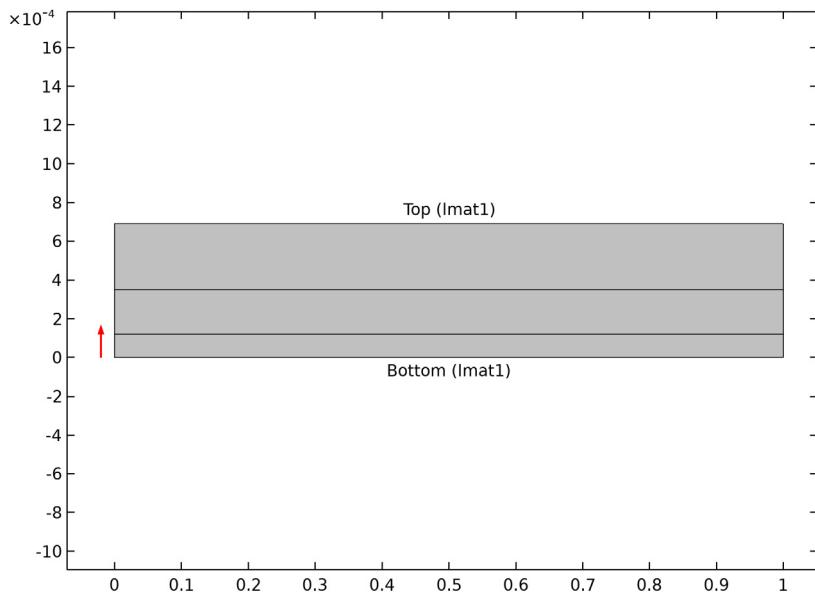

Figure 9-10: The layer cross section plot for a material with three layers.

To visualize the layer orientations, click the **Layer Stack Preview** () button. In [Figure 9-11](#), an example of such a plot is shown. The *x*-axis corresponds to the principal laminate direction, and the stripes indicate the principal direction of each layer.

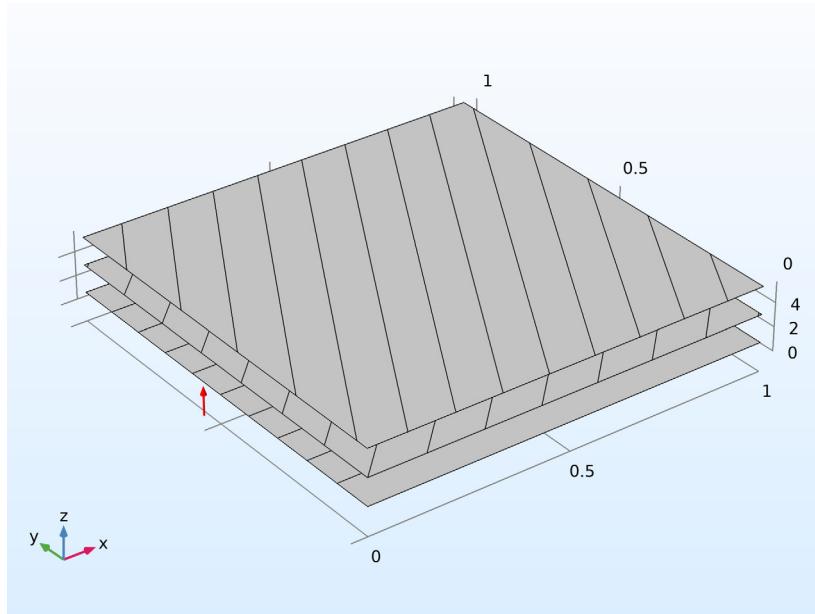

Figure 9-11: The layer stack preview plot for a material with three layers.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plots.

In the **Distance between the orientation lines** text field, you can enter a value for the spacing of the stripes showing the orientation of the principal orientation of the layer. The layer itself is always drawn as a square with the unity side length. If you deselect the corresponding check box, no orientation lines are drawn.

The value of the **Thickness-to-width ratio** is used by both types of preview plots.

- In a layer stack preview plot, it controls the height of the stack in the z -direction. For laminates with many layers, you may need to increase this value.
- In the layer cross section preview plot, it controls the height in the y -direction. The width is always unity.

Clear the **Shows labels in cross section plot** check box to remove the text labels showing layer names and materials.

Layered Material Link

The **Layered Material Link** node () provides a bridge from a **Layered Material**, located under **Global Definitions**, to a physics feature residing in a component. A physics feature designed to work with layered materials cannot directly reference a **Layered Material**. The **Layered Material Link** node is located in the **Layers** submenu under a **Materials** node.

ORIENTATION AND POSITION

Select a **Coordinate system** defining the principal directions of the laminate. The orientation of each layer, given in the **Layered Material** node, is a rotation from the first coordinate axis of this coordinate system. Only **Boundary System** coordinate systems can be selected.

Choose a **Position — Midplane on boundary**, **Down side on boundary**, **Up side on boundary**, or **User defined**. This controls the possible offset of the layered material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Down side on boundary**, and the value -1 corresponds to **Up side on boundary**. Values may be outside the range -1 to 1, in which case the reference surface is outside the laminate.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** () button, you get a preview plot of the layered material, including the location of the reference surface (Figure 9-12). The height of the laminate in the plot is controlled by the value of the **Thickness-to-width ratio** specified in the **Preview Plot Settings** for the selected layered material.

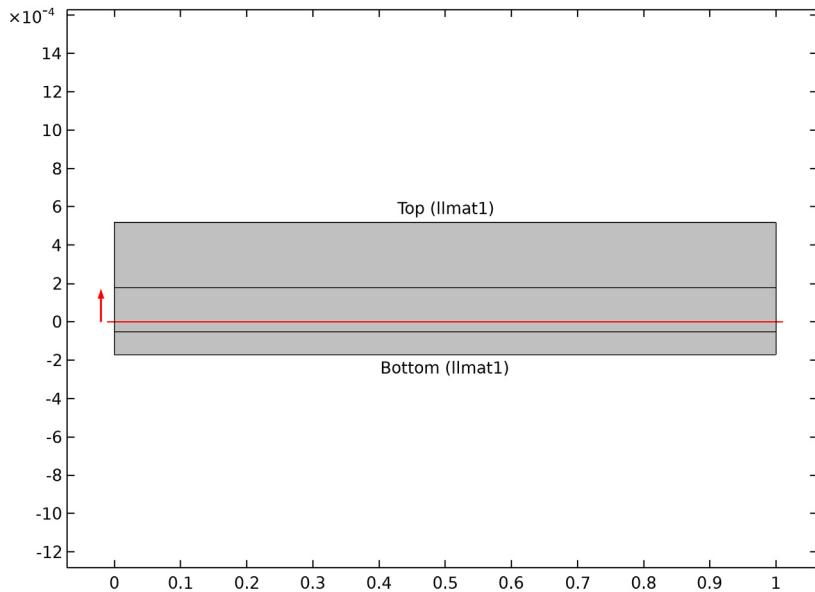

Figure 9-12: Layer cross section preview plot with relative offset set to 0.5.

NONLAYERED MATERIAL SETTING

In some cases, a single standard material definition is needed on the same boundary as a layered material. This can, for example, be the case if two different physics interfaces are active on the same boundary, but only one of them supports a layered material definition. You can select any nonlayered material from the **Material** list. This selection is completely analogous to using a [Material Link](#).

You cannot use an ordinary **Material** or **Material Link** with the same selection as the **Layered Material Link**. These nodes override each other.

By clicking the **Go to Material** () button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button () to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

LAYERED MATERIAL SETTING

Select a layered material from the **Material** list. You can also select a [Switch for Materials](#).

By clicking the **Go to Material** () button, you can jump to the settings for the selected material.

Click the **Add Layered Material** button () to add another **Layered Material** or a **Switch**. The added material then becomes the one selected in the **Material** list.

MATERIAL CONTENTS

See the documentation for [Material Contents](#) for the **Material** node.

The **Value** column will usually contain the string **Layer**, indicating that the actual value is layer dependent.

APPEARANCE

See the documentation for [Appearance](#) for the **Material** node.

Layered Material Stack

In the **Layered Material Stack** node () , you can compose a new layered material by stacking other layered materials on top of each other. There are three main reasons why you may want to do this:

- The layup is repetitive, say with the same four layers repeated five times. Rather than defining twenty layers in a **Layered Material** node, you define four, and then add this definition five times in a **Layered Material Stack**.
- There are layer drop-offs, that is some layers are not present everywhere in the structure. Then, it is efficient to create only subsets of the laminate in **Layered Material** nodes, and use a number of **Layered Material Stack** nodes to combine them into different configurations.
- Two **Layered Material Stack** nodes can have parts of their definitions linked to the same **Layered Material** node. When a transition through a continuity feature is used, the corresponding layers in two laminates defined as stacks can be connected automatically.

The **Layered Material Stack** node is located in the Layers submenu under a Materials node. To compose the stack, you add subnodes to the **Layered Material Stack**. These subnodes can be either a **Layered Material** or a **Layered Material Link (Subnode)**. You can add any number of subnodes, and mix the two types. The order of the subnodes determines the ordering of the layers in the final laminate.

ORIENTATION AND POSITION

Select a **Coordinate system** defining the principal directions of the laminate. The orientation of each layer, given in the **Layered Material** node, is a rotation from the first coordinate axis of this coordinate system. Only **Boundary System** coordinate systems can be selected.

Choose a **Position** — **Midplane on boundary**, **Down side on boundary**, **Up side on boundary**, or **User defined**. This controls the possible offset of the layered material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Down side on boundary**, and the value -1 corresponds to **Up side on boundary**. Values may be outside the range -1 to 1, in which case the reference surface is outside the laminate.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** () button, you get a preview plot of the stacked layered material, including the location of the reference surface. In [Figure 9-13](#), a laminate composed of three stacked layered materials, each consisting of three layers is shown. Note that there is a slight indentation, used for emphasizing the transition from one part of the stack to the next.

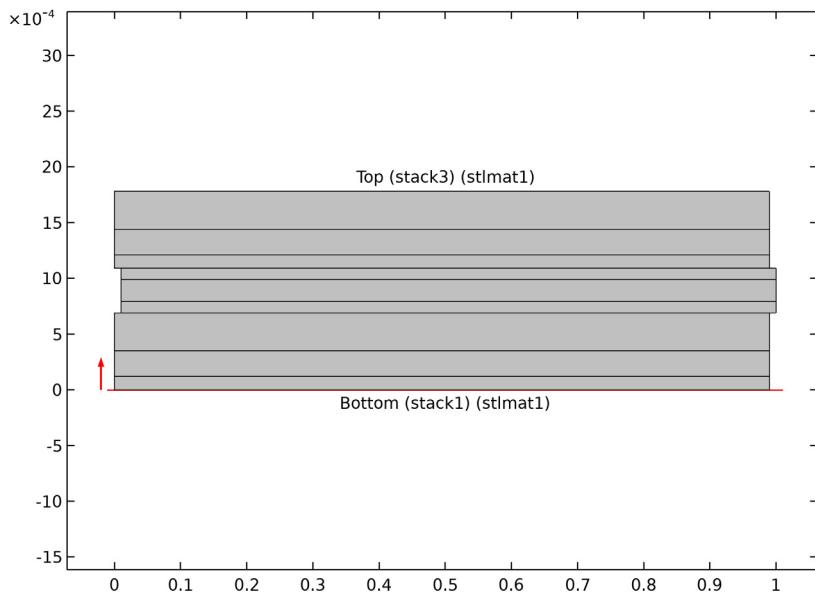

Figure 9-13: Layer cross section preview plot with relative offset set to Down side on boundary.

NONLAYERED MATERIAL SETTING

In some cases, a single standard material definition is needed on the same boundary as a layered material. This can for example be the case if two different physics interfaces are active on the same boundary, but only one of them supports a layered material definition. You can select any non-layered material from the **Material** list. This selection is completely analogous to using a [Material Link](#).

You cannot use an ordinary **Material** or **Material Link** with the same selection as the **Layered Material Stack**. These nodes override each other.

By clicking the **Go to Material** () button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button () to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plot.

The value of the **Thickness-to-width ratio** controls the height in the *y*-direction. The width is always unity.

Deselect the **Shows labels in cross section plot** check box to remove the text labels showing layer names and materials.

MATERIAL CONTENTS

See the documentation for [Material Contents](#) for the **Material** node.

The **Value** column will usually contain the string `Layer`, indicating that the actual value is layer dependent.

APPEARANCE

See the documentation for [Appearance](#) for the **Material** node.

Layered Material Link (Subnode)

The **Layered Material Link** subnode () is used for referencing a **Layered Material** from a **Layered Material Stack** node. You can add any number of **Layered Material Link** subnodes under a **Layered Material Stack** node.

LINK SETTINGS

Select a layered material from the **Material** list.

By clicking the **Go to Material** () button you can jump to the settings for the selected material.

Click the **Add Layered Material** button () to add another **Layered Material** or a **Switch**. The added material then becomes the one selected in the **Material** list.

Single Layer Material

The **Single Layer Material** node () provides a quick way to define data for a non-layered material to be used in physics feature designed for layered materials. Using a single layer material is equivalent to defining a **Layered Material** with only one layer, and then referencing it through a **Layered Material Link**.

LAYER DEFINITION

- Enter a **Label**, which can be used for future reference. The default is **Layer**.
- Enter the layer **Thickness** (default unit: m)
- Enter the **Rotation**. If the material in the layer is orthotropic or anisotropic, enter the angle in degrees (positive counterclockwise) from the first principal axis of the laminate to the first principal axis of the layer. Even for an isotropic material, the orientation can matter for result presentation, since it affects the interpretation of for example stress tensor components.
- Select a **Material** from the list. It contains all global materials, as well as all materials defined in the current component.

By clicking the **Go to Material** () button you can jump to the settings for the selected material.

Click the **Add Material from Library** button () to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

- Enter the number of **Mesh elements**. In the physics interfaces, the layered materials are handled through the concept of a virtual *extra dimension*. For a layered material defined on a boundary, you can think of this as an extra coordinate in the normal direction. Enter the number of elements that you want in the extra dimension for the layer.

INTERFACE PROPERTY

In some physics features, not only the layers themselves but also the interfaces between them are important. In such a case, you can assign materials to the interfaces in this table. The single layer shell has two external interfaces — the downside and the upside — and no internal interfaces. You can specify data for the two sides individually.

In most cases, you do not need to enter anything in this section.

The **Label** is the interface name, for future reference. As a default, the interface names are **Downside** and **Upside**, respectively.

Select the **Material** of each interface.

By clicking the **Go to Material** () button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button () to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

NONLAYERED MATERIAL SETTING

In some cases, a single standard material definition is needed on the same boundary as a layered material. This can for example be the case if two different physics interfaces are active on the same boundary, but only one of them supports a layered material definition. You can select any non-layered material from the **Material** list. This selection is completely analogous to using a [Material Link](#).

You cannot use an ordinary **Material** or **Material Link** with the same selection as the **Single Layered Material**. These nodes override each other.

By clicking the **Go to Material** () button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button () to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

ORIENTATION AND POSITION

Select a **Coordinate system** defining the principal directions of the laminate. The orientation of the single layer, as given in **Rotation**, is a rotation from the first coordinate axis of this coordinate system. Only **Boundary System** coordinate systems can be selected.

Choose a **Position — Midplane on boundary**, **Down side on boundary**, **Up side on boundary**, or **User defined**. This controls the possible offset of the material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Down side on boundary**, and the value -1 corresponds to **Up side on boundary**. Values may be outside the range -1 to 1, in which case the reference surface is outside the laminate.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** () button, you get a preview plot of the single layer material, including the location of the reference surface. This plot looks similar to [Figure 9-12](#), but there is only a single layer.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plot.

The value of the **Thickness-to-width ratio** controls the height in the *y*-direction. The width is always unity.

Deselect the **Shows labels in cross section plot** check box to remove the text labels showing layer names and materials.

MATERIAL CONTENTS

See the documentation for [Material Contents](#) for the **Material** node.

The **Value** column usually contains the string **Layer**, indicating that the actual value is layer dependent.

Material Properties Reference

The material properties for the predefined materials are accessible from most physics interfaces. Using this information, either create a material property group or define a completely new material.

In the **Basic>Property Group** window, you can add **Output Properties** under the **Quantities** subsection. You can also add **Model Inputs** to, for example, create a temperature-dependent material property.

About Model Inputs

Model inputs is a special type of parameter in physics features or physics properties where you can choose from a list of announced variables (typically field quantities such as temperature, concentration, or electric field, where vector fields have three components). Model inputs can also be used as an input to a **Property Group** under a material to represent, for example, a temperature-dependent material property. If the property group specifies that it supports one or more model inputs, any physics feature that uses the group's material will display those model input lists in the **Model Inputs** section of the physics node's **Settings** window. Any physical quantity in COMSOL Multiphysics can be used as a model input.

Model inputs are always available as common model inputs. See [Common Model Inputs](#).

All physical quantities that can act as model inputs declare and define common variables that are always available (for example, `minput.T` for the temperature T).

	To define the absolute pressure for heat transfer, see the settings for the Fluid node. To define the absolute pressure for a Fluid Flow interface, see the settings for the Fluid Properties node (described for the Laminar Flow interface). If you have a license for a Nonisothermal Flow interface, see that documentation for further information.
---	--

Model Inputs and Multiphysics Couplings

About the Output Material Properties

	Some of these material groups are only used by physics interfaces in the add-on modules and detailed information is in the applicable documentation.
---	--

This section describes all available property groups and the material properties that they contain. These material properties can be added to models from two **Settings** windows: the **Material** window and its subnodes' **Property Group** windows.

The Basic group contains over 25 basic properties for use with all materials.

Materials

BASIC MATERIAL PROPERTIES

These common material properties belong to the **Basic** property group.

- When this information is accessed from the **Basic>Property Group** window, it is listed under **Quantities>Output Properties** and **Variable** is listed in the table.
- When this information is accessed from the **Material** window, it is listed under **Material Properties>Basic Properties** and **Name** is listed in the table under **Material Contents**.

TABLE 9-2: BASIC MATERIAL PROPERTIES

PROPERTY	NAME/VARIABLE	SI UNIT
Absorption Coefficient	kappaR	l/m
Activation Energy	dE	J/mol
Bulk Viscosity	muB	Pa·s
Characteristic Acoustic Impedance	Z	Pa·s/m
Coefficient of Hygroscopic Swelling	beta_h_iso, beta_hii	m ³ /kg
Coefficient of Thermal Expansion	alpha	l/K
Compressibility of Fluid	chif	l/Pa
Density	rho	kg/m ³
Diffusion Coefficient	D	m ² /s
Dynamic Viscosity	mu	Pa·s
Electrical Conductivity	sigma	S/m
Electron Mobility	mue	m ² /(Vs)
Extinction Coefficient	betaR	l/m
Frequency Factor	A	l/s
Heat Capacity at Constant Pressure	Cp	J/(kg·K)
Isotropic Structural Loss Factor	eta_s	l
Mass Flux	Mf	kg/(m ² ·s)
Mean Molar Mass	Mn	kg/mol
Permeability	kappa	m ²
Poisson's Ratio	nu	l
Porosity	epsilon	l
Ratio of Specific Heats	gamma	l
Relative Permeability	mur	1
Relative Permittivity	epsilonor	1
Resistivity	res	Ω·m
Scattering Coefficient	sigmaS	l/m
Seebeck Coefficient	S	V/K
Shifted Magnetic Field	shiftedH	A/m
Speed of Sound	cp	m/s
Storage	S	l/Pa

TABLE 9-2: BASIC MATERIAL PROPERTIES

PROPERTY	NAME/VARIABLE	SI UNIT
Surface Emissivity	epsilon_rad	1
Thermal Conductivity	k	W/(m·K)
Thermal Conductivity Supplement	b	1
Vapor Permeability	delta_p	s
Vapor Resistance Factor	mu_vrf	1
Water Content	w_c	kg/m ³
Young's Modulus	E	Pa

The coefficient of thermal expansion (CTE) and the resistivity temperature coefficient have the SI unit 1/K. COMSOL Multiphysics translates this into the Fahrenheit temperature unit using an offset. This translation means that you do not get the expected results.

Use caution when a model uses the coefficient of thermal expansion or the resistivity temperature coefficient and the unit system's temperature is not kelvin.

The rest of the material properties are grouped by application area:

Acoustics Material Properties

Under Acoustics, you find the following acoustic material models with their associated material properties: a **Poroacoustics Model**, a **Thermoviscous Acoustics Model**, and a **Viscous Model**.

These material property groups (including their associated physical properties) can be added to models from the **Material** window. These property groups require the Acoustics Module.

TABLE 9-3: ACOUSTICS MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
POROACOUSTICS MODEL		
Flow resistivity	Rf	Pa·s/m ²
Thermal characteristic length	Lth	m
Viscous characteristic length	Lv	m
Tortuosity factor	tau	1
THERMOVISCOS ACOUSTICS MODEL		

TABLE 9-3: ACOUSTICS MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
Bulk viscosity	μ_B	Pa·s
Density	ρ	kg/m ³
Dynamic viscosity	μ	Pa·s
Heat capacity at constant pressure	C_p	J/(kg·K)
Thermal conductivity	k	W/(m·K)
VISCOS MODEL		
Bulk viscosity	μ_B	Pa·s

Electrochemistry Material Properties

These material property groups for electrochemistry (including their associated physical properties) can be added to models from the **Material** window. These property groups require the Batteries & Fuel Cells Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module.

TABLE 9-4: ELECTROCHEMISTRY MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
EQUILIBRIUM POTENTIAL		
Equilibrium potential	E_{eq}	V
Reference concentration	$c_{E_{eq}ref}$	mol/m ³
Temperature derivative of equilibrium potential	dE_{eq}/dT	V/K
ELECTROLYTE CONDUCTIVITY		
Electrolyte conductivity	σ_{salt}	S/m
ELECTROLYTE SALT CONCENTRATION		
Electrolyte salt concentration	$c_{E_{salt}}$	mol/m ³
LINEARIZED RESISTIVITY		
Reference resistivity	ρ_0	Ω·m
Reference temperature	T_{ref}	K
Resistivity temperature coefficient	α	1/K
OPERATIONAL ELECTRODE STATE-OF-CHARGE		
Maximum electrode state-of-charge	soc_{max}	I
Minimum electrode state-of-charge	soc_{min}	I
SPECIES PROPERTIES		
Transport number	$transNum$	I

Electromagnetic Models

These material property groups for various electromagnetic material models (including their associated physical properties) can be added to models from the **Material** window. These properties require the AC/DC Module, RF Module, or Wave Optics Module.

TABLE 9-5: ELECTROMAGNETIC MODELS MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
BH CURVE	This material node is only available with the AC/DC Module.	
Local Properties	normH	-
Magnetic flux density norm	normB	T
DIELECTRIC LOSSES		
Dielectric loss factor	eta_epsilon	-
Relative permittivity (imaginary part)	epsilonBis	1
Relative permittivity (real part)	epsilonPrim	1
E-J CHARACTERISTIC	This material node is only available with the AC/DC Module.	
Electric field norm	normE	V7M
Local Properties	normJ	-
EFFECTIVE BH CURVE	This material node is only available with the AC/DC Module.	
Local Properties	normHeff	-
Magnetic flux density norm	normBeff	T

Magnetic field norm	normHeff	A/m
HB CURVE	This material node is only available with the AC/DC Module.	
Local Properties	normB	-
Magnetic field norm	normH	A/m
JILES-ATHERTON MODEL PARAMETERS	This material node is only available with the AC/DC Module.	
Maximum magnetization parameter	MsJA (3x3 matrix)	A/m
Langevin slope parameter	aJA (3x3 matrix)	A/m
Pinning parameter	kJA (3x3 matrix)	A/m
Reversibility parameter	cJA (3x3 matrix)	I
Interdomain coupling parameter	alphaJA (3x3 matrix)	I
LINEARIZED RESISTIVITY	This material node defines the electric resistivity (and conductivity) as a linear function of temperature.	
Reference resistivity	rho0	$\Omega \cdot m$
Reference temperature	Tref	K
Resistivity temperature coefficient	alpha	I/K
LOSS TANGENT, LOSS ANGLE	This material node assumes zero conductivity.	

TABLE 9-5: ELECTROMAGNETIC MODELS MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
Loss tangent, loss angle	delta	rad
Relative permittivity (real part)	epsilonPrim	I
LOSS TANGENT, DISSIPATION FACTOR	This material node assumes zero conductivity.	
Loss tangent, dissipation factor	tanDelta	I
Relative permittivity (real part)	epsilonPrim	I
MAGNETIC LOSSES		
Relative permeability (imaginary part)	murBis	-
Relative permeability (real part)	murPrim	-
MAGNETOSTRICTIVE		
Saturation magnetization	Ms	A/m
Initial magnetic susceptibility	chi	I
Saturation magnetostriction	lambdaDas	I
Magnetostriction constants	lambda100	I
Magnetostriction constants	lambda111	I
REFRACTIVE INDEX	This material node assumes a relative permeability of unity and zero conductivity. This material node is only available with the RF Module or the Wave Optics Module.	
Refractive index, imaginary part	ki	-
Refractive index	n	I
STRAIN-MAGNETIZATION FORM	This material node is only available with the AC/DC Module.	
Compliance matrix	sH (6x6 matrix)	I/Pa
Loss factor for compliance matrix sH	eta_sH (6x6 matrix)	I
Piezomagnetic coupling matrix	dHT (3x6 matrix)	m/A
Relative permeability	murT (3x3 matrix)	I
STRESS-MAGNETIZATION FORM	This material node is only available with the AC/DC Module.	
Elasticity matrix	cH (6x6 matrix)	Pa
Loss factor for elasticity matrix cH	eta_cH (6x6 matrix)	I
Piezomagnetic coupling matrix	eHS (3x6 matrix)	T
Relative permeability	murS (3x3 matrix)	I

Equilibrium Discharge

These material property groups for all the material models in the Equilibrium Discharge (including their associated physical properties) can be added to models from the **Material** window. These property groups require the Plasma Module.

TABLE 9-6: EQUILIBRIUM DISCHARGE MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
RADIATION HEAT TRANSFER		
Total volumetric emission coefficient	Qrad	W/m ³

Gas Models

This material property group for an ideal gas (including its associated physical properties) can be added to models from the **Material** page.

TABLE 9-7: GAS MODELS MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
IDEAL GAS		
Heat capacity at constant pressure	Cp	J/(kg·K)
Mean molar mass	Mn	kg/mol
Ratio of specific heats	gamma	I
Specific gas constant	Rs	J/(kg·K)

Piezoelectric Models

These material property groups for piezoelectric materials (including their associated physical properties) can be added to models from the **Material** window. These property groups require the Acoustics Module, MEMS Module, or Structural Mechanics Module.

TABLE 9-8: PIEZOELECTRIC MATERIALS

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
STRAIN-CHARGE FORM		
Compliance matrix	sE	I/Pa
Coupling matrix	dET	C/N
Loss factor for compliance matrix	sE	I
Loss factor for coupling matrix	d	I
Loss factor for electrical permittivity	εT	I
Relative permittivity	epsilonnrT	I
STRESS-CHARGE FORM		
Coupling matrix	eES	C/m ²
Elasticity matrix	cE	Pa
Loss factor for elasticity matrix	cE	I
Loss factor for coupling matrix	e	I
Loss factor for electrical permittivity	εS	I
Relative permittivity	epsilonnrS	I

Piezoresistive Models

These material property groups for piezoresistive materials (including their associated physical properties) can be added to models from the **Material** window. These property groups require the MEMS Module.

TABLE 9-9: GAS MODELS MATERIALS

Piezoresistive coupling matrix	Pil	A/m ²

Semiconductors Material Properties

These material property groups for all the material models in semiconductors (including their associated physical properties) can be added to models from the **Material** window. These property groups require the Semiconductor Module.

The Property Group, Variable Names, and SI Unit columns are applicable to all materials in the Semiconductor Module. However, the Values and References columns listed in [Table 9-10](#) are specifically for Silicon.

Solid Mechanics Material Properties

These material property groups for material models in solid mechanics (including their associated physical properties) can be added to models from the **Material** window. Most of these properties require the Structural Mechanics Module. The property groups of the external material are of a special type that depends on the selected interface type and are not individually documented.

Thermal Expansion Material Properties

This material property group for thermal expansion properties can be added to models from the **Material** page.

TABLE 9-15: THERMAL EXPANSION MATERIAL PROPERTIES

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
IDEAL GAS		
Isotropic tangent coefficient of thermal expansion	alphatanlso	/K
Isotropic thermal strain	dLiso	
Tangent coefficient of thermal expansion	alphatan_iso; alphatanij	/K
Thermal strain	dLi_iso, dLij	

External Material Properties

The property groups of the external materials are of a special type that depends on the selected interface type and are not individually documented. You can incorporate as many parameters in the call to the external DLL when you add an external material, these parameters will appear in the Material node as material inputs, see [Working with External Materials](#) for more information.

User-Defined Materials and Libraries

User-defined materials provide the flexibility needed to design your models and experiments using a combination of existing material properties and properties you define yourself. You can also create your own material database (library) to include materials you use often.

You can also modify and extend existing materials that you load from any of the material libraries. When added to the Component node, the material is a copy of the properties and the material from the library, and you can modify that material's properties in the same way as a user-defined material.

Materials Toolbar

Importing a Material Library

Material libraries are stored as COMSOL Multiphysics model files (.mph file) or as XML files. Any COMSOL model containing materials can be imported as a material library, and conversely a material library stored in the COMSOL Multiphysics model format can be opened and modified in the same way as any other COMSOL Multiphysics model file. The XML format, in contrast, is a simplified text format that can be modified in a text editor or written by some external source of material data.

- 1 In the **Materials** toolbar, click **Browse Material**
- 2 In the **Material Browser** window's toolbar, click the **Import Material Library** () button. The **Choose Material Library** dialog box opens.
- 3 Navigate to a material library file on your computer. To the right of **File name**, choose **XML File (.xml)**, to find material libraries stored as XML files.
- 4 When you have located the file to import, click **Open**.

An example of an external material library is MatWeb. MatWeb provides a service where you can export technical datasheets from MatWeb's collection in the format for a COMSOL material library. For more information about this service, visit www.matweb.com.

Creating a New Material Library and Adding and Editing Materials

When you first open the **Material Browser**, an empty **User-Defined Library** is available for you to start creating your own library of materials (see [Figure 9-1](#)). These steps describe how to create a copy of the existing library, rename it, and then add materials to the empty library.

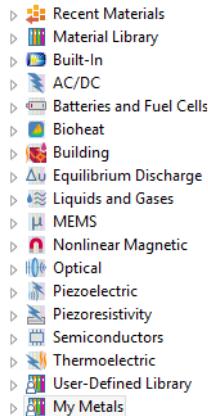

CREATING A USER-DEFINED MATERIAL LIBRARY

- 1 In the **Materials** toolbar, click **Browse Material** .
- 2 Create the empty material library. There are different ways to do this in the **Material Browser** window:
 - Click the **New Material Library** button () under the tree.
 - Navigate to the material you want to add — copper, for example. Right-click and select **Add to New Library**.

- 3 In the **New Material Library** dialog box, navigate to the folder on the computer where the empty **User-Defined Library** database is located. The location of the file varies based on your installation. For example, if the installation is on your hard drive:

 - The file path on Windows might be similar to `C:\Users\Your_Name\.comsol\v54\materials`.
 - On Linux, the file path is typically `~/.comsol/v54/material`.
 - On macOS, it is typically `<home folder>/Library/Preferences/COMSOL/v54/material` (if missing, click the Finder's **Go** menu and hold down the Option key to show the **Library** folder). You can also search for the filename `User Defined Library.mph`.
- 4 Right-click the `User Defined Library.mph` and select **Copy**. Right-click in the window and select **Paste**.
- 5 Click the copied filename to rename it. The new name must include underscores (`_`) between words (for example, `My_Metals.mph`.)
- 6 Click the new material library filename and then click **Save**. The empty database, with a new name, is added to the **Material Browser**.

7 Click **Done** .

ADDING A PREDEFINED MATERIAL TO THE USER-DEFINED MATERIAL LIBRARY

Add any predefined material to a **Component** node in the **Model Builder**. There are different ways to add the material to the Model Builder as well as to the Material Library.

Using the Material Browser

- I To open the **Material Browser**, right-click the **Materials** node and select **Browse Material** , or in the **Materials** toolbar, click **Browse Material** .

- 2 Right-click the material to add, **Copper** for example, and select **Add to My Metals** (or any other material library available).

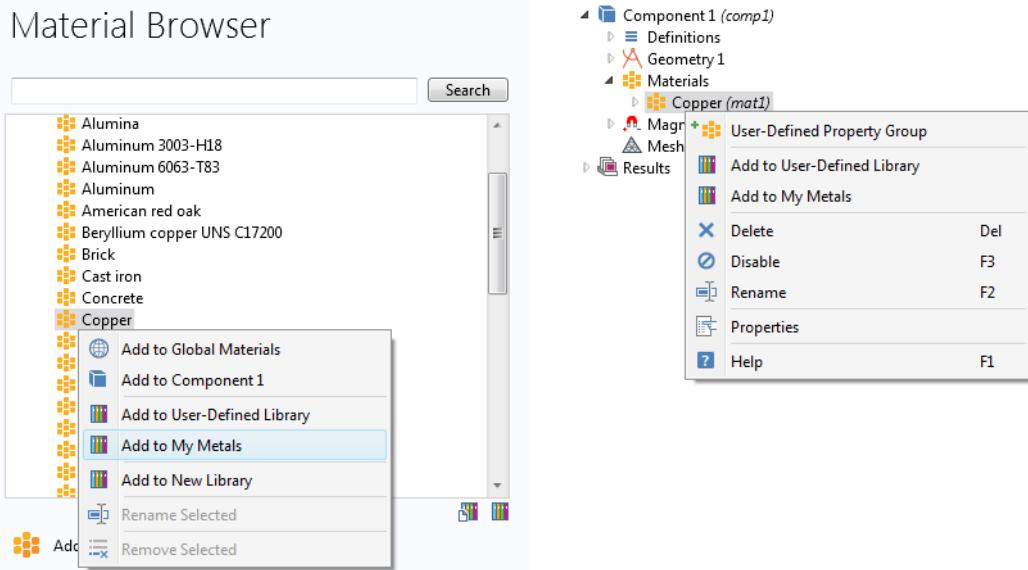

Figure 9-14: Adding a predefined material to a new user-defined library using the Material Browser (left) and after adding a material to the Model Builder (right).

You can also duplicate a material node to start with the defined material properties for that material and then modify some of them to match some similar material that you want to add.

Using the Add Material Window

- 1 In the **Home** or **Materials** toolbar, click **Add Material** to open the **Add Material** window.
- 2 Locate the material you want to add, **Copper** for example, and click **Add to Component**.
- 3 In the **Materials** toolbar, from the **Add to Library** menu, select **Add to <material library name>**. Or in the **Model Builder**, right-click **Copper** and chose an option. See [Figure 9-14](#).

Adding a Blank Material to a Material Library

- 1 In the **Materials** toolbar, click **Blank Material** . An empty **Material** node is added under **Materials** in the **Model Builder**.
- 2 Add material properties to it as desired to define a new material for the user-defined material library.
- 3 In the **Materials** toolbar, from the **Add to Library** menu, select **Add to <material library name>**. Or in the **Model Builder**, right-click **Material** and chose an option. See [Figure 9-14](#).
- 4 Right-click the **Material** node to **Rename Selected** material to a more meaningful name.

EDITING MATERIALS IN A USER-DEFINED MATERIAL LIBRARY

To edit materials in a user-defined material library, open it in the COMSOL Desktop as any other MPH-file. The MPH-file for a user-defined material library contains its materials only (under **Global Definitions>Materials**). You can then edit and modify any aspect of the material in that user-defined library, such as the values of some material properties. When you are done, save the MPH-file for the user-defined material library (under the same name and in the same location). Then restart the COMSOL Desktop to load the updated materials from the user-defined material library.

REMOVING A USER-DEFINED MATERIAL FROM A MATERIAL LIBRARY

In the **Materials** toolbar, click **Browse Material**  to open the **Material Browser**. Locate the material to remove. Right-click the material and select **Remove Selected** ().

Restoring a Deleted User-Defined Library

If the **User-Defined Library** node is deleted in error from the **Material Browser**, you can restore it by following the steps in [Creating a New Material Library and Adding and Editing Materials](#) and then add the file to the Material Browser.

Using Functions in Materials

Functions are useful for describing material properties as, for example, functions of temperature or pressure.

Adding a Function to the Material

Material functions are either automatically added to the **Model Builder** sequence (usually with materials from the material library) or functions can be added based on individual requirements.

- 1 Add a material to the **Component** node (see [The Material Browser Window](#) and [The Add Material Window](#)).
- 2 Add an **Analytic** (), **Interpolation** () or **Piecewise** () function.

	To add an Analytic ( , Interpolation () or Piecewise () function: <ul style="list-style-type: none">• On the Materials toolbar, click Analytic, Interpolation, or Piecewise.• Right-click a property group node (for example, Basic) and select a function from the Functions list.
	To add an Analytic ( , Interpolation () or Piecewise () function: <ul style="list-style-type: none">• Right-click a property group node, for example, Basic and select a function from the Functions list.• On the Materials contextual toolbar, click Analytic, Interpolation, or Piecewise.
	<ul style="list-style-type: none">- Select Analytic to add an analytic function of one or more input arguments.- Select Interpolation to add an interpolation function that can interpolate from structured data (defined on a grid) or unstructured data (defined on a generic point cloud).- Select Piecewise to add a piecewise function that is useful if a material property has different definitions on different intervals. The intervals must not overlap, and there cannot be any holes between intervals.
	<ul style="list-style-type: none">• Defining an Analytic Function• Analytic, Interpolation, and Piecewise
	Once a function is created, you can use it for any property in the same property group.

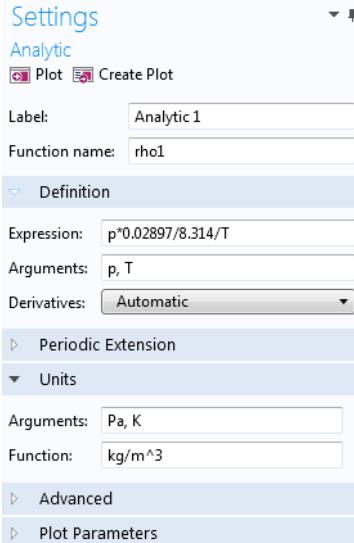

Defining an Analytic Function

Assume that you want to define the density ρ_1 for a material as a function of pressure and temperature: $\rho_1 = \rho_1(p, T)$. You can name the function `rho1(p, T)` and use the expression `p*0.02897/8.314/T` to define the function.

- I On the **Materials** toolbar, click the **Browse Materials** , **Add Material** , or **Blank Material**  button to add a new material to the Component (or use an existing material where density is not defined, or redefine the current expression for the density).

- 2 Add a **Density** property to the material.
 - a In the **Model Builder**, click the **Material** node.
 - b In the **Settings** window for **Material**, click to expand the **Material Properties** section. Under **Basic Properties**, right-click **Density** and **Add to Material**.

A **Density** property is added to the **Basic** property group.
- 3 In the **Model Builder**, under the material node, right-click **Basic** and select **Functions>Analytic**. This adds an **Analytic** subnode () under **Basic**.
- 4 On the **Settings** window for **Analytic**, enter **rho1** in **Function name**. Replace the default name.
- 5 Under the **Definition** section:
 - a In the **Expression** field, enter $p*0.02897/8.314/T$.
 - b In the **Arguments** column, enter p, T .
- 6 Under **Units**:
 - a In the **Arguments** field, enter Pa, K as the units for the pressure and the temperature, respectively.
 - b In the **Function** field, enter kg/m^3 as the unit for the function's output (density). The function **rho1** can now be used to define the density in your material.

- 7 Click the **Material** node. In the **Settings** window for **Material**, under **Material Contents**, enter $\text{rho1}(p, T)$ in the **Value** column (in the **Density** row).

Material Contents				
#	Property	Name	Value	Unit
	Density	rho	$\text{rho1}(p, T)$	kg/m^3

Click the **Basic** node to notice that the **Density** analytic function is defined in the **Settings** window for **Property Group** under **Output Properties**. The expression will be orange if there are no variables p and T for pressure and temperature, respectively, defined in the component. See [Figure 9-15](#).

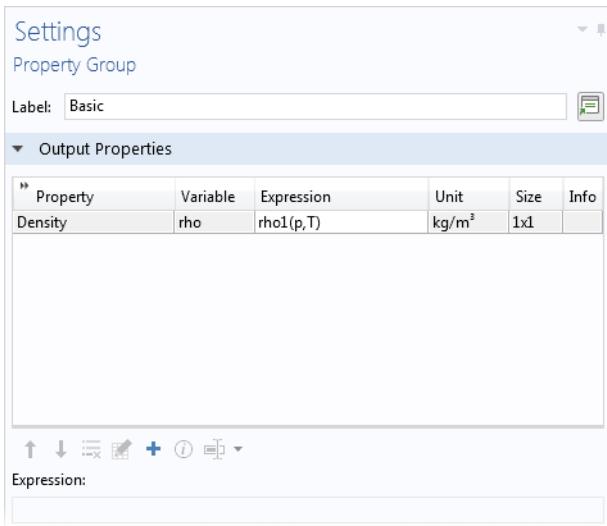

Figure 9-15: A density property is defined using an analytic function.

Working with External Materials

The External Material Model

A general external material model defines a relationship between a number of *input quantities* and a number of *output quantities*, a relationship that may also depend on *model parameters* and stored *states*. From the physics interfaces' point of view, an external material model is a black box, which may implement any relationship between provided input and required output quantities.

The external material model is implemented as a function with a C calling convention, compiled and linked to create a dynamically linked library that can be called from a material feature in COMSOL Multiphysics at runtime. In each solver iteration, current values of the input quantities and model parameters are passed together with previous values of model states as arguments to the external function. The external function is, in return, expected to write new values of model outputs, their partial derivatives with respect to model inputs, as well as updated state values to other preallocated function arguments.

The following sections provide an overview of the external materials framework, as well as details on the built-in interface types and instruction for compiling and linking a shared library.

As a security precaution, running code contained in external libraries is by default not allowed in a new COMSOL installation. Therefore, in order to use external material models, you must open the **Preferences** dialog box, go to the **Security** page, and select **Allow external libraries**.

Using External Materials in Physics Interfaces

In order for a physics interface to make use of external materials, it must contain one or more features that provide input quantity definitions and make use of returned output quantities in equations and postprocessing expressions. Such features are currently available in the Solid Mechanics; Magnetic Fields; and Magnetic Fields, No Currents interfaces.

- Using external materials in Solid Mechanics requires a Structural Mechanics Module or MEMS Module license.
- AC/DC interfaces supporting external materials are only available with an AC/DC Module license, except for Magnetic Fields in 2D.

EXTERNAL MATERIAL INTERFACE TYPES

Given that a physics feature requires certain output quantities and defines certain input quantities, there are many possible ways to set up a call to an external function, including declarations of material properties and states. The required interface specification, or *interface type*, is contained in an *external material socket*, which does a number of different things:

- It defines the call syntax for the external material functions; that is, it defines the function name, return type, and the number of arguments with their data types and sizes.
- It defines a mapping between input and output quantity tensor components in the COMSOL Multiphysics variable namespace and positions in external function arguments.
- It defines a mapping between function argument positions and partial derivatives of outputs with respect to inputs.

- It decides which input quantities should be evaluated at the last converged step — rather than at the last iteration — and sets up states for these variables.
- It declares material model state variables and maps them to positions in the function arguments.
- It declares required material properties and maps them to the function arguments.
- It specifies error handling procedures, including error messages for various exit conditions.

The call syntax is in general not fixed for a given socket. Most sockets allow socket parameters to control certain aspects of the socket behavior, including:

- Whether to pass arguments as real or complex numbers.
- Whether to call an initialization function in the external library before the solver is started.
- Whether to call a cleanup function in the external library.
- What user-defined state array names to declare and pass to the external function, as well as the size of each array.
- Whether to add a preallocated string argument of a chosen size to the argument list, to which a detailed error message can be written if the external material function fails in some way.
- Whether to add a number of string arguments at the end of the argument list.

For an external shared library to be compatible with COMSOL Multiphysics, it must follow the conventions specified by some socket. Conversely, when using an existing external library in a multiphysics model, it is important to choose the right **Interface type** and parameters. Failure to do so will result in the external library being called with unexpected arguments, leading to arbitrary behavior.

It is not necessary for a socket to define all output quantities required by a physics feature. The socket and external library may compute only some quantities, while others are left to be specified by property groups under the External Material feature. For example, the built-in General stress-strain relation socket only returns second Piola-Kirchhoff stress as output, while the physics features using this interface type also may require the material density. The density may instead be specified as an expression in the Basic property group.

It is also possible to set the **Interface type** to **None** to select no socket and instead set up the relation between input and output quantities as expressions directly in an external material feature. This behavior is intended mostly for testing and debugging of multiphysics models.

Sockets and associated material property groups are identified by an ID tag that must be unique among all COMSOL installations between which files will be shared. In order to avoid conflicts between built-in sockets and future user-developed sockets, a full Java-style naming convention has been adopted. Therefore, for example, the built-in General H(B) relation socket has the unique ID `com.comsol.generalHBRrelation` and the associated material property group has tag and name `comcomsolgeneralHBRrelation` — that is, a direct concatenation of the ID.

SOLVER ITERATIONS AND STATE UPDATES

This section describes quantities as being evaluated either at the *current* step or at the *previous converged* step. This is related to the iteration pattern of the solvers. The external material functionality is primarily intended for modeling materials with some kind of memory or path dependence (for example, inelastic solid materials or materials exhibiting electromagnetic hysteresis). This means that simulations must be performed in steps over an interval of time or some parameter (which can often be interpreted as a pseudo-time).

Whether a time-dependent or parametric solver is used, taking a step forward requires solving a nonlinear problem, which is typically an iterative procedure. In order for the convergence to be efficient, the modified Newton solver

used needs correct Jacobian information (the Jacobian is sometimes called the *tangential stiffness matrix*), which must be provided by the external material functions in the form of partial derivatives of output argument components with respect to input argument components. When the nonlinear iteration converges, the solution for that time step or parameter step is stored, and the solver moves on to the next step.

The external material functions are typically called in each iteration in the inner nonlinear loop. Arguments that are evaluated at the *current* step are reevaluated at each inner iteration, while arguments defined at the previous converged step retain the value they had when the previous nonlinear iteration converged; that is, the value that was last stored. State variable arguments are passed to the external material function with the same previous converged values in each inner nonlinear iteration. The external material function is expected to overwrite this previous value with a new value corresponding to the current iteration, but this value will only be stored and the states updated when the inner nonlinear iteration converges.

RESULT PRESENTATION

The external material function may also be called during result presentation. In COMSOL Multiphysics, the stored solution consists of the degrees of freedom plus any possible state variables.

As an example, if you have coded your own elastoplastic material model for solid mechanics, you will typically store the plastic strains as states. If you then during result presentation make a plot of the stresses, the material function is called in order to compute the stresses from the displacements and plastic strains. This will happen at a large number of locations in the mesh.

The states are stored at the integration points, so if you request integration point results of the right order, there will be a call to the external material with a consistent already converged state. If the function is well coded, it will then return the stress state after a single iteration.

Often the material function is however called from a location not being an integration point, for example a mesh node. In this case, the values of the state variables are taken from the closest integration point, while the total strains are computed from the displacement field gradients at the evaluation location. This combination does in general not provide a converged state, so iterations will be needed inside the material function in order to find the stress state. This can have several negative effects:

- The iterations will make the evaluation more expensive.
- The accuracy is decreased, since the state variable values are taken from a neighboring location.
- In the worst case, evaluation in the material function fails completely. What happens in this case depends on how you handle exceptions.

For these reasons it is advantageous, both from a performance and an accuracy point of view, to evaluate results only at the appropriate integration points. In order to ensure that, you can add the `gpeval` operator to your expressions. Instead of plotting for example `solid.mises`, use an expression like `gpeval(4,solid.mises)`.

Built-in Material Function Interface Types

There are currently six different built-in external material function interface types, or *sockets*, which have many traits in common:

- General stress-strain relation
- General stress-deformation relation
- Inelastic residual strain
- Inelastic residual deformation
- General H(B) relation
- General B(H) relation

These built-in material function interfaces expect the external library to contain at least an evaluation function called `eval`, with a signature following the following pattern:

```
int eval(...,           // Interface-type-specific arguments
         int *nPar,      // Number of material model parameters, input
         double *par,     // Material model parameters, input
         int *nStates1,   // Size of first state array, input, optional
         double *states1, // First state array, input/output, optional
         int *nStates2,   // Size of second state array, input, optional
         double *states2, // Second state array, input/output, optional
         char *errMsg,    // Error message, output, optional
         char *arg1, char *arg2, ...) // Extra string arguments, optional
```

The user is required to specify an array of material model parameters, called `par`. The number of parameters `nPar` is specified implicitly as the length of the material property array, which must be defined as a property in a property group under the calling **External Material** feature or set in the **Material Contents** table in the **External Material** node's settings. The material property expression list specified in the this way is interpreted as a list of model expressions which are evaluated at the points for which external material outputs are requested.

The user may also specify a list of state arrays to be defined at each integration point, as well as the length of each array. The array lengths and values are passed to the external function in consecutive pairs of arguments, here formally called `nStates1`, `states1`, `nStates2`, `states2`, etc. Note that the state arrays are both input and output: when the function is called, they contain the previous step converged values of the states; on return, they must contain the state values to be stored if the solver decides to proceed to the next step.

The optional `errMsg` argument allows returning a detailed error message if the evaluation must be terminated abnormally. It is a preallocated string of specified size.

The property group which stores the `par` array may also specify another array of *extra function library string arguments*, `arg`, which are passed unevaluated as separate string arguments to the external material function. Note that the number of string arguments passed in this way is not checked.

Initialization and Cleanup

In addition to the `eval` function, the external library may contain functions called `init` and `cleanup`. The initialization function has the following signature:

```
int init(int *nPar,           // Number of material model parameters
         int *nStateArgs,     // Number of user-defined state vectors
         int *stateArgsSize,  // User-defined state vector sizes
         int *errMsgSize,    // Size of error message output argument
         int *nStringArgs,   // Number of string array arguments
         char *errMsg,        // Error message argument, output, optional
         char *arg1, char *arg2, ...) // Extra string arguments, optional
```

The first five arguments are always passed. The remaining may or may not be present, depending on settings in the **External Material** node from which the external library is called. If `errMsg` is not present, the `errMsgSize` argument will be negative. The number of extra `char*` arguments at the end of the argument list is given by the `nStringArgs` argument.

The initialization function is called every time a new native representation of the Multiphysics problem is created. In a solver sequence, this point corresponds to the **Compile Equations** node. But native representations may also be

created at other times, for example when showing a default solver. You can rely on the `init` method being called at least once before the solver is started, but it may be called multiple times.

The arguments passed to the `init` method describe the way that the `eval` function will subsequently be called. Implementing the `init` method to check that argument numbers and sizes agree with the implementation in the `eval` function is good practice, and can prevent unexpected program termination caused by reading outside the arguments actually passed.

The `cleanup` function is called when the native representation is discarded. This typically happens when a solution object is overwritten or otherwise discarded, at the latest at program exit. The function has the following signature:

```
int cleanup(char *errMsg,           // Error message argument, output, optional
            char *arg1, char *arg2, ...) // Extra string arguments, optional
```

The arguments passed are the same as the last arguments to the `init` function, with the same sizes and values.

Note that the `cleanup` function is called immediately if the `init` function terminates with an error. It must therefore be written in such a way that it is tolerant against missing arguments.

Error Handling

The functions must return an integer values. For the `eval` function, the following return values are defined:

TABLE 9-16: ACCEPTED RETURN VALUES FOR THE INIT FUNCTION

RETURN VALUE	MEANING
0	Normal exit
1	Error: "Wrong number of parameters"
2	Error: "Wrong number of states"
anything else	Unspecified error

For the `init` function, the following return values are defined:

TABLE 9-17: ACCEPTED RETURN VALUES FOR THE INIT FUNCTION

RETURN VALUE	MEANING
0	Normal exit
1	Error: "Wrong number of parameters"
2	Error: "Wrong number of states"
3	Error: "Wrong number of arguments"
4	Error: "Insufficient error message storage"
anything else	Unspecified error

For the `cleanup` function, any nonzero return value is reported as "External material cleanup error".

When the return value signals an error, it is also possible to supply an error details string in the optional output argument, `errMsg`. The error message argument, if present, is a preallocated string of a specified size.

GENERAL STRESS-STRAIN RELATION

The **General stress-strain relation** socket implements a stress-strain relation computing a second Piola-Kirchhoff stress tensor given the current Green-Lagrange strain together with a material property vector and a vector of stored states. The expected external material function signature is:

```
int eval(double *el,           // Green-Lagrange strain, input
        double *S1,           // Second Piola-Kirchhoff stress, output
```

```

double *Jac,           // Jacobian of stress with respect to strain, output
int *nPar,             // Number of material model parameters, input
double *par,            // Material model parameters, input
int *nStates1,          // Size of first state array, input, optional
double *states1,         // First state array, input/output, optional
int *nStates2,          // Size of second state array, input, optional
double *states2, ...    // Second state array, input/output, optional
char *errMsg,           // Error message argument, output, optional
char *arg1, char *arg2, ... // Extra string arguments, optional

```

The **e** and **s** tensors are given in Voigt order; that is., the components in **e** are $\{e_{xx}, e_{yy}, e_{zz}, e_{yz}, e_{xz}, e_{xy}\}$ and similarly for **s**. The Jacobian **Jac** is a 6-by-6 matrix of partial derivatives of components of **s** (rows) with respect to components of **e** (columns); the matrix is stored in row-major order. All components refer to the local material coordinate system. Note that **Jac** in general is non-symmetric since the three last components of **e** represent strain tensor components, rather than engineering shear ($\gamma_{ij}=2e_{ij}$). For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

GENERAL STRESS-DEFORMATION RELATION

The **General stress-deformation relation** socket implements a stress-deformation relation computing a second Piola-Kirchhoff stress tensor given the current and previous deformation gradient, the current and previous local temperature, the local material coordinate system, a material property vector, plus standard optional arguments. The expected external material function signature is:

```

int eval(double *F1Old,           // Deformation gradient at previous step, input
        double *F1,                 // Deformation gradient at current step, input
        double *tempOld,            // Temperature at previous step, input
        double *temp,               // Temperature at current step, input
        double *sysT,               // Local material coordinate system, input
        double *delta,              // Time step / Continuation parameter increment
        double *S1,                 // Second Piola-Kirchhoff stress, output
        double *Jac,                // Jacobian of stress with respect to deformation
                                  // gradient, output
        int *nPar,                 // Number of material model parameters, input
        double *par,                // Material model parameters, input
        int *nStates1,              // Size of first state array, input, optional
        double *states1,             // First state array, input/output, optional
        int *nStates2,              // Size of second state array, input, optional
        double *states2, ...        // Second state array, input/output, optional
        char *errMsg,               // Error message argument, output, optional
        char *arg1, char *arg2, ...) // Extra string arguments, optional

```

The **F1Old** and **F1** tensors are given as 3-by-3 matrices expanded in row-major order, where the row index refers to global (displacement) directions, and the column index refers to directions in the local material coordinate system. The coordinate system itself, **sysT**, is passed as a 1-by-9 concatenation of the local system's three covariant base vectors expressed in global material coordinates. The argument **delta** is a scalar reserved for future use.

The output stress tensor, **S1**, is given in Voigt order; that is, the components in **S1** are $\{S1_{xx}, S1_{yy}, S1_{zz}, S1_{yz}, S1_{xz}, S1_{xy}\}$, where the indices refer to the local material coordinate system. The Jacobian **Jac** is a 6-by-9 matrix of partial derivatives of components of **S1** (rows) with respect to components of **F1** (columns); the matrix is stored in row-major order. For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

INELASTIC RESIDUAL STRAIN

The **Inelastic Residual Strain** socket implements an update procedure for an additive inelastic contribution to the total Green-Lagrange strain. Total stress and strain at the previous converged step, current total strain, current temperature, a reference temperature, a material property vector, and a vector of stored states are passed as inputs.

```

int eval(double *sOld,           // Second Piola-Kirchhoff stress at previous step, input
        double *eOld,             // Green-Lagrange strain at previous step, input
        double *e,                 // Green-Lagrange strain at current step, input

```

```

double *T,           // Temperature, input
double *Tref,        // Strain reference temperature, input
double *eInel,       // Inelastic Green-Lagrange strain state, input/output
double *Jac,         // Jacobian of inelastic strain, output
int *nPar,          // Number of material model parameters, input
double *par,         // Material model parameters, input
int *nStates1,       // Size of first state array, input, optional
double *states1,     // First state array, input/output, optional
int *nStates2,       // Size of second state array, input, optional
double *states2, ... // Second state array, input/output, optional
char *errMsg,        // Error message argument, output, optional
char *arg1, char *arg2, ...) // Extra string arguments, optional

```

The `s0ld`, `e0ld`, `e`, and `eInel` tensors are given in Voigt order (that is, the components in `e` are $\{e_{xx}, e_{yy}, e_{zz}, e_{yz}, e_{xz}, e_{xy}\}$) and similarly for the other tensors. The Jacobian `Jac` is a 6-by-6 matrix of partial derivatives of components of `eInel` (rows) with respect to components of `e` (columns); the matrix is stored in row-major order. Note that the primary output quantity `eInel` is declared as states, meaning that the argument on entry contains the previous converged step values. The temperature arguments `T` and `Tref` are standard model inputs, which are specified in the physics feature calling the external material where the Inelastic residual strain socket is selected. For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

INELASTIC RESIDUAL DEFORMATION

The **Inelastic Residual Deformation** socket implements an update procedure for a inelastic contribution to the deformation gradient. Total stress and deformation at the previous converged step, current total deformation, current temperature, a reference temperature, plus standard optional arguments are passed as inputs.

```

int eval(double *s0ld,           // Second Piola-Kirchhoff stress at previous step, input
        double *F10ld,        // Deformation gradient at previous step, input
        double *F1,           // Deformation gradient at current step, input
        double *T,            // Temperature, input
        double *Tref,          // Strain reference temperature, input
        double *F1Inel,        // Inelastic Green-Lagrange strain state, input/output
        double *Jac,           // Jacobian of inelastic strain, output
        int *nPar,            // Number of material model parameters, input
        double *par,           // Material model parameters, input
        int *nStates1,         // Size of first state array, input, optional
        double *states1,       // First state array, input/output, optional
        int *nStates2,         // Size of second state array, input, optional
        double *states2, ...) // Second state array, input/output, optional
        char *errMsg,          // Error message argument, output, optional
        char *arg1, char *arg2, ...) // Extra string arguments, optional

```

The `s0ld`, tensor is given in Voigt order (that is, the components in `s` are $\{s_{xx}, s_{yy}, s_{zz}, s_{yz}, s_{xz}, s_{xy}\}$). The deformation gradient arguments `F10ld`, `F1`, and `F1Inel` are passed as 3-by-3 matrices expanded in row-major order, where the row index refers to global (displacement) directions, and the column index refers to directions in the local material coordinate system. The Jacobian `Jac` is a 9-by-9 matrix of partial derivatives of components of `F1Inel` (rows) with respect to components of `F1` (columns); the matrix is stored in row-major order. Note that the primary output quantity `F1Inel` is declared as states, meaning that the argument on entry contains the previous converged step values. The temperature arguments `T` and `Tref` are standard model inputs, which are specified in the physics feature calling the external material where the Inelastic residual strain socket is selected. For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

GENERAL H(B) RELATION

The **General H(B) relation** socket implements a generalization of an HB curve. It computes an updated magnetic field corresponding to an updated magnetic flux density, given the magnetic field and magnetic flux density at the previous converged step. A material property vector and a vector of stored states are passed as additional input.

Typical implementations will use extra states to model hysteresis.

```

int eval(double *oldB,           // Magnetic flux density at previous step, input
        double *B,             // Magnetic flux density, input
        double *H,             // Magnetic field state, input/output
        double *Jac,            // Jacobian of H with respect to B, output
        int *nPar,              // Number of material model parameters, input
        double *par,             // Material model parameters, input
        int *nStates1,           // Size of first state array, input, optional
        double *states1,          // First state array, input/output, optional
        int *nStates2,           // Size of second state array, input, optional
        double *states2, ...     // Second state array, input/output, optional
        char *errMsg,             // Error message argument, output, optional
        char *arg1, char *arg2, ...) // Extra string arguments, optional

```

The magnetic flux densities `oldB` and `B` and the magnetic field `H` are passed as arrays of length 3. The Jacobian `Jac` is a 3-by-3 matrix of partial derivatives of components of `H` (rows) with respect to components of `B` (columns); the matrix is stored in row-major order. Note that the primary output quantity `H` is declared as states, meaning that the argument on entry contains the previous converged step values. For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

GENERAL B(H) RELATION

The **General B(H) relation** socket implements a generalization of a BH curve. It computes an updated magnetic flux density corresponding to an updated magnetic field, given the magnetic field and magnetic flux density at the previous converged step. A material property vector and a vector of stored states are passed as additional input. Typical implementations will use extra states to model hysteresis.

```

int eval(double *oldH,           // Magnetic field at previous step, input
        double *H,             // Magnetic field, input
        double *B,             // Magnetic flux density state, input/output
        double *Jac,            // Jacobian of B with respect to H, output
        int *nPar,              // Number of material model parameters, input
        double *par,             // Material model parameters, input
        int *nStates1,           // Size of first state array, input, optional
        double *states1,          // First state array, input/output, optional
        int *nStates2,           // Size of second state array, input, optional
        double *states2, ...     // Second state array, input/output, optional
        char *errMsg,             // Error message argument, output, optional
        char *arg1, char *arg2, ...) // Extra string arguments, optional

```

The magnetic fields `oldH` and `H` and the magnetic flux density `B` are passed as arrays of length 3. The Jacobian `Jac` is 3-by-3 matrix of partial derivatives of components of `B` (rows) with respect to components of `H` (columns); the matrix is stored in row-major order. Note that the primary output quantity `B` is declared as states, meaning that the argument on entry contains the previous converged step values. For an explanation of remaining arguments, see [Built-in Material Function Interface Types](#).

For examples showing how to implement and use external materials, see

- <http://www.comsol.com/model/external-material-examples-structural-mechanics-32331>
 - <http://www.comsol.com/model/external-materials-general-hb-bh-relation-32321>
-

Library of Utility Functions for Solid Mechanics

When modeling materials for solid mechanics, there are many common operations that you often need, such as

- Computing principal stresses and other eigenvalues

- Matrix inversion
- Converting tensors between matrix and vector representation

A large library of such utility functions which you can call from your external material function is available.

- For a complete list of utility functions and how they are used, see [Using External Materials](#) in the *Structural Mechanics User's Guide*.
- For instructions how to include utility functions in your external material library file, see [Linking with Utility Functions](#).

How to Compile and Link an External Material Model

To export functions from the DLL when using Microsoft Visual Studio to compile your library, you must declare the functions as `__declspec(dllexport)`. Therefore, to write a source code that works across platforms, use the following `#define` pattern:

```
#ifdef _MSC_VER
#define EXPORT __declspec(dllexport)
#else
#define EXPORT
#endif

EXPORT <return_type> eval(<arguments>) { }
```

COMPILING AND LINKING

To compile the function into a library, place it in a file (here called `ext.c` as an example) and proceed as follows depending on the platform:

See <http://www.comsol.com/system-requirements> for information about supported compiler versions.

- 64-bit Windows with Microsoft Visual Studio 2017:
 - Start **Visual Studio 2017>Visual Studio Tools>VC>x64 Native Tools Command Prompt for VS 2017** from the Windows Start menu.
 - `cd` to the directory that contains `ext.c`.
 - `cl /MT /c ext.c`
 - `link /OUT:ext.dll /DLL ext.obj`
- 64-bit Linux with Intel Compiler:
 - `cd` to the directory that contains `ext.c`.
 - `icc -fPIC -c ext.c`
 - `icc -shared -fPIC -o ext.so ext.o -ldl`
- 64-bit macOS with Intel Compiler:
 - `cd` to the directory that contains `ext.c`.
 - `icc -fPIC -c ext.c`
 - `icc -dynamiclib -fPIC -o ext.dylib ext.o`

For other compilers, refer to the compiler's documentation for instructions on how to compile and create a shared library.

LINKING WITH UTILITY FUNCTIONS

To use the provided utility functions in your external material function, you need to reference a header file that contains the utility function declarations. Add the following line to your file (again, called `ext.c` as an example):

```
#include "csextutils.h"
```

Proceed as follows, depending on the platform:

- 64-bit Windows with Microsoft Visual Studio 2017:
 - Start **Visual Studio 2017>Visual Studio Tools>VC>x64 Native Tools Command Prompt for VS 2017** from the Windows Start menu.
 - `cd` to the directory that contains `ext.c`.
 - `cl /MT /c ext.c /I C:\Program Files\COMSOL\COMSOL54\Multiphysics\data\extmat`
 - `link /OUT:ext.dll /DLL ext.obj C:\Program Files\COMSOL\COMSOL54\Multiphysics\data\extmat\win64\csextutils.lib`
- 64-bit Linux with Intel Compiler:
 - `cd` to the directory that contains `ext.c`.
 - `icc -fPIC -c -I/usr/local/comsol54/multiphysics/data/extmat ext.c`
 - `icc -shared -fPIC -o ext.so ext.o -L/usr/local/comsol54/multiphysics/lib/glnxa64 -lcsextutils`
- 64-bit macOS with Intel Compiler:
 - `cd` to the directory that contains `ext.c`.
 - `icc -fPIC -c -I/Applications/COMSOL54/Multiphysics/data/extmat ext.c`
 - `icc -dynamiclib -fPIC -o ext.dylib ext.o -L/Applications/COMSOL54/Multiphysics/lib/maci64 -lcsextutils`

For other compilers, refer to the compiler's documentation for instructions on how to compile and create a shared library.

Known Issues for External Materials

The external materials framework, being a rather recent addition to COMSOL Multiphysics, suffers from a few known issues that may affect usability in some cases:

- There is no unit support: Inputs are passed to the external function in the model's base unit system and outputs are interpreted in the same system.
- Shared libraries containing external material functions are under some circumstances loaded the first time they are used and then never reloaded. To avoid having to repeatedly restart COMSOL Multiphysics while developing an external material function, you can simply change the name of the linked library each time you make a change to it.
- The way the external functions are called is not fault tolerant in any way. This means that reading or writing outside allocated memory in an external function will typically make the COMSOL Desktop crash. Exercise caution when coding, and always save your COMSOL model before running it with an external material.

External Material

The **External Material** node () sets up an interface between a physics feature and functions in an external shared library. In addition, it contains most of the functionality of a standard **Material** node, letting you add arbitrary

material properties and property groups. Some aspects of a material can be handled by an external library, while others are defined internally in property groups.

The **External Material** node is only available under the **Global Definitions>Materials** node, not under **Materials** inside components. To use property groups under an **External Material** as domain material on geometric entities in a component, use a **Material Link** node.

This section focuses on using a material model from an existing external library in your COMSOL Multiphysics model. General information about the external materials framework and how to create your own custom library can be found under [Working with External Materials](#).

To add an external material to a user-defined material library, right-click the **External Material** node and choose **Add to User-Defined Library** ().

The **Settings** window for the **External Materials** node contains the following sections:

LIBRARY FOR WINDOWS, 64-BIT

Use this section to define a library for the Windows® operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a DLL (native dynamic library) file.

LIBRARY FOR LINUX, 64-BIT

Use this section to define a library for the Linux® operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a .so (native dynamic library) file.

LIBRARY FOR MACOS, 64-BIT

Use this section to define a library for the macOS operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a .dylib (native dynamic library) file.

All libraries must be for a 64-bit architecture.

EXTERNAL MATERIAL MODEL

If the external material DLL is not thread safe, clear the **Thread safe** check box. If the DLL is thread safe, several threads can make calls to the DLL at the same time. By clearing the **Thread safe** check box, you prevent the DLL from being used by more than one thread at the same time.

Select the appropriate **Interface type** matching your library. The default is **None**; other options may vary between COMSOL installations. The following types are preinstalled:

- **General stress-strain relation**
- **General stress-deformation relation**
- **Inelastic residual strain**
- **Inelastic residual deformation**
- **General H(B) relation**
- **General B(H) relation**

If the chosen external library contains initialization and cleanup functions and the interface type allows it, select **Call init()** and **Call cleanup()** as appropriate.

If allowed for the chosen interface type and external library, select the **Pass arguments as complex** check box to use **complex** rather than **double** as the base type in all numeric array arguments to the external functions.

If required by the chosen interface type, specify a **State base name** for each state array that must be stored at each evaluation point and provide a corresponding array size under **Number of states**. Actual state variables are created by adding the `<matname>.state.` namespace as a prefix and appending a state index to the given base names. For example, if for a material with name `extmat1` you request a state array of length 2 with **State base name** `p`, the state values can be accessed during and after a solution as `extmat1.state.p1` and `extmat1.state.p2`.

If the external library's functions are implemented so as to return error details, select **Return error details** and specify a **Maximum error message length**. A preallocated string of the specified length will then be passed as output argument to all functions.

The **Required input quantities**, **Output quantities**, and **Model states** tables provide an overview of the interface, including which quantities are passed to and from calling physics features, which states are declared, and which component variables are defined by the material feature. Note that all variables are defined in the material's namespace. To directly access, for example, the first axial component of a second Piola-Kirchhoff stress output outside the scope of an **External Material** node with the name `extmat1`, use the variable name `extmat1.output.S11`.

Components of the **Required input quantities** are normally defined by a physics feature calling the external material. When using an external material in equation-based modeling, you can set the inputs up manually by defining the required input components (in the material's namespace) as global variables. For example, if external material `extmat1` requires the temperature T as input, define a global variable called `extmat1.input.T`.

Use the **Init** column in the **Model states** table to specify initial values for all internal states used by the external function. This includes both specific states required by the chosen **Interface type** and numbered states added by this feature.

MATERIAL PROPERTIES

The **Material Properties** section of an external material is identical to the same section in a common **Material** feature. See [The Settings Window for Material](#) for more information.

MATERIAL CONTENTS

The **Material Contents** section of an external material is very similar to the same section in a common **Material** feature (see [The Settings Window for Material](#) for more information). The only real difference is that the table shows not only defined output properties and properties required by some physics feature, but also parameters required as input to the external material functions. Depending on the selected **Interface type**, these may appear either as individually named parameters or as a single generic, arbitrary-length parameter array. In the latter case, any particular external library typically requires a specific set of properties in a certain order to be specified as an array inside curly brackets. For example, two required parameters can be specified as `{2e11,0.33}`

The table also shows a row for **Extra library function string arguments**, whose value is expected to be an array of single-quoted strings. These strings are stored in a property group in the same way as other parameters. They are passed to the external library's functions as separate string arguments.

Parameters and string arguments required as input to the external library functions are stored in a property group subnode with the same name as the selected **Interface type**.

APPEARANCE

The **Appearance** section of an external material is identical to the same section in a common **Material** feature. See [The Settings Window for Material](#) for more information.

Module-Specific Material Databases

- See [About the Material Databases](#) for an overview of the material databases and the modules in which they are included.
- For more information about customizing the material's appearance in the Graphics window, see [The Settings Window for Material](#).

AC/DC Materials Database

The electromagnetic material properties that can be stored in this material database, available in the AC/DC Module, are:

- Electrical conductivity and resistivity
- Relative permittivity
- Relative permeability
- Nonlinear BH curves
- Refractive index

The database contains electromagnetic and other material properties for these materials:

MATERIALS

Copper

Soft Iron (without losses)

Soft Iron (with losses)

Quartz

Graphite

Graphite felt

Silicon Carbide

MATERIALS

Jiles-Atherton Isotropic Hysteretic Material

Demagnetizable Nonlinear Permanent Magnet

Some properties depend on the magnetic flux density, location, or temperature. The database contains, depending on the material and in addition to the more common material properties, the following properties:

PREDEFINED PROPERTIES

Remnant flux density

Reference temperature

Temperature coefficient

Nonlinear BH curves

Resistivity at reference temperature

Nonlinear Magnetic Materials Database

Batteries and Fuel Cells Materials Database

The Batteries and Fuel Cells materials database is included with the Batteries & Fuel Cells Module and contains the materials listed in [Table 9-18](#). The material property groups (including all associated properties) are listed in [Table 9-4](#).

Literature references are included as Comments entries in the Batteries & Fuel Cells Materials database. These can be viewed using the Properties window of the Model Builder after a material has been added to the model.

TABLE 9-18: BATTERIES & FUEL CELLS MODULE MATERIALS DATABASE

MATERIAL	INTENDED USE
Sulfuric Acid (Electrolyte, Lead-Acid Battery)	Electrolyte
Pb Electrode (Negative, Lead-Acid Battery)	Negative electrode material
PbO ₂ Electrode (Positive, Lead-Acid Battery)	Positive electrode material
Graphite Electrode, LixC ₆ MCMB (Negative, Li-ion Battery)	Negative electrode materials
Hard Carbon (Negative, Li-ion Battery)	Negative electrode materials
Silicon electrode, LixSi (Negative, Li-ion Battery)	Negative electrode materials
LTO Electrode, Li ₄ Ti ₅ O ₁₂ (Negative, Li-ion Battery)	Negative electrode materials
LCO Electrode, LiCoO ₂ (Positive, Li-ion Battery)	Positive electrode materials

Building Materials Database

The Building materials database contains hygroscopic and thermal properties for materials used with the Heat Transfer Module's Moisture Transport interface and Heat and Moisture Transport multiphysics interface.

In addition to thermal properties (thermal conductivity, density, and heat capacity), the following hygroscopic properties are provided:

- Effective thermal conductivity (SI Unit: W/(m·K))
- Moisture content (SI Unit: kg/m³)
- Moisture diffusivity (SI Unit: m²/s)
- Vapor resistance factor (dimensionless)
- Vapor permeability (SI Unit: s)

Note that for materials intended to be used as vapor barriers, only the vapor resistance factor and vapor permeability are available.

The properties are given either as a constant value, as a piecewise linear function of the temperature or the relative humidity, or as a polynomial approximation function of the temperature or the relative humidity that provides a good agreement with the reference. The table below summarize the materials, their characteristics and their intended use. Also see [References for the Building Materials Database](#).

MATERIAL	USAGE	CHARACTERISTICS	REFERENCE
Concrete	Building structure	-	Ref. 3
Lime silica brick	Building structure	-	Ref. 3
Wood, pine	Studs, panels	Nominal thickness = 10 mm	Ref. 1, Ref. 2
Gypsum board	Interior board	Nominal thickness = 13 mm	Ref. 1, Ref. 2
Glass wool board	Sheathing	Nominal thickness = 30 mm	Ref. 1, Ref. 2
Cellulose board	Sheathing	Nominal thickness = 25 mm	Ref. 1, Ref. 2
Glass wool batt	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Cellulose batt	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Cellulose (loose)	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Plastic coated paper	Vapor/air barrier	-	Ref. 1, Ref. 2
Expanded polystyrene board (EPS)	Thermal insulation, vapor/air barrier	Board from molded blocks conform to norm EN 13163	Ref. 4
Extruded polystyrene board (XPS)	Thermal insulation, vapor/air barrier	Board of thickness < 60mm, without any occluded gas other than air and CO ₂ , conform to norm EN 13164	Ref. 4

Equilibrium Discharge Materials Database

The Equilibrium Discharge materials database is included with the Plasma Module and contains the materials listed in [Table 9-19](#). The material property groups (including all associated properties) are listed in [Table 9-6](#).

TABLE 9-19: EQUILIBRIUM DISCHARGE MATERIALS DATABASE

MATERIAL
Air
Argon
Helium
Hydrogen
Nitrogen
Oxygen

Liquids and Gases Materials Database

The Liquids and Gases Materials database contains thermal and fluid dynamic properties for a set of common liquids and gases. All properties are given as functions of temperature and at atmospheric pressure, except the density, which for gases is also a function of the local pressure. The database also contains surface and interface tensions for a selected set of liquid/gas and liquid/liquid systems. All functions are based on data collected from

scientific publications. This database is included in the Acoustics Module, CFD Module, Chemical Reaction Engineering Module, Heat Transfer Module, MEMS Module, Pipe Flow Module, and Subsurface Flow Module,

TABLE 9-20: LIQUIDS AND GASES MATERIALS

GROUP	MATERIAL	GROUP	MATERIAL
Gases	Air	Liquids	Engine oil
References 1, 2, 7, and 8	Nitrogen	References 2, 3, 4, 5, 6, 7, 9, 10, and 11	Ethanol
	Oxygen		Diethyl ether
	Carbon dioxide		Ethylene glycol
	Hydrogen		Gasoline
	Helium		Glycerol
	Steam		Heptane
	Propane		Mercury
	Ethanol vapor		Toluene
	Diethyl ether vapor		Transformer oil
	Freon 12 vapor		Water
	SiF ₄		R-134A (C ₂ H ₂ F ₄)
			R-22 (CHClF ₂)

MEMS Materials Database

The MEMS materials database, included in the MEMS Module and Structural Mechanics Module, contains several materials commonly used in MEMS applications. The materials are divided into metals, semiconductors, insulators, and polymers.

The basic structure of the library comes from the book *Microsensors, MEMS, and Smart Devices* (Ref. 1). The material properties come from two primary sources: the *CRC Handbook of Chemistry and Physics* (Ref. 2) and *MacMillan's Chemical and Physical Data* (Ref. 3). Some of the mechanical properties in the library are more MEMS-specific values from *The MEMS Handbook* (Ref. 4), and most of the semiconductor properties are values from Ref. 5. Most of the PDMS material properties are based on Ref. 7, where Young's modulus is based on Ref. 8.

Ref. 6 provides a valuable resource for cross-checking the insulation material properties.

TABLE 9-21: MEMS MATERIALS

MATERIAL
Metals
Al - Aluminum/Aluminium
Ag - Silver
Au - Gold
Cr - Chrome
Cu - Copper
In - Indium
Ti - Titanium
Fe - Iron
Ni - Nickel
Pb - Lead
Pd - Palladium
Pt - Platine
Sb - Antimon

TABLE 9-21: MEMS MATERIALS

MATERIAL
W - Tungsten
Semiconductors
Diamond (100)
GaAs - Gallium arsenide
Ge - Germanium
InSb - Indium antimonide
Si - Polycrystalline silicon
Si - Silicon (single-crystal, isotropic)
Si - Silicon (single-crystal, anisotropic)
Insulators
Al ₂ O ₃ - Aluminum oxide/Aluminium oxide
SiC (6H) - Silicon carbide
Si ₃ N ₄ - Silicon nitride
SiO ₂ - Silicon oxide
ZnO - Zinc oxide
Borosilicate
Polymers
Nylon
PDMS - Polydimethylsiloxane
PMMA - Poly methyl methacrylate
Polymide
Polyethylene
PTFE - Polytetrafluoroethylene
PVC - Polyvinyl chloride

Nonlinear Magnetic Materials Database

The Nonlinear Magnetic materials database is included with the AC/DC Module and has properties, such as nonlinear magnetization curves, for a large set of ferromagnetic alloys like various types of steel.

Piezoelectric Materials Database

The Piezoelectric materials database, included in the Acoustics Module, MEMS Module, and Structural Mechanics Module, contains the following materials:

MATERIAL
Barium sodium niobate
Barium titanate
Barium titanate (poled)
Lithium niobate
Lithium tantalate
Lead zirconate titanate (PZT-2), (PZT-4), (PZT-4D), (PZT-5A), (PZT-5H), (PZT-5J), (PZT-7A), and (PZT-8)
Quartz LH (1949 IRE), RH (1949 IRE), LH (1978 IEEE), RH (1978 IEEE)
Rochelle salt
Bismuth germanate
Cadmium sulfide
Gallium arsenide
Tellurium dioxide
Zinc oxide
Zinc sulfide
Ammonium dihydrogen phosphate
Aluminum nitride

All materials define the following material properties needed for piezoelectric modeling:

MATERIAL PROPERTY	DESCRIPTION
c_E	Elasticity matrix
e	Coupling matrix, stress-charge

MATERIAL PROPERTY	DESCRIPTION
ϵ_{rS}	Relative permittivity, stress-charge
s_E	Compliance matrix
d	Coupling matrix, strain-charge
ϵ_{rT}	Relative permittivity, strain-charge
ρ	Density

Piezoresistivity Materials Database

The Piezoresistivity materials database is included with the MEMS Module and contains the following materials:

MATERIAL
p-Silicon (single-crystal, lightly doped)
n-Silicon (single-crystal, lightly doped)
p-Silicon (polycrystalline, lightly doped)
n-Silicon (polycrystalline, lightly doped)

All materials define the following material properties needed for modeling the piezoresistance effect:

MATERIAL PROPERTY	DESCRIPTION
D	Elasticity matrix
DVo	Elasticity matrix, Voigt notation
ρ	Density
ϵ_r	Relative permittivity
σ	Electrical conductivity
Π	Piezoresistive coupling matrix
m_l	Elastoresistive coupling matrix

Both the electrical conductivity and the piezoresistive or elastoresistive coupling matrix are strong functions of the material dopant density. The material models include appropriate functions, although the piezoresistive and elastoresistive matrices scale only with the conductivity, which is appropriate only at lower dopant densities (below approximately 10^{16} cm^{-3}). The low doping level piezoresistance and elastoresistance values are based on those given in [Ref. 1](#). The conductivity is computed from an empirical functional fit to experimental data given in equation 8 of [Ref. 2](#). Data on the piezoresistance properties of Silicon at higher doping levels is available in [Ref. 3](#) and [Ref. 4](#). Because this data does not include all components of the coupling matrix, it is not included in the material models.

The dopant density must be entered for the material as a model input in the piezoresistive or conductive material node. It can be entered as a constant value or as an expression (for example, a spatially varying function could be used).

Optical Materials Database

The Optical materials database is included with the Ray Optics Module and the Wave Optics Module. It contains many optical materials subdivided into these categories: Inorganic Materials, Organic Materials, Glasses, and Miscellaneous Materials. The material properties are frequency-dependent values for the refractive index and its imaginary part. The values are based on data from [Ref. 1](#).

RF Materials Database

The RF materials database is included with the RF Module. It contains a number of substrate materials that assist in modeling RF components. Dielectric properties, like the real part of the relative permittivity and the loss tangent, including the frequency dependence, are included. The database includes material properties from following companies:

- Rogers corporation
- Isola group

Among the materials, the database includes laminates and materials from Rogers Corporation. The laminate and materials trademarks are trademarks or registered trademarks of Rogers Corporation and/or its subsidiaries and joint ventures. All other trademarks are trademarks of their respective companies.

Semiconductor Materials Database

The Semiconductor materials database is included with the Semiconductor Module and contains the materials listed in [Table 9-22](#). The material property groups (including all associated properties) are listed in [Table 9-10](#).

The Silicon material contains parameters for all material property groups, while the other materials contain only the material parameters in the Semiconductor and Basic material groups.

[Table 9-10](#) also gives the references used for the silicon material properties. The material properties for materials other than Silicon are obtained from [Ref. 9](#) and [Ref. 10](#).

TABLE 9-22: SEMICONDUCTOR MODULE MATERIALS DATABASE

MATERIAL
Si - Silicon
Ge - Germanium
GaAs - Gallium arsenide
Al(x)Ga(1-x)As - Aluminium gallium arsenide
GaN (Wurtzite) - Gallium nitride
GaN (Zinc Blende) - Gallium nitride
GaP - Gallium phosphide
GaSb - Gallium antimonide
InAs - Indium arsenide
InP - Indium phosphide
InSb - Indium antimonide

Thermoelectric Materials Database

The Thermoelectric materials database is included with the Heat Transfer Module and contains bismuth telluride (Bi_2Te_3) and lead telluride (PbTe) materials for use with the Thermoelectric Effect interface.

The AC/DC Interfaces

This chapter explains the physics interfaces for modeling electromagnetics, which are found under the **AC/DC** branch (). It also contains sections about general fundamentals and theory for electric fields.

The Electromagnetics Interfaces

For simulating electromagnetic fields, COMSOL Multiphysics has three physics interfaces.

With the first two, you can perform static simulations to solve for electric properties:

- Electrostatics
- Electric Currents
- Magnetic Fields

These interfaces are available in all space dimensions.

For 2D axisymmetric and 2D geometries, you can use the Magnetic Fields interface to perform magnetostatic simulations.

This section begins with a brief introduction to electromagnetics and a definition of the electromagnetic quantities. Then it describes each of the physics interfaces in detail.

The optional AC/DC Module contains specialized and extended interfaces for electromagnetic simulations, for example, for computations of inductors and capacitors. The optional RF Module includes interfaces for simulating electromagnetic wave propagation that are especially useful in microwave engineering and photonics.

Fundamentals of Electromagnetics

Maxwell's Equations

The problem of electromagnetic analysis on a macroscopic level is that of solving *Maxwell's equations* subject to certain boundary conditions. Maxwell's equations are a set of equations, written in differential or integral form, stating the relationships between the fundamental electromagnetic quantities. These quantities are:

- Electric field intensity **E**
- Electric displacement or electric flux density **D**
- Magnetic field intensity **H**
- Magnetic flux density **B**
- Current density **J**
- Electric charge density ρ

The equations can be formulated in differential form or integral form. The differential form is presented here because it leads to differential equations that the finite element method can handle. For general time-varying fields, Maxwell's equations can be written as:

$$\begin{aligned}\nabla \times \mathbf{H} &= \mathbf{J} + \frac{\partial \mathbf{D}}{\partial t} \\ \nabla \times \mathbf{E} &= -\frac{\partial \mathbf{B}}{\partial t} \\ \nabla \cdot \mathbf{D} &= \rho \\ \nabla \cdot \mathbf{B} &= 0\end{aligned}$$

The first two equations are also referred to as *Maxwell-Ampère's law* and *Faraday's law*, respectively. Equation three and four are two forms of *Gauss' law*: the electric and magnetic form, respectively.

Another fundamental equation is the *equation of continuity*

$$\nabla \cdot \mathbf{J} = -\frac{\partial \rho}{\partial t}$$

Out of the five equations mentioned, only three are independent. The first two combined with either the electric form of Gauss' law or the equation of continuity form such an independent system.

Constitutive Relations

To obtain a closed system, the equations include *constitutive relations* that describe the macroscopic properties of the medium. They are given as:

$$\begin{aligned}\mathbf{D} &= \epsilon_0 \mathbf{E} + \mathbf{P} \\ \mathbf{B} &= \mu_0 (\mathbf{H} + \mathbf{M}) \\ \mathbf{J} &= \sigma \mathbf{E}\end{aligned}\tag{10-1}$$

where ϵ_0 is the permittivity of vacuum, μ_0 is the permeability of vacuum, and σ is the electrical conductivity. In the SI system, the permeability of vacuum is chosen to be $4\pi \cdot 10^{-7}$ H/m. The velocity of an electromagnetic wave in a vacuum is given as c_0 and the permittivity of a vacuum is derived from the relation:

$$\epsilon_0 = \frac{1}{c_0^2 \mu_0} = 8.854 \cdot 10^{-12} \text{ F/m} \approx \frac{1}{36\pi} \cdot 10^{-9} \text{ F/m}$$

The electromagnetic constants ϵ_0 , μ_0 , and c_0 are available in COMSOL Multiphysics as predefined physical constants.

The *electric polarization vector* **P** describes how the material is polarized when an electric field **E** is present. It can be interpreted as the volume density of *electric dipole* moments. **P** is generally a function of **E**. Some materials can have a nonzero **P** also when there is no electric field present.

The *magnetization vector* **M** similarly describes how the material is magnetized when a magnetic field **H** is present. It can be interpreted as the volume density of *magnetic dipole* moments. **M** is generally a function of **H**. Permanent magnets, for instance, have a nonzero **M** also when there is no magnetic field present.

For linear materials, the polarization is directly proportional to the electric field, $\mathbf{P} = \epsilon_0 \chi_e \mathbf{E}$, where χ_e is the electric susceptibility. Similarly in linear materials, the magnetization is directly proportional to the magnetic field, $\mathbf{M} = \chi_m \mathbf{H}$, where χ_m is the magnetic susceptibility. For such materials, the constitutive relations are:

$$\begin{aligned}\mathbf{D} &= \epsilon_0(1 + \chi_e)\mathbf{E} = \epsilon_0\epsilon_r\mathbf{E} = \epsilon\mathbf{E} \\ \mathbf{B} &= \mu_0(1 + \chi_m)\mathbf{H} = \mu_0\mu_r\mathbf{H} = \mu\mathbf{H}\end{aligned}$$

The parameter ϵ_r is the relative permittivity and μ_r is the relative permeability of the material. Usually these are scalar properties but can, in the general case, be 3-by-3 tensors when the material is anisotropic. The properties ϵ and μ (without subscripts) are the permittivity and permeability of the material, respectively.

GENERALIZED CONSTITUTIVE RELATIONS

The [Charge Conservation](#) node describes the macroscopic properties of the medium (relating the electric displacement **D** with the electric field **E**) and the applicable material properties.

For nonlinear materials, a generalized form of the constitutive relationships is useful. The relationship used for electric fields is $\mathbf{D} = \epsilon_0\epsilon_r\mathbf{E} + \mathbf{D}_r$, where \mathbf{D}_r is the *remanent displacement*, which is the displacement when no electric field is present.

Similarly, a generalized form of the constitutive relation for the magnetic field is

$$\mathbf{B} = \mu_0\mu_r\mathbf{H} + \mathbf{B}_r$$

where \mathbf{B}_r is the *remanent magnetic flux density*, which is the magnetic flux density when no magnetic field is present.

For some materials, there is a nonlinear relationship between **B** and **H** such that

$$\mathbf{B} = f(|\mathbf{H}|)$$

The relation defining the current density is generalized by introducing an externally generated current **J_e**. The resulting constitutive relation is $\mathbf{J} = \sigma\mathbf{E} + \mathbf{J}_e$.

Potentials

Under certain circumstances, it can be helpful to formulate the problems in terms of the electric scalar potential **V** and the magnetic vector potential **A**. They are given by the equalities:

$$\mathbf{B} = \nabla \times \mathbf{A}$$

$$\mathbf{E} = -\nabla V - \frac{\partial \mathbf{A}}{\partial t}$$

The defining equation for the magnetic vector potential is a direct consequence of the magnetic Gauss' law. The electric potential results from Faraday's law.

Material Properties

Until now, there has only been a formal introduction of the constitutive relations. These seemingly simple relations can be quite complicated at times. There are four main groups of materials for which they require some consideration. A given material can belong to one or more of these groups.

Inhomogeneous Materials Inhomogeneous materials are the least complicated. An inhomogeneous medium is one in which the constitutive parameters vary with the space coordinates so that different field properties prevail at different parts of the material structure.

Anisotropic Materials For anisotropic materials, the field relationships at any point differ for different directions of propagation. This means that a 3-by-3 tensor is necessary to properly define the constitutive relationships. If this tensor is symmetric, the material is often referred to as *reciprocal*. In such cases, rotate the coordinate system such that a diagonal matrix results. If two of the diagonal entries are equal, the material is *uniaxially anisotropic*. If none of the elements have the same value, the material is *biaxially anisotropic* (Ref. 2). Anisotropic parameters are needed, for example, to examine permittivity in crystals (Ref. 2) and when working with conductivity in solenoids.

Nonlinear Materials Nonlinearity is the effect of variations in permittivity or permeability with the intensity of the electromagnetic field. Nonlinearity also includes hysteresis effects, where not only the current field intensities influence the physical properties of the material, but also the history of the field distribution.

Dispersive Materials Dispersion describes changes in a wave's velocity with wavelength. In the frequency domain, dispersion is expressed with a frequency dependence of the constitutive laws.

About the Boundary and Physics Interface Conditions

To get a full description of an electromagnetics problem, boundary conditions must be specified at material interfaces and physical boundaries. At interfaces between two media, the boundary conditions can be expressed mathematically as

$$\begin{aligned}\mathbf{n}_2 \times (\mathbf{E}_1 - \mathbf{E}_2) &= \mathbf{0} \\ \mathbf{n}_2 \cdot (\mathbf{D}_1 - \mathbf{D}_2) &= \rho_s \\ \mathbf{n}_2 \times (\mathbf{H}_1 - \mathbf{H}_2) &= \mathbf{J}_s \\ \mathbf{n}_2 \cdot (\mathbf{B}_1 - \mathbf{B}_2) &= 0\end{aligned}$$

where ρ_s and \mathbf{J}_s denote surface charge density and surface current density, respectively, and \mathbf{n}_2 is the outward normal from medium two. Of these four conditions, only two are independent. This is an overdetermined system of equations, so it needs to be reduced. First select either equation one or equation four. Then select either equation two or equation three. Together these selections form a set of two independent conditions.

From these relationships, the interface condition is derived for the current density,

$$\mathbf{n}_2 \cdot (\mathbf{J}_1 - \mathbf{J}_2) = -\frac{\partial \rho_s}{\partial t}$$

INTERFACE BETWEEN A DIELECTRIC AND A PERFECT CONDUCTOR

A perfect conductor has infinite electrical conductivity and thus no internal electric field. Otherwise, it would produce an infinite current density according to the third fundamental constitutive relation. At an interface between a dielectric and a perfect conductor, the boundary conditions for the **E** and **D** fields are simplified. Assume that subscript 1 corresponds to a perfect conductor; then $\mathbf{D}_1 = \mathbf{0}$ and $\mathbf{E}_1 = \mathbf{0}$ in the relationships just given. If it is a time-varying case, then $\mathbf{B}_1 = \mathbf{0}$ and $\mathbf{H}_1 = \mathbf{0}$ as well, as a consequence of Maxwell's equations. The result is the following set of boundary conditions for the fields in the dielectric medium for the time-varying case:

$$\begin{aligned}-\mathbf{n}_2 \times \mathbf{E}_2 &= 0 \\-\mathbf{n}_2 \times \mathbf{H}_2 &= \mathbf{J}_s \\-\mathbf{n}_2 \cdot \mathbf{D}_2 &= \rho_s \\-\mathbf{n}_2 \cdot \mathbf{B}_2 &= 0\end{aligned}$$

Phasors

Whenever a problem is time-harmonic the fields can be written in the form:

$$\mathbf{E}(\mathbf{r}, t) = \hat{\mathbf{E}}(\mathbf{r}) \cos(\omega t + \phi)$$

Instead of using a cosine function for the time dependence, it is more convenient to use an exponential function, by writing the field as:

$$\mathbf{E}(\mathbf{r}, t) = \hat{\mathbf{E}}(\mathbf{r}) \cos(\omega t + \phi) = \text{Re}(\hat{\mathbf{E}}(\mathbf{r}) e^{j\phi} e^{j\omega t}) = \text{Re}(\tilde{\mathbf{E}}(\mathbf{r}) e^{j\omega t})$$

The field $\tilde{\mathbf{E}}(\mathbf{r})$ is a *phasor*, which contains amplitude and phase information of the field but is independent of t . One thing that makes the use of phasors suitable is that a time derivative corresponds to a multiplication by $j\omega$,

$$\frac{\partial \mathbf{E}}{\partial t} = \text{Re}(j\omega \tilde{\mathbf{E}}(\mathbf{r}) e^{j\omega t})$$

If the fields satisfy a linear time-dependent equation, then the corresponding phasors must satisfy a similar equation in which the time derivatives are replaced by a factor $j\omega$. All time-harmonic equations in the AC/DC Module are expressed as equations for the phasors. (The tilde is dropped from the variable denoting the phasor.)

The frequency domain formulation is only applicable for equations linear in the fields. In particular, it cannot be used with materials whose properties depend on the fields themselves (nonlinear materials). See [Effective Nonlinear Magnetic Constitutive Relations](#) for a formulation that approximates nonlinear magnetic constitutive relations in time-harmonic problems.

When analyzing the solution of a time-harmonic equation, it is important to remember that the field that has been calculated is a phasor and not a physical field.

For example, all plot functions visualize $\text{Re}(\tilde{\mathbf{E}}(\mathbf{r}))$ by default, which is \mathbf{E} at time $t = 0$. To obtain the solution at a given time, specify a phase factor in all results pages and in the corresponding functions.

Effective Nonlinear Magnetic Constitutive Relations

The effective constitutive relations can be used to approximate the behavior of a nonlinear magnetic material, such as a saturable material, in a (linear) Frequency Domain study.

The approach consists in replacing the nonlinear material with an inhomogeneous linear material — a material described by a magnetic permeability constant in time but which can be space dependent. The local magnetic permeability is chosen using an approximation criterion, such as, for example, that the cycle-average energy stored must be equal to the nonlinear case. As a consequence, the permeability may depend on the amplitude of the magnetic field and the nonlinear solver is invoked during the solution.

The formulation still applies the assumption of harmonic time dependency of the fields (which are still described as phasors): the fields still oscillate at the given frequency; higher-order harmonic effects, or other similar effects due to the nonlinearity, are not accounted for.

Using this constitutive relation provides a better approximation of the behavior of a nonlinear material in the frequency domain than linearizing the material properties, still avoiding the computational cost of a full transient analysis.

The application Effective Nonlinear Magnetic Curves Calculator in the AC/DC Module Application Library can be used to compute the effective BH or HB curve for a material, starting from its BH or HB curve.

Electromagnetic Forces

The Magnetic Field interface contains a predefined domain-level variable for calculating the Lorentz force, which gives the force distribution exerted on a current-carrying conductor placed in magnetic flux density \mathbf{B} . The Lorentz force is defined as $\mathbf{F} = \mathbf{J} \times \mathbf{B}$.

The Lorentz force gives very good accuracy for electromagnetic force calculations in conducting domains. For nonconducting domains, use a more general method — integrating the Maxwell stress tensor variables over the boundaries of the object for which to calculate the total force. The Maxwell surface stress tensor is available as a boundary variable.

Theory of Electrostatics

The [Electrostatics Interface](#) is available for 3D, 2D in-plane, and 2D axisymmetric components. Applications with electrostatic equations include high-voltage apparatus, electronic devices, and capacitors. The term “statics” is not to be interpreted literally—it is the observation time, or time scale at which the applied excitation changes, that is short compared to the charge relaxation time; also, the electromagnetic wavelength and skin depth are very large compared to the size of the domain of interest.

If you do not know whether to use the Electric Currents or the Electrostatics interface, which both solve for the scalar electric potential V , consider using an explicit charge transport model. See [Charge Relaxation Theory](#).

Charge Relaxation Theory

COMSOL Multiphysics includes physics interfaces for the modeling of static electric fields and currents. Deciding what specific physics interface and study type to select for a particular modeling situation requires a basic understanding of the charge dynamics in conductors.

Physics interfaces for the modeling of dynamic, quasi-static (that is, without including wave propagation effects) electric fields and currents are available with the AC/DC Module and MEMS Module.

The different physics interfaces involving only the scalar electric potential can be interpreted in terms of the charge relaxation process. The fundamental equations involved are *Ohm's law* for the conduction current density

$$\mathbf{J}_c = \sigma \mathbf{E}$$

the *equation of continuity*

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J}_c = 0$$

and *Gauss' law*

$$\nabla \cdot (\epsilon \mathbf{E}) = \rho$$

By combining these, one can deduce the following differential equation for the space charge density in a homogeneous medium

$$\frac{\partial \rho}{\partial t} + \frac{\sigma}{\epsilon} \rho = 0$$

This equation has the solution

$$\rho(t) = \rho_0 e^{-t/\tau}$$

where

$$\tau = \frac{\epsilon}{\sigma}$$

is called the charge relaxation time. For a good conductor like copper, τ is of the order of 10^{-19} s, whereas for a good insulator like silica glass, it is of the order of 10^3 s. For a pure insulator, it becomes infinite.

When modeling real-world devices, there is not only the *intrinsic time scale* of the charge relaxation time but also an *external time scale* t at which a device is energized or the observation time. It is the relation between the

external time scale and the charge relaxation time that determines what physics interface and study type to use. The results are summarized in [Table 10-1](#) below,

TABLE 10-1: SUITABLE PHYSICS INTERFACE AND STUDY TYPE FOR DIFFERENT TIME-SCALE REGIMES.

CASE	PHYSICS INTERFACE	STUDY TYPE
$\tau \gg t$	Electrostatics	Stationary
$\tau \ll t$	Electric Currents	Stationary
$\tau \sim t$	Electric Currents	Time Dependent or, with the AC/DC Module, MEMS Module, or Semiconductor Module, Frequency Domain

FIRST CASE: $\tau \gg t$

If the external time scale is short compared to the charge relaxation time, the charges do not have time to redistribute to any significant degree. Thus the charge distribution can be considered as a given model input. The best approach is to solve the Electrostatics formulation using the electric potential V .

By combining the definition of the potential with Gauss' law, you can derive the classical Poisson's equation. Under static conditions, the electric potential V is defined by the equivalence $\mathbf{E} = -\nabla V$. Using this together with the constitutive relation $\mathbf{D} = \epsilon_0 \mathbf{E} + \mathbf{P}$ between \mathbf{D} and \mathbf{E} , you can rewrite Gauss' law as a variant of Poisson's equation

$$-\nabla \cdot (\epsilon_0 \nabla V - \mathbf{P}) = \rho$$

This equation is used in the Electrostatics interface. It is worth noting that Gauss' law does not require the charge distribution to be static. Thus, provided dynamics are slow enough that induced electric fields can be neglected and hence a scalar electric potential is justified, the formulation can be used also in the Time Dependent study type. That typically involves either prescribing the charge dynamics or coupling a separate formulation for this.

	Such separate charge transport formulations can be found in the Plasma Module, the Semiconductor Module, and the Chemical Reaction Engineering Module.
---	--

SECOND CASE: $\tau \ll t$

If the external time scale is long compared to the charge relaxation time, the stationary solution to the equation of continuity has been reached. In a stationary coordinate system, a slightly more general form of Ohm's law than above states that

$$\mathbf{J}_c = \sigma \mathbf{E} + \mathbf{J}_e$$

where \mathbf{J}_e is an externally generated current density. The static form of the equation of continuity then reads

$$\nabla \cdot \mathbf{J}_c = -\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = 0$$

To handle current sources, the equation can be generalized to

$$-\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = Q_j$$

This equation is used in the static study type for the Electric Currents interface.

Electrostatics Equations

Under static conditions, the electric potential, V , is defined by the relationship:

$$\mathbf{E} = -\nabla V$$

Combining this equation with the constitutive relationship $\mathbf{D} = \epsilon_0 \mathbf{E} + \mathbf{P}$ between the electric displacement \mathbf{D} and the electric field \mathbf{E} , it is possible to represent Gauss' law as the following equation:

$$-\nabla \cdot (\epsilon_0 \nabla V - \mathbf{P}) = \rho$$

In this equation, the physical constant, ϵ_0 (SI unit: F/m) is the permittivity of vacuum, \mathbf{P} (SI unit: C/m²) is the electric polarization vector, and ρ (SI unit: C/m³) is a space charge density. This equation describes the electrostatic field in dielectric materials.

For in-plane 2D modeling, the Electrostatics interface assumes a symmetry where the electric potential varies only in the x and y directions and is constant in the z direction. This implies that the electric field, \mathbf{E} , is tangential to the xy -plane. With this symmetry, the same equation is solved as in the 3D case. The physics interface solves the following equation where d is the thickness in the z direction:

$$-\nabla \cdot d(\epsilon_0 \nabla V - \mathbf{P}) = \rho$$

The axisymmetric version of the physics interface considers the situation where the fields and geometry are axially symmetric. In this case, the electric potential is constant in the φ direction, which implies that the electric field is tangential to the rz -plane.

The Electrostatics Interface in Time Dependent or Frequency Domain Studies

The **Electrostatics Interface** can also be solved in a dynamic study (Time Dependent or Frequency Domain). The equation system solved, however, is typically always the one presented in the previous section for the stationary case, in which no transient electromagnetic effects are taken into account. The difference is that the sources of the problem (charge densities, electric potential) are assumed to be time-varying (in a Time Dependent study) or time-harmonic (in a Frequency Domain study).

The support for dynamic studies simplifies the coupling of the Electrostatics interface with other physics interfaces. Using the physics interface in a dynamic study is a valid approximation only if the time-scale (or the frequency) of the study is so slow that transient electromagnetic effects can be neglected; for example, in acoustic or structural problems.

The Electrostatics interface also supports the small-signal analysis study sequence, which can be used when a time-harmonic perturbation is superposed on a static bias charge or voltage.

Theory of Electric Currents

The [Electric Currents Interface](#) solves a current conservation problem for the scalar electric potential V and is available for 3D, 2D in-plane, and 2D axisymmetric components. Electrolysis and the computation of resistances of grounding plates are examples that involve conductive media with electrical conductivities and electric currents. If you are uncertain of whether to use the Electric Currents or the Electrostatics interface, which both solve for the scalar electric potential V , refer to the section on [Charge Relaxation Theory](#).

Electric Currents Equations in Steady State

When handling stationary electric currents in conductive media you must consider the stationary equation of continuity. In a stationary coordinate system, the point form of *Ohm's law* states that:

$$\mathbf{J} = \sigma \mathbf{E} + \mathbf{J}_e$$

where σ is the electrical conductivity (SI unit: S/m), and \mathbf{J}_e is an externally generated current density (SI unit: A/m²). The static form of the equation of continuity then states:

$$\nabla \cdot \mathbf{J} = -\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = 0$$

To handle current sources, you can generalize the equation to:

$$-\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = Q_j$$

In planar 2D the Electric Currents interface assumes that the model has a symmetry where the electric potential varies only in the x and y directions and is constant in the z direction. This implies that the electric field, \mathbf{E} , is tangential to the xy -plane. The Electric Currents interface then solves the following equation, where d is the thickness in the z direction:

$$-\nabla \cdot d(\sigma \nabla V - \mathbf{J}_e) = dQ_j \quad (10-2)$$

In 2D axisymmetry, the Electric Currents interface considers the situation where the fields and geometry are axially symmetric. In this case, the electric potential is constant in the ϕ direction, which implies that the electric field is tangential to the rz -plane.

Theory of Magnetic Fields

Simulation of magnetic fields is of interest when studying magnets, motors, transformers, and conductors carrying static or alternating currents.

The [Magnetic Fields Interface](#) is used for 3D, 2D in-plane, and 2D axisymmetric components. Unless you have a license for the AC/DC Module, only 2D components involving out-of-plane currents and axisymmetric components involving azimuthal currents are supported.

For a deeper theoretical background to the magnetic vector potential used, see the section starting with [Maxwell's Equations](#).

In this section:

- [Frequency Domain Equation](#)
- [Transient Equation](#)
- [Maxwell's Equations](#)
- [Magnetic and Electric Potentials](#)
- [Gauge Transformations](#)
- [Selecting a Particular Gauge](#)
- [The Gauge and Equation of Continuity for Dynamic Fields](#)
- [Time-Harmonic Magnetic Fields](#)

Magnetostatics Equation

To derive the magnetostatic equation, start with Ampère's law for static cases $\nabla \times \mathbf{H} = \mathbf{J}$. The current is

$$\mathbf{J} = \sigma \mathbf{v} \times \mathbf{B} + \mathbf{J}_e$$

where \mathbf{J}_e is an externally generated current density, and \mathbf{v} is the velocity of the conductor.

Using the definitions of magnetic potential, $\mathbf{B} = \nabla \times \mathbf{A}$ and the constitutive relationship, $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$, rewrite Ampère's law as

$$\nabla \times (\mu_0^{-1} \nabla \times \mathbf{A} - \mathbf{M}) - \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_e$$

which is the equation used in magnetostatics.

Frequency Domain Equation

To derive the time harmonic equation this physics interface solves, start with Ampère's law including displacement currents (then called Maxwell-Ampère's law), as these do not involve any extra computational cost in the frequency domain,

$$\nabla \times \mathbf{H} = \mathbf{J} + \frac{\partial \mathbf{D}}{\partial t} = \sigma \mathbf{E} + \sigma \mathbf{v} \times \mathbf{B} + \mathbf{J}_e + \frac{\partial \mathbf{D}}{\partial t}$$

Now assume time-harmonic fields and use the definitions of the fields,

$$\begin{aligned}\mathbf{B} &= \nabla \times \mathbf{A} \\ \mathbf{E} &= -j\omega \mathbf{A}\end{aligned}$$

and combine them with the constitutive relationships $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$ and $\mathbf{D} = \epsilon_0 \mathbf{E}$ to rewrite Ampère's law as

$$(j\omega\sigma - \omega^2\epsilon_0)\mathbf{A} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_e$$

Transient Equation

The transient equation this physics interface solves is Ampère's law, illustrated here with the constitutive relation $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$.

$$\sigma \frac{\partial \mathbf{A}}{\partial t} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_e$$

Maxwell's Equations

Quasi-static analysis of magnetic and electric fields is valid under the assumption that $\partial \mathbf{D}/\partial t = 0$.

This implies that it is possible to rewrite Maxwell's equations in the following manner:

$$\begin{aligned}\nabla \times \mathbf{H} &= \mathbf{J} = \sigma(\mathbf{E} + \mathbf{v} \times \mathbf{B}) + \mathbf{J}_e \\ \nabla \times \mathbf{E} &= \frac{\partial \mathbf{B}}{\partial t} \\ \nabla \cdot \mathbf{B} &= 0 \\ \nabla \cdot \mathbf{D} &= \rho \\ \nabla \cdot \mathbf{J} &= 0\end{aligned}$$

Here \mathbf{J}_e is an externally generated current density and \mathbf{v} is the velocity of the conductor. The crucial criterion for the quasi-static approximation to be valid is that the currents and electromagnetic fields vary slowly. This means that the dimensions of the structure in the problem need to be small compared to the wavelength.

Magnetic and Electric Potentials

Using the definitions of the potentials,

$$\begin{aligned}\mathbf{B} &= \nabla \times \mathbf{A} \\ \mathbf{E} &= -\nabla V - \frac{\partial \mathbf{A}}{\partial t}\end{aligned}$$

and the constitutive relation $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$, Ampère's law can be rewritten as

$$\sigma \frac{\partial \mathbf{A}}{\partial t} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) + \sigma \nabla V = \mathbf{J}_e \quad (10-3)$$

The equation of continuity, which is obtained by taking the divergence of the above equation, adds the following equation:

$$\nabla \cdot \left(-\sigma \frac{\partial \mathbf{A}}{\partial t} + \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) - \sigma \nabla V + \mathbf{J}_e \right) = 0 \quad (10-4)$$

Equation 10-3 and Equation 10-4 form a system of equations for the two potentials \mathbf{A} and V .

Gauge Transformations

The electric and magnetic potentials are not uniquely defined from the electric and magnetic fields through

$$\mathbf{E} = -\frac{\partial \mathbf{A}}{\partial t} - \nabla V$$
$$\mathbf{B} = \nabla \times \mathbf{A}$$

Introducing two new potentials

$$\tilde{\mathbf{A}} = \mathbf{A} + \nabla \Psi$$
$$\tilde{V} = V - \frac{\partial \Psi}{\partial t}$$

gives the same electric and magnetic fields:

$$\mathbf{E} = -\frac{\partial \mathbf{A}}{\partial t} - \nabla V = -\frac{\partial(\tilde{\mathbf{A}} - \nabla \Psi)}{\partial t} - \nabla\left(\tilde{V} + \frac{\partial \Psi}{\partial t}\right) = -\frac{\partial \tilde{\mathbf{A}}}{\partial t} - \nabla \tilde{V}$$
$$\mathbf{B} = \nabla \times \mathbf{A} = \nabla \times (\tilde{\mathbf{A}} - \nabla \Psi) = \nabla \times \tilde{\mathbf{A}}$$

The variable transformation of the potentials is called a *gauge transformation*. To obtain a unique solution, choose the gauge—that is, put constraints on Ψ that make the solution unique. Another way of expressing this additional condition is to put a constraint on $\nabla \cdot \mathbf{A}$. A vector field is uniquely defined up to a constant if both $\nabla \cdot \mathbf{A}$ and $\nabla \times \mathbf{A}$ are given. This is called *Helmholtz's theorem*.

One particular gauge is the *Coulomb gauge* given by the constraint: $\nabla \cdot \mathbf{A} = 0$.

Selecting a Particular Gauge

It is important to observe that in the dynamic case, \mathbf{A} and V are coupled via the selected gauge. For a dynamic formulation, it is also possible to select a Ψ such that the scalar electric potential vanishes and only the magnetic vector potential has to be considered. The dynamic formulations (Frequency Domain and Time Dependent study types) of the Magnetic Fields interface are operated in this gauge as it involves only \mathbf{A} . In the static limit, \mathbf{A} and V are not coupled via the gauge selection and thus any gauge can be chosen for \mathbf{A} when performing magnetostatic modeling.

The Gauge and Equation of Continuity for Dynamic Fields

After eliminating the electric potential by choosing the appropriate gauge and disregarding the velocity term, the equation of continuity obtained by taking the divergence of Ampère's law reads:

$$\nabla \cdot \left(-\sigma \frac{\partial \mathbf{A}}{\partial t} + \mathbf{J}_e \right) = 0$$

It is clear that unless the electrical conductivity is uniform, the particular gauge used to eliminate V cannot be the Coulomb gauge as that would violate the equation of continuity and would thereby also violate Ampère's law.

Time-Harmonic Magnetic Fields

In the time-harmonic case, there is no computational cost for including the displacement current in Ampère's law (then called Maxwell-Ampère's law):

$$\nabla \times \mathbf{H} = \mathbf{J} = \sigma(\mathbf{E} + \mathbf{v} \times \mathbf{B}) + (j\omega \mathbf{D} + \mathbf{J}_e)$$

In the transient case, the inclusion of this term leads to a second-order equation in time, but in the harmonic case there are no such complications. Using the definition of the electric and magnetic potentials, the system of equations becomes:

$$\begin{aligned} -\nabla \cdot ((j\omega\sigma - \omega^2\epsilon_0)\mathbf{A} - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) + (\sigma + j\omega\epsilon_0)\nabla V - (\mathbf{J}_e + j\omega\mathbf{P})) &= 0 \\ (j\omega\sigma - \omega^2\epsilon_0)\mathbf{A} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) + (\sigma + j\omega\epsilon_0)\nabla V &= \mathbf{J}_e + j\omega\mathbf{P} \end{aligned}$$

The constitutive relation $\mathbf{D} = \epsilon_0\mathbf{E} + \mathbf{P}$ has been used for the electric field.

To obtain a particular gauge that reduces the system of equation, choose $\Psi = -jV/\omega$ in the gauge transformation. This gives:

$$\tilde{\mathbf{A}} = \mathbf{A} - \frac{j}{\omega}\nabla V \quad \tilde{V} = 0$$

When \tilde{V} vanishes from the equations, only the second one is needed,

$$(j\omega\sigma - \omega^2\epsilon_0)\tilde{\mathbf{A}} + \nabla \times (\mu_0^{-1}\nabla \times \tilde{\mathbf{A}} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \tilde{\mathbf{A}}) = \mathbf{J}_e + j\omega\mathbf{P}$$

Working with $\tilde{\mathbf{A}}$ is often the best option when it is possible to specify all source currents as external currents \mathbf{J}_e or as surface currents on boundaries.

The Electrostatics Interface

The **Electrostatics (es)** interface (), found under the **AC/DC** branch () when adding a physics interface, is used to compute the electric field, electric displacement field, and potential distributions in dielectrics under conditions where the electric charge distribution is explicitly prescribed. The formulation is stationary except for use together with other physics interfaces. Eigenfrequency, frequency-domain, small-signal analysis, and time-domain modeling are supported in all space dimensions.

The physics interface solves Gauss' Law for the electric field using the scalar electric potential as the dependent variable.

Charge Conservation is the main node, which adds the equation for the electric potential and has a Settings window for defining the constitutive relation for the electric displacement field and its associated properties such as the relative permittivity.

When this physics interface is added, these default nodes are also added to the **Model Builder — Charge Conservation**, **Zero Charge** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and space charges. You can also right-click **Electrostatics** to select physics features from the context menu.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the **name** string must be unique. Only letters, numbers, and underscores (`_`) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `es`.

CROSS-SECTION AREA (1D COMPONENTS)

For 1D components, enter a default value for the **Cross-section area A** (SI unit: m^2). The default value of 1 is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 1D equation identical to the equation used for 3D components. See also [Change Cross Section](#).

THICKNESS (2D COMPONENTS)

For 2D components, enter a default value for the **Out-of-plane thickness d** (SI unit: m). The default value of 1 is typically not representative for a thin dielectric medium, for example. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components. See also [Change Thickness \(Out-of-Plane\)](#).

PHYSICS-CONTROLLED MESH

Select the **Enable** check box to allow the physics interface to control the meshing process. Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to set up automatically an appropriate mesh sequence.

DEPENDENT VARIABLES

The dependent variable is the **Electric potential V**. You can change its name, which changes both the field name and the variable name. If the new name coincides with the name of another electric potential field in the model, the physics interfaces shares degrees of freedom. The new name must not coincide with the name of a field of another type or with a component name belonging to some other field.

DISCRETIZATION

To display all settings available in this section, click the **Show** button () and select **Advanced Physics Options**.

	In the <i>COMSOL Multiphysics Reference Manual</i> , see Table 2-3 for links to common sections and Table 2-4 to common feature nodes. You can also search for information: press F1 to open the Help window or Ctrl+F1 to open the Documentation window.
	<ul style="list-style-type: none">• Domain, Boundary, Edge, Point, and Pair Nodes for the Electrostatics Interface• Theory of Electrostatics
	<i>Electric Sensor</i> : Application Library path COMSOL_Multiphysics/Electromagnetics/electric_sensor

Domain, Boundary, Edge, Point, and Pair Nodes for the Electrostatics Interface

The Electrostatics interface has these domain, boundary, edge, point, and pair nodes available.

ABOUT THE BOUNDARY CONDITIONS

The relevant physics interface condition at interfaces between different media is

$$\mathbf{n}_2 \cdot (\mathbf{D}_1 - \mathbf{D}_2) = \rho_s$$

In the absence of surface charges, this condition is fulfilled by the natural boundary condition

$$\mathbf{n} \cdot [(\epsilon_0 \nabla V - \mathbf{P})_1 - (\epsilon_0 \nabla V - \mathbf{P})_2] = -\mathbf{n} \cdot (\mathbf{D}_1 - \mathbf{D}_2) = 0$$

AVAILABLE NODES

These nodes, listed in alphabetical order, are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or right-click to access the context menu (all users). Also see [Table 10-2](#) for a list of interior and exterior boundary conditions, including edge, point, and pair availability.

	In general, to add a node, go to the Physics toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the Attributes menu.
--	---

Ground	x	x	edges, points, and pairs
Periodic Condition		x	not applicable
Surface Charge Density	x	x	pairs
Thin Low Permittivity Gap	x		not applicable
Zero Charge (the default)	x	x	pairs

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the model that is valid on the axial symmetry boundaries only. There are also **Line Charge (on Axis)** and **Point Charge (on Axis)** available.

In the *COMSOL Multiphysics Reference Manual*, see [Table 2-3](#) for links to common sections and [Table 2-4](#) to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Charge Conservation

The **Charge Conservation** node adds the equations for charge conservation according to Gauss' law for the electric displacement field. It provides an interface for defining the constitutive relation and its associated properties such as the relative permittivity.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Non-solid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

ELECTRIC FIELD

Select a **Constitutive relation** to describe the macroscopic properties of the medium (relating the electric displacement **D** with the electric field **E**) and the applicable material properties, such as the relative permittivity. Select:

- **Relative permittivity** (the default) to use the constitutive relation $\mathbf{D} = \epsilon_0 \epsilon_r \mathbf{E}$. Then the default is to take the **Relative permittivity** ϵ_r (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** and enter values or expressions in the field or matrix. The default is 1.
- **Polarization** to use the constitutive relation $\mathbf{D} = \epsilon_0 \mathbf{E} + \mathbf{P}$. Then enter the components based on space dimension for the **Polarization** vector **P** (SI unit: C/m²). The defaults are 0 C/m².
- **Remanent electric displacement** to use constitutive relation $\mathbf{D} = \epsilon_0 \epsilon_r \mathbf{E} + \mathbf{D}_r$, where \mathbf{D}_r is the remanent displacement (the displacement when no electric field is present). Then the default is to take the **Relative permittivity** ϵ_r (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** and enter values or expressions in the field or matrix. Then enter the components based on space dimension for the **Remanent electric displacement** **D_r** (SI unit: C/m²). The defaults are 0 C/m².

Initial Values

The **Initial Values** node adds an initial value for the electric potential **V** that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear solver.

INITIAL VALUES

Enter a value or expression for the initial value of the **Electric potential** **V** (SI unit: V). The default value is 0 V.

Space Charge Density

The **Space Charge Density** node adds a space charge density ρ , which appears on the right-hand side of the equation that the physics interface defines.

SPACE CHARGE DENSITY

Enter a value or expression for the **Space charge density** ρ_v (SI unit: C/m³). The default is 0 C/m³.

Zero Charge

The **Zero Charge** node adds the condition that there is zero charge on the boundary so that $\mathbf{n} \cdot \mathbf{D} = 0$. This boundary condition is also applicable at symmetry boundaries where the potential is known to be symmetric with respect to the boundary. This is the default boundary condition at exterior boundaries. At interior boundaries, it means that

no displacement field can penetrate the boundary and that the electric potential is discontinuous across the boundary.

Ground

The **Ground** node implements ground (zero potential) as the boundary condition $V = 0$.

Ground means that there is a zero potential on the boundary. This boundary condition is also applicable at symmetry boundaries where the potential is known to be antisymmetric with respect to the boundary.

For some physics interfaces, also select additional **Ground** nodes from the **Edges** (3D components) or **Points** (2D and 3D components) submenus. For 2D axisymmetric components, it can be applied on the Symmetry axis.

BOUNDARY, EDGE, OR POINT SELECTION

Beware that constraining the potential on edges or points in 3D or on points in 2D usually yields a current outflow that is mesh dependent.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Electric Potential

The **Electric Potential** node provides an electric potential V_0 as the boundary condition $V = V_0$.

Because the electric potential is being solved for in the physics interface, the value of the potential is typically defined at some part of the geometry. For some physics interfaces, also select additional **Electric Potential** nodes from the **Edges** (3D components) or **Points** (2D and 3D components) submenus. For 2D axisymmetric components, it can be applied on the symmetry axis.

BOUNDARY, EDGE, OR POINT SELECTION

Beware that constraining the potential on edges or points in 3D or on points in 2D usually yields a current outflow that is mesh dependent.

ELECTRIC POTENTIAL

Enter the value or expression for the **Electric potential** V_0 (SI unit: V). The default is 0 V.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Surface Charge Density

The **Surface Charge Density** node provides the following surface-charge boundary condition for exterior boundaries (left) and interior boundaries (right):

$$-\mathbf{n} \cdot \mathbf{D} = \rho_s, \quad \mathbf{n} \cdot (\mathbf{D}_1 - \mathbf{D}_2) = \rho_s$$

Specify the surface charge density ρ_s at an outer boundary or at an interior boundary between two nonconducting media.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** on the **Physics** toolbar. For more information, see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

SURFACE CHARGE DENSITY

Enter the value or expression for the **Surface charge density** ρ_s (SI unit: C/m²).

External Surface Charge Accumulation

The **External Surface Charge Accumulation** node implements the boundary condition

$$-\mathbf{n} \cdot \mathbf{D} = \rho_s$$

where ρ_s is the solution of the following distributed ODE on the boundary:

$$\frac{d\rho_s}{dt} = \mathbf{n} \cdot \mathbf{J}_i + \mathbf{n} \cdot \mathbf{J}_e$$

where $\mathbf{n} \cdot \mathbf{J}_i$ is the normal component of the total ion current density on the wall and $\mathbf{n} \cdot \mathbf{J}_e$ is the normal component of the total electron current density on the wall, which are feature inputs.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Non-solid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

EXTERNAL SURFACE CHARGE ACCUMULATION

Enter values or expressions for the **Normal ion current density** $\mathbf{n} \cdot \mathbf{J}_i$ (SI unit: A/m²) and the **Normal electron current density** $\mathbf{n} \cdot \mathbf{J}_e$ (SI unit: A/m²).

Electric Displacement Field

The **Electric Displacement Field** node adds the following electric-displacement boundary condition:

$$\mathbf{n} \cdot \mathbf{D} = \mathbf{n} \cdot \mathbf{D}_0$$

It specifies the normal component of the electric displacement field at a boundary.

ELECTRIC DISPLACEMENT FIELD

Enter the coordinates of the **Boundary electric displacement field** \mathbf{D}_0 (SI unit: C/m²).

Periodic Condition

The **Periodic Condition** node defines periodicity or antiperiodicity between two boundaries. If required, activate periodic conditions on more than two boundaries, in which case the Periodic Condition tries to identify two separate surfaces that can each consist of several connected boundaries. For more complex geometries, it might be necessary to use the **Destination Selection** subnode. With this subnode the boundaries which constitute the source

and destination surfaces can be manually specified. The **Destination Selection** subnode is available from the context menu (right-click the parent node) as well as from the **Physics** toolbar, **Attributes** menu.

	When this feature is used in conjunction with a Sector Symmetry feature on connected boundaries, wherever the sector symmetry boundaries connect with the periodic boundaries, the same periodic condition feature cannot be used on both sides. At least two periodic condition features are required for the model to compute correctly.
---	---

BOUNDARY SELECTION

When using nonconforming meshes on the source and destination of a periodic boundary pair, for numerical stability, a finer mesh should be applied on the destination side. Use conforming meshes if possible.

PERIODIC CONDITION

Select a **Type of periodicity** — **Continuity** (the default), **Antiperiodicity**, or **Floquet periodicity**. Select:

- **Continuity** to make the electric potential periodic (equal on the source and destination),
- **Antiperiodicity** to make it antiperiodic, or
- **Floquet periodicity** (only available with products supporting piezoelectric modeling). Specify the components of the **k-vector for Floquet periodicity** \mathbf{k}_F (SI unit: rad/m).

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

For information about the Orientation of Source section, see [Orientation of Source and Destination](#).

Thin Low Permittivity Gap

Use the **Thin Low Permittivity Gap** node

$$\mathbf{n} \cdot \mathbf{D}_1 = \frac{\epsilon_0 \epsilon_r}{d_s} (V_1 - V_2)$$
$$\mathbf{n} \cdot \mathbf{D}_2 = \frac{\epsilon_0 \epsilon_r}{d_s} (V_2 - V_1)$$

to model a thin gap of a material with a small permittivity compared to the adjacent domains. The layer has the thickness d_s and the relative permittivity ϵ_r . The indices 1 and 2 refer to the two sides of the boundary.

THIN LOW PERMITTIVITY GAP

The default is to take the **Relative permittivity** ϵ_r (dimensionless) values **From material**. For **User defined**, enter a different value or expression. Enter a **Surface thickness** d_s (SI unit: m). The default is 5 mm.

Line Charge

For 3D components, use the **Line Charge** node to specify line charges along the edges of a geometry. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

EDGE SELECTION

Beware that constraining the potential on edges usually yields a current outflow that is mesh dependent.

LINE CHARGE

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

[Line Charge \(on Axis\)](#) and [Line Charge \(Out-of-Plane\)](#)

Line Charge (on Axis)

For 2D axisymmetric components, use the **Line Charge (on Axis)** node to specify line charges along the symmetry axis.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

LINE CHARGE (ON AXIS)

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

[Line Charge](#) and [Line Charge \(Out-of-Plane\)](#)

Line Charge (Out-of-Plane)

For 2D and 2D axisymmetric components, points are selected and this is the same as a line out-of-plane.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

Use the **Line Charge (Out-of-Plane)** node to specify line charges along the points of a geometry for 2D and 2D axisymmetric components.

POINT SELECTION

Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

LINE CHARGE (OUT-OF-PLANE)

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

[Line Charge and Line Charge \(on Axis\)](#)

Point Charge

The **Point Charge** node adds a point source to 3D components. The point charge represents an electric displacement field flowing out of the point.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

POINT SELECTION

Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CHARGE

Enter a value or expression to apply a **Point charge** Q_P (SI unit: C) to points. This source represents an electric displacement field flowing out of the point. The default is 0 C.

[Point Charge \(on Axis\) and Line Charge \(Out-of-Plane\)](#)

Point Charge (on Axis)

The **Point Charge (on Axis)** node adds a point source to 2D axisymmetric components. The point charge represents an electric displacement field flowing out of the point.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

POINT SELECTION

Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CHARGE (ON AXIS)

Enter a value or expression to apply a **Point charge** Q_P (SI unit: C) to points on an axis. This source represents an electric displacement field flowing out of the point. The default is 0 C.

[Point Charge and Line Charge \(Out-of-Plane\)](#)

Change Cross Section

This node is available with 1D components. This setting overrides the global **Cross-Section Area** setting made in any physics interface that uses this feature. For 2D components, see [Change Thickness \(Out-of-Plane\)](#).

Use the **Change Cross-Section** node to set the cross-section area for specific geometric entities.

CHANGE CROSS SECTION

Enter a value or expression for the **Cross-section area** A . The default value of 1 unit length is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 1D equation identical to the equation used for 3D components.

Change Thickness (Out-of-Plane)

This node is available for 2D components. This setting overrides the global **Thickness** setting made in any physics interface that uses this node. For 1D components, see [Change Cross Section](#).

Use the **Change Thickness (Out-of-Plane)** node to set the out-of-plane thickness for specific geometric entities.

CHANGE THICKNESS (OUT-OF-PLANE)

Enter a value or expression for the **Out-of-plane thickness** d (SI unit: m). The default value is, in most cases, 1 unit length, which is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components.

Charge Conservation, Piezoelectric

This feature is available with the Piezoelectric Devices interface, which requires the Acoustics Module, MEMS Module, or the Structural Mechanics Module. See the individual documentation for information.

The **Charge Conservation, Piezoelectric** node is normally used together with a **Piezoelectric Effect** multiphysics coupling node and a corresponding **Piezoelectric Material** node in the **Solid Mechanics** interface. The node is added

by default to the **Electrostatics** interface when adding a Piezoelectric Devices interface. It is also available from the context menu (right-click the **Electrostatics** interface parent node) or from the **Physics** toolbar.

When the **Charge Conservation, Piezoelectric** node is added to the electrostatics interface in the absence of an active **Piezoelectric Effect** multiphysics coupling node, the material behaves similarly to a **Charge Conservation** node, with electric properties corresponding to the relative permittivity entered (see below). The piezoelectric effect is *not* included in the corresponding equation system.

ELECTRIC DISPLACEMENT

If the node is used together with an active **Piezoelectric Effect** multiphysics coupling node, then these settings are locked. Note that if they are unlocked, then the material behaves like a dielectric and *not* a piezoelectric. In this case, the default is to take the **Relative permittivity** ϵ_{rS} (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** and enter values or expressions in the field or matrix.

The Electric Currents Interface

The **Electric Currents (ec)** interface (), found under the **AC/DC** branch () when adding a physics interface, is used to compute electric field, current, and potential distributions in conducting media under conditions where inductive effects are negligible; that is, when the skin depth is much larger than the studied device.

Depending on the licensed products, stationary, frequency-domain, small-signal analysis, and time-domain modeling are supported in all space dimensions. In the time and frequency domains, capacitive effects are also accounted for.

The physics interface solves a current conservation equation based on Ohm's law using the scalar electric potential as the dependent variable.

Current Conservation is the main node, which adds the equation for the electric potential and provides a Settings window for defining the electrical conductivity as well as the constitutive relation for the electric displacement field and its associated material properties, such as the relative permittivity.

When this physics interface is added, these default nodes are also added to the **Model Builder — Current Conservation**, **Electric Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and current sources. You can also right-click **Electric Currents** to select physics features from the context menu.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the name string must be unique. Only letters, numbers, and underscores (`_`) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `ec`.

PHYSICS-CONTROLLED MESH

Select the **Enable** check box to allow the physics interface to control the meshing process. Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to automatically set up an appropriate mesh sequence.

CROSS-SECTION AREA (1D)

Enter a default value for the **Cross-section area A** (SI unit: m^2). The default value of 1 is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 1D equation identical to the equation used for 3D components. See also [Change Cross Section](#) (described for the Electrostatics interface).

THICKNESS (2D)

Enter a default value for the **Out-of-plane thickness d** (SI unit: m) (see [Equation 10-1](#)). The default value of 1 m is typically not representative for a thin dielectric medium, for example. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components. See also [Change Thickness \(Out-of-Plane\)](#) (described for the Electrostatics interface).

DEPENDENT VARIABLES

The dependent variable is the **Electric potential V**. You can change its name, which changes both the field name and the variable name. If the new name coincides with the name of another electric potential field in the model, the

physics interfaces share degrees of freedom. The new name must not coincide with the name of a field of another type or with a component name belonging to some other field.

DISCRETIZATION

Domain, Boundary, Edge, Point, and Pair Nodes for the Electric Currents Interface

The Electric Currents interface has these domain, boundary, edge, point, and pair nodes available from the **Physics** ribbon toolbar (Windows users) or **Physics** context menu (Mac or Linux users). You can also right-click to access the context menu (all users).

	In general, to add a node, go to the Physics toolbar, no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the Attributes menu.
---	--

ABOUT THE BOUNDARY CONDITIONS

The exterior and interior boundary conditions listed in [Table 10-2](#) are available. The relevant physics interface condition at interfaces between different media and interior boundaries is continuity; that is,

$$\mathbf{n}_2 \cdot (\mathbf{J}_1 - \mathbf{J}_2) = 0$$

which is the natural boundary condition.

AVAILABLE NODES

These nodes are available for this physics interface, listed in alphabetical order. Also see [Table 10-2](#) for a list of interior and exterior boundary conditions, including edge, point, and pair availability.

- Boundary Current Source
- Contact Impedance
- Current Conservation
- Current Source
- Distributed Impedance
- Electric Insulation
- External Current Density
- Initial Values
- Line Current Source
- Line Current Source (on Axis)
- Normal Current Density
- Piezoresistive Material¹
- Point Current Source
- Sector Symmetry

¹This feature is available with the Piezoresistivity, Domain Currents interface, which requires the MEMS Module.

These nodes are described for the Electrostatics interface:

- [Change Cross Section](#)
- [Change Thickness \(Out-of-Plane\)](#)
- [Electric Potential](#)
- [Ground](#)
- [Periodic Condition](#)

In the *COMSOL Multiphysics Reference Manual*, see [Table 2-3](#) for links to common sections and [Table 2-4](#) for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the model that is valid on the axial symmetry boundaries only.

[Table 10-2](#) lists the interior and exterior boundary conditions available with this physics interface. It also includes edge, point, and pair availability.

TABLE 10-3: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS (INCLUDING EDGE, POINT, AND PAIR AVAILABILITY) FOR THE ELECTRIC CURRENTS INTERFACE

NODE	INTERIOR	EXTERIOR	ALSO AVAILABLE FOR
Boundary Current Source	x		pairs
Contact Impedance	x		pairs
Distributed Impedance	x	x	not applicable
Electric Insulation	x	x	pairs
Electric Potential	x	x	edges, points, and pairs
Ground	x	x	edges, points, and pairs
Normal Current Density		x	not applicable
Periodic Condition		x	not applicable

Current Conservation

The **Current Conservation** node adds the continuity equation for the electrical potential and provides an interface for defining the electric conductivity as well as the constitutive relation and the relative permittivity for the displacement current.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Non-solid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

CONDUCTION CURRENT

By default, the **Electrical conductivity** σ (SI unit: S/m) for the media is defined **From material**. Or select **User defined** or **Linearized resistivity**.

User Defined

For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** depending on the characteristics of the electrical conductivity, and then enter values or expressions for the electrical conductivity σ in the field or matrix. The default is 0 S/m. If type of temperature dependence is used other than a linear temperature relation, enter any expression for the conductivity as a function of temperature.

Linearized Resistivity

Select **Linearized resistivity** for a temperature-dependent conductivity (this occurs in, for example, Joule heating, and is also called resistive heating). The equation describing the conductivity:

$$\sigma = \frac{1}{\rho_0(1 + \alpha(T - T_{\text{ref}}))}$$

where ρ_0 is the resistivity at the reference temperature T_{ref} , and α is the temperature coefficient of resistance, which describes how the resistivity varies with temperature.

The default **Reference resistivity** ρ_0 (SI unit: $\Omega \cdot \text{m}$), **Reference temperature** T_{ref} (SI unit: K), and **Resistivity temperature coefficient** α (SI unit: $1/\text{K}$) are taken **From material**, which means that the values are taken from the domain (or boundary) material. T is the current temperature, which can be a value that is specified as a model input or the temperature from a heat transfer interface. The definition of the temperature field is in the **Model Inputs** section.

To specify other values for any of these properties, select **User defined** from the list and then enter a value or expression for each. The default values are:

- 1 $\Omega \cdot \text{m}$ for the Reference resistivity
- 273.15 K for the Reference temperature, and
- 0 $1/\text{K}$ for the Resistivity temperature coefficient

ELECTRIC FIELD

Select a **Constitutive relation** to describe the macroscopic properties of the medium (relating the electric displacement **D** with the electric field **E**) and the applicable material properties, such as the relative permittivity. For a description of the constitutive relations **Relative permittivity**, **Polarization**, and **Remanent electric displacement**, see **Electric Field** as described for the **Charge Conservation** node for the Electrostatics interface. The constitutive relations specific to Electric Currents are:

- **Dielectric losses**: uses the constitutive relation $\mathbf{D} = \epsilon_0(\epsilon' + \epsilon'')\mathbf{E}$. Specify that the **Relative permittivity (real part)** ϵ' (dimensionless) and the **Relative permittivity (imaginary part)** ϵ'' (dimensionless) must be taken **From material** or be **User defined**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** and enter values or expressions in the field or matrix. The default is 1.
- **Loss tangent, loss angle**: uses the constitutive relation $\mathbf{D} = \epsilon_0\epsilon'(1+j\tan\delta)\mathbf{E}$. Specify the **Relative permittivity (real part)** ϵ' (dimensionless) and **Loss angle** δ (SI unit: rad).
- **Loss tangent, dissipation factor**: uses the constitutive relation $\mathbf{D} = \epsilon_0\epsilon'(1+j\tan\delta)\mathbf{E}$. Specify the **Relative permittivity (real part)** ϵ' (dimensionless) and the **Dissipation factor** $\tan\delta$ (dimensionless).

Initial Values

The **Initial Values** node adds an initial value for the electric potential that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear solver. If more than one set of initial values is required,

from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and current sources. Add more **Initial Values** nodes from the **Physics** toolbar.

INITIAL VALUES

Enter a value or expression for the initial value of the **Electric potential** V (SI unit: V). The default value is 0 V.

External Current Density

The **External Current Density** node adds an externally generated current density \mathbf{J}_e , which appears in Ohm's law

$$\mathbf{J} = \sigma \mathbf{E} + \mathbf{J}_e$$

and in the equation that the physics interface defines.

The external current density does not contribute to the losses (due to Joule heating), since there is no electric field associated with it. To include the contribution to the losses from the external current density, select the **Add contribution of the external current density to the losses** check box. Then select an option from the **External losses** list—**From domain conductivity** (the default) or **User defined**. If **From domain conductivity** is selected, the heat source is computed using the conductivity specified in the material model feature (such as **Current Conservation**) that is applied in the domain. For **User defined**, enter a value for Q_e (SI unit: W/m³) to specify a user-defined heat source.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

EXTERNAL CURRENT DENSITY

Based on space dimension, enter the coordinates (**x**, **y**, and **z** for 3D components, for example) of the **External current density** \mathbf{J}_e (SI unit: A/m²). The defaults are 0 A/m².

Current Source

The **Current Source** node adds a distributed current source Q_j in the equation that the physics interface defines. Use this node with caution as it can violate the current conservation law that is inherent in Maxwell-Ampère's law.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

CURRENT SOURCE

Enter a value or expression for the **Current source** Q_j (SI unit: A/m³). The default is 0 A/m³.

Electric Insulation

The **Electric Insulation** node, which is the default boundary condition, adds electric insulation as the boundary condition:

$$\mathbf{n} \cdot \mathbf{J} = 0$$

This boundary condition means that no electric current flows into the boundary. At interior boundaries, it means that no current can flow through the boundary and that the electric potential is discontinuous across the boundary. It is also applicable at symmetric boundaries where the potential is known to be symmetric with respect to the boundary.

Electric insulation as the default boundary condition is not applicable to interior boundaries. To add electric insulation to an interior boundary, add an **Electric Insulation** node in addition to the one that represents the default boundary condition.

Boundary Current Source

The **Boundary Current Source** node adds a current source Q_j on the boundary.

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = Q_j$$

It is applicable to interior boundaries that represent either a source or a sink of current. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

BOUNDARY CURRENT SOURCE

Enter a value or expression for the **Boundary current source** Q_j (SI unit: A/m²). The default is 0 A/m².

Normal Current Density

The **Normal Current Density** node is applicable to exterior boundaries that represent either a source or a sink of current. It provides a condition for specifying the normal current density as an inward or outward current flow:

$$-\mathbf{n} \cdot \mathbf{J} = J_n$$

Or alternatively, as a current density \mathbf{J}_0 :

$$\mathbf{n} \cdot \mathbf{J} = \mathbf{n} \cdot \mathbf{J}_0$$

The normal current density is positive when the current flows inward in the domain. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

NORMAL CURRENT DENSITY

Select a **Type**—**Inward current density** (the default) or **Current density**.

- For **Inward current density** enter a value or expression for the **Normal current density** J_n (SI unit: A/m²). Use a positive value for an inward current flow or a negative value for an outward current flow. The default is 0 A/m².
- For **Current density** enter values or expressions for the components of the **Current density** \mathbf{J}_0 (SI unit: A/m²). The defaults are 0 A/m².

Distributed Impedance

The **Distributed Impedance** node adds a distributed impedance boundary condition to a model.

The **Harmonic Perturbation** subnode (it is of the exclusive type) is available from the context menu (right-click the parent node) or on the **Physics** toolbar, click the **Attributes** menu and select **Harmonic Perturbation**. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

Use this boundary condition to model a thin sheet of a resistive material connected to a reference potential V_{ref} .

The layer impedance can be specified either with the bulk material conductivity σ_s , the relative permittivity ϵ_r and layer thickness d_s , or directly with the surface resistance ρ_s and capacitance C_s . Assuming DC currents, the equation is:

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = \frac{\sigma_s}{d_s}(V - V_{\text{ref}})$$

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = \frac{1}{\rho_s}(V - V_{\text{ref}})$$

DISTRIBUTED IMPEDANCE

Enter the reference potential V_{ref} (SI unit: V). The default is 0 V.

Select a potentially complex-valued **Layer specification**—**Thin layer** (the default) or **Surface impedance**.

- For **Thin layer**, enter values or expressions for the:
 - **Surface thickness** d_s (SI unit: m). The default is $5 \cdot 10^{-3}$ m (5 mm).
 - **Electrical conductivity** σ (SI unit: S/m) and **Relative permittivity** ϵ_r (dimensionless). The defaults take values **From material**. For **User defined**, enter different values or expressions. The default electrical conductivity is $1 \cdot 10^{-2}$ S/m and the default relative permittivity is 1.
- For **Surface impedance**, enter values or expressions for the **Surface resistance** ρ_s (SI unit: $\Omega \cdot \text{m}^2$) and the **Surface capacitance** C_s (SI unit: F/m²). The default surface impedance is $1 \cdot 10^{-8} \Omega \cdot \text{m}^2$ and the default surface capacitance is 0 F/m².

Contact Impedance

Use the **Contact Impedance** node on interior boundaries to model a thin layer of resistive material. It can also be added as a pair using a **Pair Contact Impedance** node. The feature allows specifying the contact impedance either by entering the properties of the material together with the layer thickness, or by entering the impedance properties of the thin layer directly.

The feature applies the following conditions that relate the normal electric current density with the jump in the electric potential:

$$\mathbf{n} \cdot \mathbf{J}_1 = \frac{\sigma}{d_s} (V_1 - V_2)$$

$$\mathbf{n} \cdot \mathbf{J}_2 = \frac{\sigma}{d_s} (V_2 - V_1)$$

$$\mathbf{n} \cdot \mathbf{J}_1 = \frac{1}{\rho_s} (V_1 - V_2)$$

$$\mathbf{n} \cdot \mathbf{J}_2 = \frac{1}{\rho_s} (V_2 - V_1)$$

The first two equations refer to a layer impedance specified using the bulk material conductivity σ_s and the layer thickness d_s , while the last two equations refer to the case in which the surface resistance ρ_s is specified. The indices 1 and 2 refer to the two sides of the boundary. These parameters work the same as with [Distributed Impedance](#).

CONTACT IMPEDANCE

Select a potentially complex-valued **Layer specification**—**Thin layer** (the default) or **Surface impedance**.

- For **Thin layer**, enter values or expressions for the:
 - **Surface thickness** d_s (SI unit: m). The default is $5 \cdot 10^{-3}$ m (5 mm).
 - **Electrical conductivity** σ (SI unit: S/m) and **Relative permittivity** ϵ_r (dimensionless). The defaults take values **From material**. For **User defined**, enter different values or expressions. The default electrical conductivity is $1 \cdot 10^{-2}$ S/m and the default relative permittivity is 1.
- For **Surface impedance**, enter values or expressions for the **Surface resistance** ρ_s (SI unit: $\Omega \cdot m^2$) and the **Surface capacitance** C_s (SI unit: F/m 2). The default surface impedance is $1 \cdot 10^{-8} \Omega \cdot m^2$ and the default surface capacitance is 0 F/m 2 .

Thin-Film Resistance: Application Library path **COMSOL_Multiphysics/ Electromagnetics/thin_film_resistance**

Sector Symmetry

Select **Sector Symmetry** at interfaces between rotating objects where sector symmetry is used. It is only available for pairs. A default subnode is added. Right-click to select additional features from the **Fallback Features** submenu. In 2D, this feature assumes rotation around the origin.

This feature is always used in conjunction with a **Periodic Condition** on adjacent radial sector boundaries. Note that the same periodic condition feature cannot be used on both sides of where the sector symmetry boundaries connect with the periodic boundaries. At least two periodic condition features are required for the model to compute correctly.

PAIR SELECTION

When using nonconforming meshes on the source and destination of a pair, for numerical stability, a finer mesh should be applied on the destination side for any pair with a condition that imposes a coupling or a constraint across the pair. The sector symmetry feature falls into this category.

SECTOR SETTINGS

Enter the **Number of sectors (<50)** n_{sect} . The default is 2.

Select a **Type of periodicity** — **Continuity** (the default) or **Antiperiodicity**.

Based on space dimension, enter values or expressions in the table for the **Axis of rotation** a_{rot} .

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Line Current Source

The **Line Current Source** node adds a line source to edges in 3D components and to points in 2D and 2D axisymmetric components. The line source represents electric current per unit length.

EDGE OR POINT SELECTION

Beware that constraining the potential on edges or points usually yields a current outflow that is mesh dependent.

LINE CURRENT SOURCE

Enter a value or expression to apply a **Line current source** Q_j (SI unit: A/m). This source represents electric current per unit length. The default is 0 A/m.

[Line Current Source \(on Axis\)](#) for 2D axisymmetric components.

Line Current Source (on Axis)

The **Line Current Source (on Axis)** node adds a line source to boundaries in 2D axisymmetric components. The line source represents electric current per unit length.

LINE CURRENT SOURCE (ON AXIS)

Enter a value or expression to apply a **Line current source** Q_j (SI unit: A/m) to boundaries. This source represents electric current per unit length.

[Line Current Source](#)

Point Current Source

The **Point Current Source** node adds a point source and represents an electric current flowing out of the point. Add point sources to 3D components from the **Points** menu. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

POINT SELECTION

Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CURRENT SOURCE

Enter a value or expression to apply a **Point current source** Q_j (SI unit: A) to points. This source represents an electric current flowing out of the point.

- [Line Current Source](#) for 2D components
- [Point Current Source \(on Axis\)](#) for 2D axisymmetric components

Point Current Source (on Axis)

The **Point Current Source (on Axis)** node adds a point source and represents an electric current flowing out of the point in 2D axisymmetric components.

POINT SELECTION

Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CURRENT SOURCE

Enter a value or expression to apply a **Point current source** Q_j (SI unit: A) to points. This source represents an electric current flowing out of the point.

-

Piezoresistive Material

The **Piezoresistive Material** is normally used together with a **Piezoresistive Effect, Domain Currents** multiphysics coupling node. The node is added by default to the **Electric Currents** interface when adding a **Piezoresistivity, Domain Currents** predefined multiphysics coupling interface. It is also available from the context menu (right-click the **Electric Currents** interface parent node) or from the **Physics** toolbar.

When the **Piezoresistive Material** node is added to the Electric Currents interface in the absence of an active **Piezoelectric Effect, Domain Currents** multiphysics coupling node, the material behaves similarly to a **Current Conservation** node, with electric properties corresponding to the relative permittivity and electrical conductivity entered. The piezoresistive effect is *not* included in the corresponding equation system.

PIEZORESISTIVE MATERIAL PROPERTY

This node should be used together with an active **Piezoresistive Effect, Domain Currents** multiphysics coupling node. Select a **Constitutive model — Piezoresistance form** or **Elastoresistance form**. For each of the following, the default uses values **From material**. For **User defined** enter other values in the matrix or field.

- Specify a **Electrical conductivity, zero stress** (SI unit: S/m). This typically comes from the material added under the Materials node.
- For **Piezoresistance form**, select a **Piezoresistance coupling matrix** Π_l (SI unit: $\text{m}^4/(\text{s}\cdot\text{A}^2)$); note that this is equivalent to $\Omega\cdot\text{m}/\text{Pa}$.
- For a **Elastoresistance form**, select an **Elastoresistance coupling matrix** M_l (SI unit: $\Omega\cdot\text{m}$).

The Magnetic Fields Interface

The **Magnetic Fields (mf)** interface (), found under the **AC/DC** branch () when adding a physics interface, is used to compute magnetic field and induced current distributions in and around coils, conductors, and magnets. Depending on the licensed products, stationary, frequency-domain, small-signal analysis, and time-domain modeling are supported in 2D and 3D. Note that the frequency and time domain formulations become ill-posed when approaching the static limit. One may extend the useful frequency range downward by adding a low conductivity.

The physics interface solves Maxwell's equations, which are formulated using the magnetic vector potential and, optionally for coils, the scalar electric potential as the dependent variables.

The main node is Ampère's Law, which adds the equation for the magnetic vector potential and provides an interface for defining the constitutive relations and its associated properties, such as the relative permeability.

When this physics interface is added, these default nodes are also added to the **Model Builder — Magnetic Fields**, **Ampère's Law**, **Magnetic Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement boundary conditions and external currents. You can also right-click **Magnetic Fields** to select physics features from the context menu.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the name string must be unique. Only letters, numbers, and underscores (`_`) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `mf`.

BACKGROUND FIELD

This section allows the specification of a background magnetic vector potential (that generates a background magnetic flux density). The only option to **Solve for** is **Full field**.

COMPONENTS

The current vector has the same direction as the magnetic vector potential. This setting also controls the direction in which applied and induced currents can flow in the model. The default option is to solve for the out-of-plane component only. Therefore, the only **Components** option is **Out-of-plane vector potential**.

THICKNESS

For 2D components, enter a value or expression for the global **Out-of-plane thickness d** (SI unit: m). The default of 1 m is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components.

Use the [Change Thickness \(Out-of-Plane\)](#) node (described for the Electrostatics interface) to define specific geometric entities (for example, domains) instead of a global setting for the thickness.

ERROR CHECK

To display this section, click the **Show** button () and select **Advanced Physics Options**.

When the **Check applicability of features in study** check box is selected, any features that are incompatible with the study will generate an error message when trying to solve or show the default solver. No solver will be generated.

Deselect it and you will be able to run the model, possibly with runtime errors instead. It is available to allow the advanced user to tweak any feature and use it outside of its intended study scope.

PHYSICS-CONTROLLED MESH

Select the **Enable** check box to allow the physics interface to control the meshing process. Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to automatically set up an appropriate mesh sequence.

DEPENDENT VARIABLES

The dependent variable is the **Magnetic vector potential A**. You can change both its field name and the individual component variable names. If the new field name coincides with the name of another magnetic vector potential field in the model, the physics interfaces share degrees of freedom and component names. The new field name must not coincide with the name of a field of another type, or with a component name belonging to some other field. Component names must be unique within a model, except for fields of the same type sharing a common field name.

DISCRETIZATION

To display all settings available in this section, click the **Show** button () and select **Advanced Physics Options**

	<ul style="list-style-type: none">• Domain, Boundary, Point, and Pair Nodes for the Magnetic Fields Interface• Theory of Magnetic Fields
	<i>Quadrupole Lens:</i> Application Library path COMSOL_Multiphysics/Electromagnetics/quadrupole

Domain, Boundary, Point, and Pair Nodes for the Magnetic Fields Interface

The Magnetic Fields interface has these domain, boundary, point, and pair nodes available, which are listed in alphabetical order.

About the Boundary Conditions

With no surface currents present, the physics interface conditions

$$\begin{aligned}\mathbf{n}_2 \times (\mathbf{A}_1 - \mathbf{A}_2) &= \mathbf{0} \\ \mathbf{n}_2 \times (\mathbf{H}_1 - \mathbf{H}_2) &= \mathbf{0}\end{aligned}$$

need to be fulfilled. Because **A** is being solved for, the tangential component of the magnetic potential is always continuous, and thus the first condition is automatically fulfilled. The second condition is equivalent to the natural boundary condition and is hence also fulfilled unless surface currents are explicitly introduced.

Table 10-2 lists the interior and exterior boundary conditions available with this physics interface.

TABLE 10-4: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS FOR THE MAGNETIC FIELDS INTERFACE

NODE	INTERIOR	EXTERIOR
Magnetic Field		x
Magnetic Insulation	x	x
Magnetic Potential	x	x
Perfect Magnetic Conductor	x	x

TABLE 10-4: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS FOR THE MAGNETIC FIELDS INTERFACE

NODE	INTERIOR	EXTERIOR
Periodic Condition		x
Surface Current Density	x	x

Available Nodes

These nodes, listed in alphabetical order, are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or by right-clicking to access the context menu (all users).

	In general, to add a node, go to the Physics toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the Attributes menu.
--	---

--	--

Ampère's Law

The **Ampère's Law** node adds Ampère's law for the magnetic field and provides an interface for defining the constitutive relation and its associated properties as well as electric properties.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Non-solid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for

which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

CONDUCTION CURRENT

This section is described for the [Current Conservation](#) feature.

ELECTRIC FIELD

The default **Relative permittivity** ϵ_r (dimensionless) for the media is used **From material** and defined on the shell domain. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** based on the characteristics of the permittivity and then enter values or expressions in the field or matrix.

MAGNETIC FIELD

Specify the constitutive relation that describes the macroscopic properties of the medium (relating the magnetic flux density \mathbf{B} and the magnetic field \mathbf{H}) and the applicable material properties, such as the relative permeability.

The equation for the selected constitutive relation displays under the list. For all options, the default uses values **From material**, or select **User defined** to enter a different value or expression.

Select a **Constitutive relation — Relative permeability** (the default), **H-B curve**, **Magnetic losses**, **Remanent flux density**, **Magnetization**, or **Effective H-B curve**.

Relative Permeability

Select **Relative permeability** μ_r (dimensionless) to use the constitutive relation $\mathbf{B} = \mu_0 \mu_r \mathbf{H}$. For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** and enter values or expressions in the field or matrix.

H-B Curve

Select **H-B curve** $|\mathbf{H}|$ (SI unit: A/m) to use a curve that relates magnetic flux density \mathbf{B} and the magnetic field \mathbf{H} as $|\mathbf{H}| = f(|\mathbf{B}|)$.

The **Magnetic field norm** setting can take the values **From material**, **External**, or **User defined**.

When **External** is selected, specify the **External material** to use (from the **Materials** node under **Global Definitions**). This setting allows using material models or constitutive relations defined in an external library. See [Working with External Materials](#) for more information.

When **User defined** is selected, specify a user-defined expression for the magnetic field norm. The direction of the magnetic field is taken to be the same as the direction of the magnetic flux density at each point.

Magnetic Losses

Select **Magnetic losses** μ' and μ'' (dimensionless) to describe the relative permeability as a complex-valued quantity: $\mu_r = \mu' + i\mu''$, where μ' and μ'' are the real and imaginary parts, respectively.

Remanent Flux Density

Select **Remanent flux density** \mathbf{B}_r (SI unit: T) to use the constitutive relation $\mathbf{B} = \mu_0 \mu_r \mathbf{H} + \mathbf{B}_r$, where \mathbf{B}_r is the remanent flux density (the flux density when no magnetic field is present).

- The default relative permeability μ_r (dimensionless) uses values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** based on the characteristics of the relative permeability and enter another value or expression in the field or matrix.
- Enter **x** and **y** components for the **Remanent flux density** \mathbf{B}_r .

Magnetization

Select **Magnetization** \mathbf{M} (SI unit: A/m) to use the constitutive relation $\mathbf{B} = \mu_0 \mathbf{H} + \mu_0 \mathbf{M}$. Enter **x** and **y** components.

Effective B-H Curve

Select **Effective B-H curve** $|\mathbf{H}|_{\text{eff}}$ (SI unit: A/m) to use an effective curve that provides the local linearized relation

Ampère's Law, Magnetostrictive

The **Ampère's Law, Magnetostrictive** node adds Ampère's law for the magnetic field in a magnetostrictive material and provides an interface for defining the electric properties. It is normally used as part of **Magnetostriction** multiphysics interface together with a **Magnetostriction** multiphysics coupling node and **Magnetostrictive Material** node in the corresponding **Solid Mechanics** interface. **Ampère's Law, Magnetostrictive** node is added by default to the **Magnetic Fields** interface when adding a Magnetostriction multiphysics interface. The interface requires the AC/DC Module and at least one of the following modules: Structural Mechanics, MEMS, Acoustics.

When the **Ampère's Law, Magnetostrictive** node is added to the Magnetic Fields interface in the absence of an active **Magnetostriction** multiphysics coupling node, the material behaves similarly to an **Ampère's Law** node with some limitations. Thus, the magnetic permittivity of free space will be assumed. The magnetostrictive effect is then *not* included in the corresponding equation system.

CONDUCTION CURRENT

This section is described for the [Current Conservation](#) feature.

ELECTRIC FIELD

The default **Relative permittivity** ϵ_r (dimensionless) for the media is used **From material** and defined on the shell domain. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Anisotropic** based on the characteristics of the permittivity and then enter values or expressions in the field or matrix.

MAGNETIC FIELD

Specify the constitutive relation that describes the macroscopic properties of the medium (relating the magnetic flux density \mathbf{B} and the magnetic field \mathbf{H}) for a magnetostrictive material:

$$\mathbf{B} = \mu_0[\mathbf{H} + \mathbf{M}(\mathbf{H}, S_{\text{mech}}) + \mathbf{M}_r]$$

where $\mathbf{M}(\mathbf{H}, S_{\text{mech}})$ is material magnetization which depends on the magnetic field and mechanical stress; a particular form of this dependency can be specified under the corresponding **Magnetostrictive Material** node in the **Solid Mechanics** interface.

\mathbf{M}_r is the remanent magnetization (SI unit: A/m). Enter **X** and **Y** components.

- [Magnetostriction](#)
- [Modeling Magnetostrictive Materials](#)
- [Magnetostrictive Material](#)

Initial Values

The **Initial Values** node adds an initial value for the magnetic vector potential \mathbf{A} that can serve as an initial value for a transient simulation or as an initial guess for a nonlinear solver.

INITIAL VALUES

Enter values or expressions for the **Magnetic vector potential** \mathbf{A} (SI unit: Wb/m). The defaults are 0 Wb/m.

External Current Density

The **External Current Density** node adds an externally generated current density \mathbf{J}_e , which appears on the right-hand side of the equation that the Magnetic Fields interface defines.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

EXTERNAL CURRENT DENSITY

Enter a value or expression for each component of the **External current density** \mathbf{J}_e (SI unit: A/m²). The defaults are 0 A/m².

The external current density does not contribute to the losses (due to Joule heating), since there is no electric field associated with it. To include the contribution to the losses from the external current density, select the **Add contribution of the external current density to the losses** check box. Then select an option from the **External losses** list—**From domain conductivity** (the default) or **User defined**. If **From domain conductivity** is selected, the heat source is computed using the conductivity specified in the material model feature (such as **Ampère's Law**) that is applied in the domain. For **User defined**, enter a value for Q_e (SI unit: W/m³) to specify a user-defined heat source.

Velocity (Lorentz Term)

This node is only valid in 2D and 2D axisymmetry when only solving for the out-of-plane component of the magnetic vector potential.

Correct use of the velocity feature requires deep physical insight. In situations when the moving domain is of bounded extent in the direction of the motion, material properties vary in this direction, or the domains contains magnetic sources that also move, the Lorentz term must not be used.

The **Velocity (Lorentz term)** node adds velocity \mathbf{v} . The external current is equal to $\sigma\mathbf{v} \times \mathbf{B}$.

An operational definition of when it can be used is that the moving domain should only contain an induced magnetic source (magnetization plus eddy currents) that has to be stationary with respect to the motion. Thus, it cannot be used for modeling projectiles of finite length or projectiles containing magnets. It can be used to model conductive, homogeneous spinning disks (magnetic brakes); magnets over a moving infinite homogeneous plane (maglev trains); and flow of homogeneous conducting fluid past a magnet (liquid metal pumps or Hall generators/thrusters, for example).

If you are not sure how to proceed, contact the COMSOL Support Center: <http://www.comsol.com/support>.

VELOCITY (LORENTZ TERM)

User defined is selected by default. Enter the components for the **Velocity** vector \mathbf{v} (SI unit: m/s) or, if present, select any velocity field defined in the model. For example, using the velocity field is useful when coupling to the velocity field of a fluid for a magnetohydrodynamic model.

Magnetic Insulation

The **Magnetic Insulation** node is the default boundary condition for the Magnetic Fields interface and adds a boundary condition that sets the tangential components of the magnetic potential to zero at the boundary $\mathbf{n} \times \mathbf{A} = 0$.

Magnetic insulation is a special case of the magnetic potential boundary condition that sets the tangential component of the magnetic potential to zero.

This node is used for the modeling of a lossless metallic surface, for example, a ground plane or as a symmetry type boundary condition. The node imposes symmetry for magnetic fields and “magnetic currents.” In the transient and time harmonic formulations, it also imposes antisymmetry for electric fields and electric currents. The node supports induced electric surface currents and thus any prescribed or induced electric currents (volume, surface, or edge currents) flowing into a perfect electric conductor boundary are automatically balanced by induced surface currents.

The Magnetic Insulation node can also be applied on interior boundaries. The boundary will then support two surface current densities on the two sides, denoted bu \mathbf{J}_{su} (upside) and \mathbf{J}_{sd} (downside).

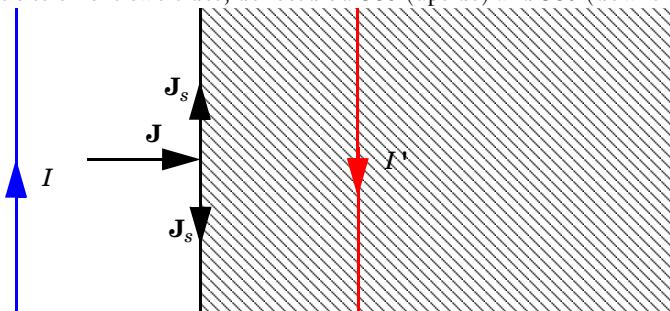

Figure 10-1: The magnetic insulation boundary condition is used on exterior and interior boundaries representing the surface of a lossless metallic conductor or (on exterior boundaries) a symmetry cut. The shaded (metallic) region is not part of the model but still carries effective mirror images of the sources. Note also that any current flowing into the boundary is perfectly balanced by induced surface currents. The tangential vector potential (and electric field) vanishes at the boundary.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Weak constraints perform poorly when applied on vector elements. They should be used when the magnetic vector potential is discretized with Lagrange elements, for example, when solving for out-of-plane component in a two-dimensional component.

Magnetic Field

The **Magnetic Field** node adds a boundary condition for specifying the tangential component of the magnetic field at the boundary:

$$\mathbf{n} \times \mathbf{H} = \mathbf{n} \times \mathbf{H}_0$$

The **Harmonic Perturbation** subnode (it is of the exclusive type) is available from the context menu (right-click the parent node) or on the **Physics** toolbar by clicking the **Attributes** menu and selecting **Harmonic Perturbation**. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

MAGNETIC FIELD

Enter the value or expression for the **Magnetic Field** \mathbf{H}_0 (SI unit: A/m) vector coordinates. The defaults are 0 A/m.

Surface Current Density

The **Surface Current** node adds a boundary condition for a surface current density \mathbf{J}_s :

$$\begin{aligned}-\mathbf{n} \times \mathbf{H} &= \mathbf{J}_s \\ \mathbf{n} \times (\mathbf{H}_1 - \mathbf{H}_2) &= \mathbf{J}_s\end{aligned}$$

These expressions apply to exterior and interior boundaries respectively. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** on the **Physics** toolbar. For more information see [Harmonic Perturbation — Exclusive and Contributing Nodes](#).

SURFACE CURRENT

Enter values or expressions for the **Surface current density** \mathbf{J}_{s0} (SI unit: A/m) coordinates. The defaults are 0 A/m.

Magnetic Potential

The **Magnetic Potential** node adds a boundary condition for the magnetic vector potential:

$$\mathbf{n} \times \mathbf{A} = \mathbf{n} \times \mathbf{A}_0$$

MAGNETIC POTENTIAL

Enter a value or expression for the **Magnetic vector potential** \mathbf{A}_0 (SI unit: Wb/m) coordinates.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Perfect Magnetic Conductor

The **Perfect Magnetic Conductor** boundary condition $\mathbf{n} \times \mathbf{H} = 0$ is a special case of the surface current boundary condition that sets the tangential component of the magnetic field and thus also the surface current density to zero. On external boundaries, this can be interpreted as a “high surface impedance” boundary condition or used as a symmetry type boundary condition. It imposes symmetry for electric fields and electric currents. Electric currents (volume, surface, or edge currents) are not allowed to flow into a perfect magnetic conductor boundary as that would violate current conservation. On interior boundaries, the perfect magnetic conductor boundary condition literally sets the tangential magnetic field to zero, which, in addition to setting the surface current density to zero, also makes the tangential magnetic vector potential (and in dynamics the tangential electric field) discontinuous.

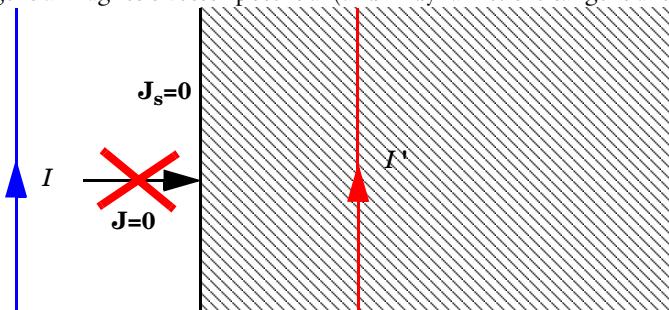

Figure 10-2: The perfect magnetic conductor boundary condition is used on exterior boundaries representing the surface of a high impedance region or a symmetry cut. The shaded (high impedance) region is not part of the model but nevertheless carries effective mirror images of the sources. Note also that any electric current flowing into the boundary

is forbidden as it cannot be balanced by induced electric surface currents. The tangential magnetic field vanishes at the boundary.

Line Current (Out-of-Plane)

Use the **Line Current (Out-of-Plane)** node, selected from the **Points** menu, to specify a line current out of the modeling plane. In axially symmetric geometries this is the rotational (azimuthal) direction; in 2D geometries this is the z-direction.

LINE CURRENT (OUT-OF-PLANE)

Enter a value or expression for the **Out-of-plane current** I_0 (SI unit: A).

Line Current (on Axis)

The **Line Current (on Axis)** feature is available for 2D axisymmetric components. It applies to edges that coincide with the symmetry axis, and is active only when in-plane magnetic vector potential components are available (for more information, see [Components](#)). Use the **Line Current (on Axis)** feature to specify a line current along the symmetry axis.

LINE CURRENT (ON AXIS)

Enter a value or expression for the **Line current in z-direction** I_z (SI unit: A).

The Pressure Acoustics Interface

This chapter describes how to use the Pressure Acoustics, Frequency Domain interface, found under the **Acoustics>Pressure Acoustics** branch () when adding a physics interface.

Fundamentals of Acoustics

This section includes a brief introduction to acoustics, gives some examples of standard acoustics problems, and provides a short introduction to the mathematical formulation of the governing equations.

In this section:

- [Acoustics Explained](#)
- [Examples of Standard Acoustics Problems](#)
- [Different Acoustic Interfaces](#)
- [Mathematical Models for Acoustic Analysis](#)

Acoustics Explained

Acoustics is the physics of sound. Sound is the sensation, as detected by the ear, of very small rapid changes in the air pressure above and below a static value. This static value is the atmospheric pressure (about 100,000 pascals), which varies slowly. A sound pressure wave is associated with a flow of energy—the intensity. Physically, sound in air is a longitudinal wave where the wave motion is in the direction of the movement of energy. The wave crests are the pressure maxima, while the troughs represent the pressure minima.

Sound results when the air is disturbed by some source. An example is a vibrating object, such as a speaker cone in a sound system. It is possible to see the movement of a bass speaker cone when it generates sound at a very low frequency. As the cone moves forward it compresses the air in front of it, causing an increase in air pressure. Then it moves back past its resting position and causes a reduction in air pressure. This process continues, radiating a wave of alternating high and low pressure propagating at the speed of sound.

The propagation of sound in solids happens through small-amplitude elastic oscillations of its shape. These elastic waves are transmitted to surrounding fluids as ordinary sound waves. The elastic sound waves in the solid are the counterpart to the pressure waves or compressible waves propagating in the fluid.

Examples of Standard Acoustics Problems

These standard problems or scenarios occur frequently when analyzing acoustics:

THE RADIATION PROBLEM

A vibrating structure (a speaker, for example) radiates sound into the surrounding space. A radiation boundary condition or perfectly matched layer (PML) is necessary to model the unbounded open domain.

THE SCATTERING PROBLEM

An incident wave impinges on a body and creates a scattered wave. A radiation boundary condition or PML is necessary. This could be a sonar application in underwater acoustics or an analysis of the scattered sound field around a human head.

THE SOUND FIELD IN AN INTERIOR SPACE

The acoustic waves stay in a finite volume so no radiation condition is necessary. For example, this case represents the sound inside a room or a car interior. A more advanced example is the sound inside a transducer like a microphone; in this case, the acoustic field should be solved with the Thermoviscous Acoustics interface. Analysis using thermoviscous acoustics requires the Acoustics Module.

COUPLED FLUID-ELASTIC STRUCTURE INTERACTION (STRUCTURAL ACOUSTICS)

If the radiating or scattering structure consists of an elastic material, the interaction must be considered between the body and the surrounding fluid. In the multiphysics coupling, the acoustic analysis provides a load (the sound pressure) to the structural analysis, and the structural analysis provides accelerations to the acoustic analysis.

THE TRANSMISSION PROBLEM

An incident sound wave propagates into a body, which can have different acoustic properties. Pressure and acceleration are continuous on the boundary. A typical transmission problem is that of modeling the behavior of mufflers.

AEROACOUSTICS PROBLEMS

The sound (noise) field is influenced by a background flow. This could be the propagating sound from a jet engine or the acoustic damping properties of a muffler with flow. Analysis of these types of problems requires the addition of the Acoustics Module.

POROELASTIC WAVES PROBLEM

If the acoustic waves are propagating inside the saturating fluid of porous material, the detailed coupling between the fluid pressure and the solid displacement needs to be taken into account. In cases when only the fluid pressure is of interest, the porous material can be modeled using an equivalent fluid model. Analysis of this type of problem requires the addition of the Acoustics Module.

TRANSDUCER PROBLEMS

Transducers are devices for transformation of one form of energy to another (electrical, mechanical, or acoustical). This type of problem is common in acoustics and is a true multiphysics problem involving electric, structural, and acoustic interfaces. Typical problems of this type involve modeling loudspeakers, microphones, and piezo transducers. Analysis of these types of problems requires the addition of the Acoustics Module.

Different Acoustic Interfaces

Depending on the basic dependent variable used to model the acoustic field, the acoustical interfaces can be divided into the following main categories.

- Pressure acoustics—The dependent variable is the acoustic pressure p .
- Acoustic-solid interaction—The dependent variables are the pressure p and the displacement field \mathbf{u} in the solid. This type of problem requires the addition of the Acoustics Module.
- Poroelastic waves—The dependent variables are the pressure p inside the saturating fluid and the total displacement \mathbf{u} of the porous matrix. This type of problem requires the addition of the Acoustics Module.
- Aeroacoustics—The dependent variables are the acoustic perturbations to the background mean flow fields. In the Linearized Potential Flow interface, it is the potential ϕ for the acoustic particle-velocity field $\mathbf{v} = \nabla\phi$. In the Linearized Euler interface, the dependent variables are the acoustic variations in pressure p , density ρ , and velocity field \mathbf{u} . In the linearized Navier-Stokes, they are the pressure p , velocity field \mathbf{u} , and temperature T . In the typical situation, the background fluid is in motion with, for example, a total velocity $\mathbf{u}_{tot} = \mathbf{u}_0 + \mathbf{u}$, split into a stationary background-flow velocity \mathbf{u}_0 and the particle velocity \mathbf{u} associated with the acoustic waves. This type of problem requires the addition of the Acoustics Module.
- Thermoviscous acoustics—The dependent variables are the acoustic pressure p , the particle-velocity field \mathbf{v} , and the acoustic temperature variation T . This is a detailed acoustic model solving the full set of linearized equations for a compressible flow: Navier-Stokes (momentum conservation), continuity (mass conservation), and energy conservation equations. This type of problem requires the addition of the Acoustics Module.
- Geometrical acoustics—at high frequencies when the typical wavelength becomes comparable with the geometrical features, standard finite element methods are no longer appropriate. Instead the acoustic field can

be solved using ray tracing methods or energy methods. The Ray Acoustics and Acoustic Diffusion Equation interfaces apply here. This type of problem requires the addition of the Acoustics Module.

Mathematical Models for Acoustic Analysis

Standard acoustic problems involve solving for the small acoustic pressure variations p on top of the stationary background pressure p_0 . Mathematically this represents a linearization (small parameter expansion) around the stationary quiescent values.

The governing equations for a compressible lossless (no thermal conduction and no viscosity) fluid flow problem are the momentum equation (Euler's equation) and the continuity equation. These are given by:

$$\begin{aligned}\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{u} &= -\frac{1}{\rho} \nabla p \\ \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) &= 0\end{aligned}$$

where ρ is the total density, p is the total pressure, and \mathbf{u} is the velocity field. In classical pressure acoustics, all thermodynamic processes are assumed reversible and adiabatic, known as an isentropic process. The small parameter expansion is performed on a stationary fluid of density ρ_0 (SI unit: kg/m³) and at pressure p_0 (SI unit: Pa) such that:

$$\begin{aligned}p &= p_0 + p' & p' \ll p_0 \\ \rho &= \rho_0 + \rho' & \text{with} & \rho' \ll \rho_0 \\ \mathbf{u} &= \mathbf{0} + \mathbf{u}'\end{aligned}$$

where the primed variables represent the small acoustic variations. Inserting these into the governing equations and only retaining terms linear in the primed variables yields:

$$\begin{aligned}\frac{\partial \mathbf{u}'}{\partial t} &= -\frac{1}{\rho_0} \nabla p' \\ \frac{\partial \rho'}{\partial t} + \rho_0 (\nabla \cdot \mathbf{u}') &= 0\end{aligned}$$

One of the dependent variables, the density, is removed by expressing it in terms of the pressure using a Taylor expansion (linearization)

$$\rho' = \left. \frac{\partial \rho_0}{\partial p} \right|_s p' = \frac{1}{c_s^2} p'$$

where c_s is recognized as the (isentropic) speed of sound (SI unit: m/s) at constant entropy s . The subscripts s and 0 are dropped in the following.

Finally, rearranging the equations (divergence of momentum equation inserted into the continuity equation) and dropping the primes yields the wave equation for sound waves in a lossless medium

$$\frac{1}{\rho c^2} \frac{\partial^2 p}{\partial t^2} + \nabla \cdot \left(-\frac{1}{\rho} (\nabla p - \mathbf{q}_d) \right) = Q_m \quad (11-1)$$

The speed of sound is related to the compressibility of the fluid where the waves are propagating. The combination ρc^2 is called the *bulk modulus*, commonly denoted K (SI unit: N/m²). The equation is further extended with two optional source terms:

- The *dipole source* \mathbf{q}_d (SI unit: N/m³)
- The *monopole source* Q_m (SI unit: 1/s²)

A special case is a time-harmonic wave, for which the pressure varies with time as

$$p(\mathbf{x}, t) = p(\mathbf{x})e^{i\omega t}$$

where $\omega = 2\pi f$ (SI unit: rad/s) is the angular frequency and f (SI unit: Hz) is denoting the frequency. Assuming the same harmonic time-dependence for the source terms, the wave equation for acoustic waves reduces to an inhomogeneous Helmholtz equation

$$\nabla \cdot \left(-\frac{1}{\rho} (\nabla p - \mathbf{q}_d) \right) - \frac{\omega^2 p}{\rho c^2} = Q_m. \quad (11-2)$$

With the two source terms removed, this equation can also be treated as an eigenvalue PDE to solve for eigenmodes and eigenfrequencies.

Typical boundary conditions for the wave equation and the Helmholtz equation are:

- Sound-hard boundaries (walls)
- Sound-soft boundaries
- Impedance boundary conditions
- Radiation boundary conditions

In lossy media, an additional term of first order in the time derivative needs to be introduced to model attenuation of the sound waves

$$\frac{1}{\rho c^2} \frac{\partial^2 p}{\partial t^2} - d_a \frac{\partial p}{\partial t} + \nabla \cdot \left(-\frac{1}{\rho} (\nabla p - \mathbf{q}_d) \right) = Q_m$$

where d_a is the damping coefficient. Note also that even when the sound waves propagate in a lossless medium, attenuation frequently occurs by interaction with the surroundings at the boundaries of the system.

The Pressure Acoustics, Frequency Domain Interface

The **Pressure Acoustics, Frequency Domain (acpr)** interface (), found under the **Pressure Acoustics** branch () when adding a physics interface, is used to compute the pressure variation for propagation of acoustic waves in fluids at quiescent background conditions. It is suited for all frequency-domain simulations with harmonic variations of the pressure field.

The physics interface can be used for linear acoustics described by a scalar pressure variable. It includes domain conditions to model losses in a homogenized way, so-called fluid models for porous materials, as well as losses in narrow regions. Domain features also include background incident acoustic fields as well as domain monopole and dipole sources. The plane wave attenuation behavior of the acoustic waves may be entered as a user-defined quantity, or defined to be bulk viscous and thermal losses.

The physics interface solves the Helmholtz equation in the frequency domain for given frequencies, or as an eigenfrequency or modal analysis study.

An acoustics model can be part of a larger multiphysics model that describes, for example, the interactions between structures and acoustic waves. This physics interface is suitable for modeling acoustics phenomena that do not involve fluid flow.

The sound pressure p , which is solved for in pressure acoustics, represents the acoustic variations (or excess pressure) to the ambient pressure. In the absence of flow, the ambient pressure is simply the static absolute atmospheric pressure of 10^5 Pa.

When the geometrical dimensions of the acoustic problems are reduced from 3D to 2D (planar symmetry or axisymmetric) or to 1D axisymmetric, it is possible to specify an out-of-plane wave number k_z and a circumferential wave number m , when applicable. In this case the wave number used in the equations k_{eq} contains both the ordinary wave number k as well as the out-of-plane wave number and circumferential wave number, when applicable.

The following table lists the names and SI units for the most important physical quantities in the Pressure Acoustics, Frequency Domain interface:

TABLE II-1: PRESSURE ACOUSTICS, FREQUENCY DOMAIN INTERFACE PHYSICAL QUANTITIES

QUANTITY	SYMBOL	SI UNIT	ABBREVIATION
Pressure	p	Pascal	Pa
Density	ρ	kilogram/meter ³	kg/m ³
Frequency	f	Hertz	Hz
Wave number	k	1/meter	1/m
Dipole source	\mathbf{q}_d	newton/meter ³	N/m ³
Monopole source	Q_m	1/second ²	1/s ²
Speed of sound	c	meter/second	m/s
Specific acoustic impedance	Z	pascal-second/meter	Pa·s/m
Normal acceleration	a_n	meter/second ²	m/s ²
Source location	r_0	meter	m
Wave direction	\mathbf{n}_k	(dimensionless)	1

In the following descriptions of the functionality in this physics interface, the subscript c in ρ_c and c_c (the density and speed of sound, respectively) denotes that these can be complex-valued quantities in models with damping.

When this physics interface is added, these default nodes are also added to the **Model Builder**—**Pressure Acoustics Model**, **Sound Hard Boundary (Wall)**, and **Initial Values**.

Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and point conditions. You can also right-click **Pressure Acoustics** to select physics features from the context menu.

Physics Nodes — Equation Section

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the name string must be unique. Only letters, numbers, and underscores (`_`) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `acpr`.

EQUATION

Expand the **Equation** section to see the equations solved for with the **Equation form** specified. The default selection is **Equation form** set to **Study controlled**. The available studies are selected under **Show equations assuming**.

- For **Study controlled**, the scaling and nonreflecting boundary settings are optimized for the numerical performance of the different solvers.
- For **Frequency domain**, enter the settings as described in [Scaling Factor and Nonreflecting Boundary Condition Approximation](#).

PRESSURE ACOUSTICS EQUATION SETTINGS

- For 1D axisymmetric components, the default **Out-of-plane wave number** k_z (SI unit: rad/m) is 0 rad/m. The default **Circumferential wave number** m (dimensionless) is 0. The pressure has the form:

$$p(r, \varphi, z) = p(r)e^{-i(k_z z + m\varphi)}$$

- For 2D axisymmetric components, the default **Circumferential wave number** m (dimensionless) is 0. The pressure has the form:

$$p(r, \varphi, z) = p(r, z)e^{-im\varphi}$$

- For 2D components, the default **Out-of-plane wave number** k_z (SI unit: rad/m) is 0 rad/m. The pressure has the form:

$$p(x, y, z) = p(x, y)e^{-ik_z z}$$

Scaling Factor and Nonreflecting Boundary Condition Approximation

For all component dimensions, and if required, click to expand the **Equation** section, then select **Frequency domain** as the **Equation form** and enter the settings as described below.

The default **Scaling factor** Δ is $1/\omega^2$ and **Non-reflecting boundary condition approximation** is **Second order**. These values correspond to the equations for a Frequency Domain study when the equations are study controlled.

To get the equations corresponding to an Eigenfrequency study, change the **Scaling factor** Δ to 1 and the **Non-reflecting boundary conditions approximation** to **First order**.

SOUND PRESSURE LEVEL SETTINGS

The zero level on the dB scale varies with the type of fluid. That value is a reference pressure that corresponds to 0 dB. This variable occurs in calculations of the sound pressure level L_p based on the root mean square (rms) pressure p_{rms} , such that

$$L_p = 20 \log\left(\frac{p_{\text{rms}}}{p_{\text{ref}}}\right) \quad \text{with} \quad p_{\text{rms}} = \sqrt{\frac{1}{2} p p^*}$$

where p_{ref} is the reference pressure and the star (*) represents the complex conjugate. This is an expression valid for the case of harmonically time-varying acoustic pressure p .

Select a **Reference pressure for the sound pressure level** based on the fluid type:

- **Use reference pressure for air** to use a reference pressure of $20 \mu\text{Pa}$ ($20 \cdot 10^{-6}$ Pa).
- **Use reference pressure for water** to use a reference pressure of $1 \mu\text{Pa}$ ($1 \cdot 10^{-6}$ Pa).
- **User-defined reference pressure** to enter a reference pressure $p_{\text{ref}, \text{SPL}}$ (SI unit: Pa). The default value is the same as for air, $20 \mu\text{Pa}$.

DEPENDENT VARIABLES

This physics interface defines one dependent variable (field), the **Pressure** p . If required, edit the name, which changes both the field name and the dependent variable name. If the new field name coincides with the name of another pressure field in the model, the interfaces share degrees of freedom and dependent variable name. The new field name must not coincide with the name of a field of another type, or with a component name belonging to some other field.

DISCRETIZATION

To display additional settings beyond the shape function orders in this section, click the **Show** button () and select **Advanced Physics Options**.

	<ul style="list-style-type: none">• Domain, Boundary, Edge, Point, and Pair Nodes for the Pressure Acoustics, Frequency Domain Interface• Theory for Pressure Acoustics, Frequency Domain

Domain, Boundary, Edge, Point, and Pair Nodes for the Pressure Acoustics, Frequency Domain Interface

The **Pressure Acoustics, Frequency Domain Interface** has these domain, boundary, edge, point, and pair nodes, listed in alphabetical order, available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or by right-clicking to access the context menu (all users). Continuity in the total pressure is the default condition on interior boundaries.

	In general, to add a node, go to the Physics toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the Attributes menu.
---	---

- Axial Symmetry
- Continuity
- Cylindrical Wave Radiation
- Dipole Source
- Impedance
- Incident Pressure Field
- Interior Sound Hard Boundary (Wall)
- Initial Values
- Monopole Source
- Normal Acceleration
- Periodic Condition
- Plane Wave Radiation
- Pressure Acoustics
- Pressure
- Sound Hard Boundary (Wall)
- Sound Soft Boundary
- Spherical Wave Radiation
- Symmetry

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the component that is valid on the axial symmetry boundaries only.

See [Table 2-3](#) for links to common sections and [Table 2-4](#) for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Pressure Acoustics

The **Pressure Acoustics** node adds the equations for time-harmonic and eigenfrequency acoustics modeling in the frequency domain. In the **Settings** window, define the properties for the acoustics model and model inputs including temperature.

PRESSURE ACOUSTICS MODEL

The default **Fluid model** for pressure acoustics is a **Linear elastic** fluid. By default, the values for the **Density** ρ (SI unit: kg/m³) and the **Speed of sound** c (SI unit: m/s) are taken **From material**. For **User defined**, enter other values for these properties.

Sound Hard Boundary (Wall)

The **Sound Hard Boundary (Wall)** adds a boundary condition for a sound hard boundary or wall. This is a boundary where the normal component of the acceleration is zero, such that

$$-\mathbf{n} \cdot \left(-\frac{1}{\rho_0} (\nabla p - \mathbf{q}_d) \right) = 0$$

For zero dipole source and constant fluid density, this means that the normal derivative of the pressure is zero at the boundary

$$\frac{\partial p}{\partial \mathbf{n}} = 0$$

Sound-hard boundaries are available for all study types. Note that this condition is identical to the **Symmetry** condition.

Initial Values

The **Initial Values** node adds initial values for the sound pressure and the pressure time derivative that can serve as an initial guess for a nonlinear solver. If more than one initial value is needed, from the **Physics** toolbar click to add more **Initial Values** nodes.

INITIAL VALUES

Enter a value or expression for the initial values for the **Pressure** p (SI unit: Pa) and the **Pressure, first time derivative**, $\partial p/\partial t$ (SI unit: Pa/s). The defaults are 0 Pa and 0 Pa/s, respectively.

Monopole Source

Use the **Monopole Source** node to add the domain source term Q_m to the governing equation. A monopole source added to a domain has a uniform strength in all directions. In advanced models, this source term can, for example, be used to represent a domain heat source causing pressure variations. Add this node from the **More>** submenu.

MONOPOLE SOURCE

Enter a **Monopole source** Q_m (SI unit: 1/s²). The default is 0 1/s².

Dipole Source

Use the **Dipole Source** node to add the domain source term \mathbf{q}_d to the governing equation. This source is typically stronger in two opposite directions. In advanced models, this term can, for example, be used to represent a uniform constant background flow convecting the sound field. Add this node from the **More>** submenu.

DIPOLE SOURCE

Enter coordinates for the **Dipole source** \mathbf{q}_d (SI unit: N/m³). These are the individual components of the dipole source vector. The defaults are 0 N/m³.

Normal Acceleration

The **Normal Acceleration** adds an inward normal acceleration a_n :

$$-\mathbf{n} \cdot \left(-\frac{1}{\rho_0} (\nabla p - \mathbf{q}_d) \right) = a_n$$

Alternatively, specify the acceleration \mathbf{a}_0 of the boundary. The part in the normal direction is used to define the boundary condition:

$$\mathbf{n} \cdot \left(-\frac{1}{\rho_0} (\nabla p - \mathbf{q}_d) \right) = \mathbf{n} \cdot \mathbf{a}_0$$

This feature represents an external source term. It can also be used to manually couple acoustics with a structural analysis for modeling acoustic-structure interaction.

NORMAL ACCELERATION

Select a **Type—Inward Acceleration** (the default) or **Acceleration**.

- For **Inward Acceleration**, enter the value of the **Inward acceleration** a_n (SI unit: m/s²). The default is 0 m/s². Use a positive value for inward acceleration or a negative value for outward acceleration.
- For **Acceleration**, enter values for the components of the **Acceleration** \mathbf{a}_0 (SI unit: m/s²). The defaults are 0 m/s².

Sound Soft Boundary

The **Sound Soft Boundary** adds a boundary condition for a sound soft boundary, where the acoustic pressure vanishes: $p = 0$. It is an appropriate approximation for a liquid-gas interface and in some cases for external waveguide ports.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Pressure

The **Pressure** node creates a boundary condition that acts as a pressure source at the boundary, which means a constant acoustic pressure p_0 is specified and maintained at the boundary: $p = p_0$. In the frequency domain, p_0 is the amplitude of a harmonic pressure source. The node is also available from the **Pairs** submenu as an option at interfaces between parts in an assembly.

PRESSURE

Enter the value of the **Pressure** p_0 (SI unit: Pa). The default is 0 Pa.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Impedance

The **Impedance** node adds an impedance boundary condition, which is a generalization of the sound-hard and sound-soft boundary conditions:

$$-\mathbf{n} \cdot \left(-\frac{1}{\rho_c} (\nabla p_t - \mathbf{q}_d) \right) = -\frac{i\omega p_t}{Z_i}$$

Here Z_i is the acoustic input impedance of the external domain and it has the unit of a specific acoustic impedance. From a physical point of view, the acoustic input impedance is the ratio between the local pressure and local normal particle velocity.

The Impedance boundary condition is a good approximation for a locally reacting surface—a surface for which the normal velocity at any point depends only on the pressure at that exact point.

In the two opposite limits $Z_i \rightarrow \infty$ and $Z_i \rightarrow 0$, this boundary condition is identical to the [Sound Hard Boundary \(Wall\)](#) condition and the [Sound Soft Boundary](#) condition, respectively.

IMPEDANCE

The **Impedance model** available is **User defined**.

Enter the value of the **Impedance** Z_i (SI unit: Pa·s/m). The default value is set to the specific impedance of air 1.2 kg/m³·343 m/s.

Symmetry

The **Symmetry** node adds a boundary condition where there is symmetry in the pressure. Use this condition to reduce the size of a model by cutting it in half where there are symmetries. In pressure acoustics, this boundary condition is mathematically identical to the [Sound Hard Boundary \(Wall\)](#) condition.

Plane Wave Radiation

The **Plane Wave Radiation** node adds a radiation boundary condition for a plane wave. If required, from the **Physics** toolbar, add an [Incident Pressure Field](#) to model an incoming wave. This radiation condition allows an outgoing plane wave to leave the modeling domain with minimal reflections when the angle of incidence is near to normal.

The *plane wave* type is suitable for both far-field boundaries and ports. Because many waveguide structures are only interesting in the plane-wave region, it is particularly relevant for ports. When using the radiation condition on an open far-field boundary, it is recommended to construct the boundary such that the incidence angle is near to normal. This of course requires a priori knowledge of the problem and the solution.

- An estimate of the reflection coefficient R_s , for the spurious waves reflecting off the plane wave radiation boundary, is, for incident plane waves at angle θ , given by the expression:

$$R_s = \left| \frac{\cos \theta - 1}{\cos \theta + 1} \right|^N$$

where N is the order of the boundary condition (here 1 or 2). So at normal incidence ($\theta = 0$) there are no spurious reflections, while at an incidence angle of 30° for $N = 2$ (plane wave radiation in the frequency domain), for example, the amplitude of the spurious reflected wave is 0.5% of the incident.

Automotive Muffler: Application Library path
COMSOL_Multiphysics/Acoustics/automotive_muffler

Spherical Wave Radiation

The **Spherical Wave Radiation** node adds a radiation boundary condition for a spherical wave, for which you define the source location. If required, from the **Physics** toolbar add an [Incident Pressure Field](#) to model an incoming wave. This radiation condition allows an outgoing spherical wave to leave the modeling domain with minimal reflections. The geometry of the modeling domain should be adapted to have the outgoing spherical waves coincide with the boundary. This is in order to minimize spurious reflections.

Spherical Wave Radiation

Enter coordinates for the **Source location** r_0 (SI unit: m). The defaults are 0 m.

Cylindrical Wave Radiation

The **Cylindrical Wave Radiation** node adds a radiation boundary condition for a cylindrical wave, for which you define the source location and the source axis direction. If required, from the **Physics** toolbar, add an [Incident Pressure Field](#) to model an incoming wave. This radiation condition allows an outgoing cylindrical wave to leave the modeling domain with minimal reflections. The geometry of the modeling domain should be adapted to have the outgoing cylindrical waves coincide with the boundary. This is in order to minimize spurious reflections.

Cylindrical Wave Radiation

Enter coordinates for the **Source location** r_0 (SI unit: m) (the defaults are 0 m) and the **Source axis** direction r_{axis} (dimensionless) (the defaults are 0).

Incident Pressure Field

The **Incident Pressure Field** node is a subnode to all nonreflecting boundary conditions (plane, cylindrical, or spherical wave radiation). From the **Physics** toolbar, add to [Plane Wave Radiation](#), [Spherical Wave Radiation](#), or [Cylindrical Wave Radiation](#) nodes. If the incident pressure field p_i is a predefined plane wave, it is of the type:

$$p_i = p_0 e^{-i(\mathbf{k} \cdot \mathbf{r})} = p_0 e^{-ik_{eq}(\frac{\mathbf{r} \cdot \mathbf{e}_k}{\|\mathbf{e}_k\|})}$$

where p_0 is the wave amplitude, \mathbf{k} is the wave vector (with amplitude $k_{eq}=|\mathbf{k}|$ and wave direction vector \mathbf{e}_k), and \mathbf{r} is the location on the boundary. The incident pressure field can also be a user-defined value or expression.

INCIDENT PRESSURE FIELD

From the **Incident pressure field type** list, select **Plane wave** to define an incident pressure field of plane wave type. Then enter a **Pressure amplitude** p_0 (SI unit: Pa) (the default is 0 Pa) and **Wave direction** \mathbf{e}_k (SI unit: m).

Select **User defined** to enter the expression for the **Incident pressure field** p_i (SI unit: Pa) as a function of space. The default is 0 Pa.

Interior Sound Hard Boundary (Wall)

The **Interior Sound Hard Boundary (Wall)** node adds a boundary condition for a sound hard boundary or wall on interior boundaries. A sound-hard boundary is a boundary at which the normal component of the acceleration is zero:

$$-\mathbf{n} \cdot -\left(\frac{1}{\rho_c}(\nabla p_t - \mathbf{q}_d)\right)_1 = 0 \quad -\mathbf{n} \cdot \left(\left(-\frac{1}{\rho_c}\right)(\nabla p_t - \mathbf{q}_d)\right)_2 = 0$$

where the subscripts 1 and 2 represent the two sides of the boundary. For zero dipole charge and constant fluid density, this means that the normal derivative of the pressure is zero at the boundary. On an interior sound hard boundary, the pressure is not continuous but is treated as a so-called slit feature.

Periodic Condition

The **Periodic Condition** node adds a periodic boundary condition that can be used to reduce the model size by using symmetries and periodicities in the geometry and physics interfaces being modeled. This feature works well for cases like opposing parallel boundaries. In other cases use a **Destination Selection** subnode to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

PERIODICITY SETTINGS

Select a **Type of periodicity**: **Continuity** (the default) or **Antiperiodicity**.

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See [Constraint Settings](#) for more information.

ORIENTATION OF SOURCE

To display this section, click the **Show** button () and select **Advanced Physics Options**. For information about the **Orientation of Source** section, see [Orientation of Source and Destination](#).

Axial Symmetry

The **Axial Symmetry** node is a default node added for all 2D and 1D axisymmetric components. The boundary condition is active on all boundaries on the symmetry axis.

Continuity

Continuity is available as an option at interfaces between parts in a pair.

This condition gives continuity in total pressure and in the normal acceleration over the pair (subscripts 1 and 2 in the equation refer to the two sides in the pair):

$$-\mathbf{n} \cdot \left[-\left(\frac{1}{\rho_c} (\nabla p_t - \mathbf{q}_d) \right)_1 - \left(-\frac{1}{\rho_c} (\nabla p_t - \mathbf{q}_d) \right)_2 \right] = 0$$

CONSTRAINT SETTINGS

To display this section, click the **Show** button () and select **Advanced Physics Options**.

Theory for Pressure Acoustics, Frequency Domain

The Pressure Acoustics, Frequency Domain Interface is designed for the analysis of various types of pressure acoustics problems in the frequency domain, all concerning pressure waves in a fluid. An acoustics model can be part of a larger multiphysics model that describes, for example, the interactions between structures and acoustic waves. This physics interface is suitable for modeling acoustics phenomena that do not involve fluid flow.

This physics interface solves for the acoustic pressure, p . It is available in all space dimensions—for 3D, 2D, and 1D Cartesian geometries as well as for 2D and 1D axisymmetric geometries.

These studies are discussed briefly in this section:

- [Frequency Domain Study](#)
- [Eigenfrequency Study](#)
- [References for the Pressure Acoustics, Frequency Domain Interface](#)

Frequency Domain Study

The frequency domain—or time-harmonic—formulation uses the following inhomogeneous Helmholtz equation:

$$\nabla \cdot \left(-\frac{1}{\rho_c} (\nabla p - \mathbf{q}_d) \right) - \frac{\omega^2 p}{\rho_c c_c^2} = Q_m \quad (11-3)$$

In this equation, $p = p(\mathbf{x}, \omega)$ (the dependence on ω is henceforth not explicitly indicated). With this formulation you can compute the frequency response of a system for a number of frequencies. The default frequency domain study sets up a parametric sweep over a frequency range using a harmonic load.

When there is damping, ρ_c and c_c are complex-valued quantities.

[Equation 11-3](#) is the equation that the software solves for 3D geometries. In lower-dimensional and axisymmetric cases, restrictions on the coordinate dependence mean that the equations differ from case to case. Here is a brief summary of the situation.

2 D

In 2D, the pressure is of the form

$$p(\mathbf{r}) = p(x, y) e^{-ik_z z}$$

which, inserted in [Equation 11-3](#), gives

$$\nabla \cdot \left(-\frac{1}{\rho_c} (\nabla p - \mathbf{q}_d) \right) - \frac{1}{\rho_c} \left(\frac{\omega^2}{c_c^2} - k_z^2 \right) p = Q_m \quad (11-4)$$

The *out-of-plane wave number*, k_z , can be set on the Pressure Acoustics page. By default its value is 0. In the mode analysis type, $-ik_z$ is used as the eigenvalue.

2 D AXISYMMETRY

For 2D axisymmetric geometries, the independent variables are the radial coordinate, r , and the axial coordinate, z . The only dependence allowed on the azimuthal coordinate, ϕ , is through a phase factor,

$$p(r, \phi, z) = p(r, z) e^{-im\phi} \quad (11-5)$$

where m denotes the *circumferential wave number*. Because the azimuthal coordinate is periodic, m must be an integer. Just like k_z in the 2D case, m can be set on the Settings window for Pressure Acoustics.

As a result of [Equation 11-5](#), the equation to solve for the acoustic pressure in 2D axisymmetric geometries becomes

$$\frac{\partial}{\partial r} \left[-\frac{r}{\rho_c} \left(\frac{\partial p}{\partial r} - q_r \right) \right] + r \frac{\partial}{\partial z} \left[-\frac{1}{\rho_c} \left(\frac{\partial p}{\partial z} - q_z \right) \right] - \left[\left(\frac{\omega}{c_c} \right)^2 - \left(\frac{m}{r} \right)^2 \right] \frac{rp}{\rho_c} = r Q_m$$

1D AXISYMMETRY

In 1D axisymmetric geometries,

$$p(r, \phi, z) = p(r) e^{-i(k_z z + m \phi)}$$

leading to the radial equation

$$\frac{\partial}{\partial r} \left[-\frac{r}{\rho_c} \left(\frac{\partial p}{\partial r} - q_r \right) \right] - \left[\left(\frac{\omega}{c_c} \right)^2 - \left(\frac{m}{r} \right)^2 - k_z^2 \right] \frac{rp}{\rho_c} = r Q_m$$

where both the circumferential wave number m , and the *axial wave number* k_z , appear as parameters.

1D

The equation for the 1D case is obtained by taking the pressure to depend on a single Cartesian coordinate, x :

$$\frac{d}{dx} \left(-\frac{1}{\rho_c} \left(\frac{dp}{dx} - q_d \right) \right) - \frac{\omega^2}{\rho_c c_c^2} p = Q_m$$

Eigenfrequency Study

In the eigenfrequency formulation, the source terms are absent, and the eigenmodes and eigenfrequencies are solved for:

$$\nabla \cdot \left(-\frac{1}{\rho_c} \nabla p \right) + \frac{\lambda^2 p}{\rho_c c_c^2} = 0 \quad (11-6)$$
